Submitted by **MICHAEL V. PLUMMER**, Department of Biology, Box 12251, Harding University, Searcy, Arkansas 72149, USA (e-mail: plummer@harding.edu) and **DONALD F. MCKENZIE,** Wildlife Management Institute, 2396 Cocklebur Road, Ward, Arkansas 72176, USA (e-mail: wmidm@ipa.net).

RANA CATESBEIANA (Bullfrog). ECUADOR: PROVINCIA DE NAPO: Carretera Puyo-Tena, ca. 50 km (by road) from Puyo (ca. 77°50'W, 01°08'S, ca. 400 m elev.). 18 March 2000. D. F. Cisneros-Heredia, M. Brandt, A. Chiriboga, G. Reck. Universidad San Francisco de Quito, Quito (DFCH-USFQ 750; juvenile active at 1830 h in flooded grassland, ca. 100 m from an abandoned bullfrog farm). Verified by J. M. Touzet. *Rana catesbeiana* was introduced to Ecuador in 1988 with the importation of 100 adults and 70,000 tadpoles for commercial purposes; and although initially the bullfrog farms were located in western Ecuador, now they are spread along the western and eastern lowlands (ECOLAP. 1998. El Manejo para la Protección y el Uso Sustentable de la Vida Silvestre en el Ecuador. Proyecto INEFAN/GEF act. 20, Quito; Cano et al. 2000. *In* La Biodiversidad del Ecuador Informe 2000. Ministerio del Ambiente, EcoCiencia and IUCN.). Specimen reported herein is the first of this alien taxon from outside of farms. This record and observations in the surroundings of Bahía de Caráquez (ca. 80°20'W, 00°40'S, ca. 8 m elev.), province of Manabí, confirm that Bullfrogs are escaping and probably establishing feral populations in Ecuador (tadpoles and amplectant pairs were observed in ditches at the locality in the province of Napo).

Submitted by **DIEGO F. CISNEROS-HEREDIA**, College of Biological and Environmental Sciences, Universidad San Francisco de Quito, Ave. Interoceánica y calle Diego de Robles, Campus Cumbayá, Edif. Maxwell, Casilla Postal 17-12-841, Quito, Ecuador; e-mail: diegofrancisco_cisneros@yahoo.com.

RANA CLAMITANS (Green Frog). USA: TENNESSEE: CANNON Co: Cooper Hollow. Captured near a small pond in pasture off Sinks Miller Road, ca. 1 km W Burt-Burgen Road. 17 September 2004. J. L. Miller. Verified by B. T. Miller. Middle Tennessee State University (MTSU 131A). New county record. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee, Misc. Publ. No. 12, Austin Peay State University, 89 pp.).

Submitted by **JOYCE L. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

RANA SYLVATICA (Wood Frog). USA: TENNESSEE: HOUSTON Co: North floodplain of Whiteoak Creek at stream mile 8, ca. 100 m SE of Lewis Branch Road, 1.8 road km SE of junction of Lewis Branch Road and Cooley Ford Road (36°14'55"N,87°49'05"W). 2 April 2004. Josh Ennen. Austin Peay State University Museum of Zoology (APSU 17500). 17 tadpoles found along with *Ambystoma maculatum* egg masses in road-rut pool in deciduous woods beside creek. HUMPHREYS Co: Concord Community, Tennessee Ridge Road, 0.6 km S of junction with Gander Branch Road (36°13'34"N,87°45'50"W). 29 April 2004. Josh Ennen and Nathan Parker. APSU 17501. Two tadpoles in road-rut pool just E of highway. All specimens verified by A. Floyd Scott. New county records that extend range of the species in Tennessee to the western edge of the Western Highland Rim (Redmond and Scott. 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. (Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996), http://www.apsu.edu/amatlas/, accessed 1 September 2004). Collections made under authority of Tennessee Wildlife Resources Agency Permit 1662; field work was supported by Austin Peay State University's Center for Field Biology.

Submitted by **JOSH ENNEN** and **NATHAN PARKER**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA, ennenj@apsu.edu.

SPEA HAMMONDII (Western Spadefoot). USA: CALIFORNIA: VENTURA Co.: Simi Valley: Tadpoles observed in cattle pond in rolling hills supporting grasslands and sage scrub, ca. 3.6 km NE of the intersection of Brea Canyon and State Route 118 (NAD 83: UTM Zone 11S: 3797296mN, 336543mE, 320 m elev.). 15 March 2000. One collected by Robert B. Johnson III. CAS 228523. Hundreds of recently metamorphosed juveniles emerging from vernal pool in similar habitat ca. 1.8 km NW of intersection of Alamos Canyon and State Route 118 (NAD 83 UTM Zone 11S: 3797004mN, 332238mE, 285 m elev.). 22 April 2003. One salvaged by Sandra J. Leatherman. CAS 228524. Both specimens verified by Robert Fisher. New county records (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Department of Fish and Game, Inland Fisheries Division. Contract No. 8023). Numerous records exist from the surrounding counties of Los Angeles, Santa Barbara, and Kern.

Submitted by **BRIAN M. LEATHERMAN**, White & Leatherman BioServices, 4848 Lakeview Drive, Suite 100E, Yorba Linda, California 92886, USA.

SYRRHOPHUS CYSTIGNATHOIDES CAMPI (Rio Grande Chirping Frog). USA: TEXAS: WILSON CO.: Eagle Creek Ranch Subdivision, near intersection of Cherry Ridge and Palo Alto; 29°15.339'N, 98°12.668'W. 29 June 2004. Adult collected under a board at 1930 h during light rain. TNHC 63067. Verified by Travis LaDuc. First county record, shows continued expansion of range from Lower Rio Grande Valley, presumably from inadvertent human transport (Dixon 2000. Amphibians and Reptiles of Texas, 2nd edition, Texas A&M University Press, 421 pp.). Individuals heard calling at same location in May 2004. Record marks tenth county in Texas outside of native range of *S. cystignathoides* (thought to be restricted to Cameron and Hidalgo counties). This locality is ca. 3 mi from Bexar County, where the species had been recorded previously.

Submitted by **FRANZ J. SCHMIDT**, 562 Cherry Ridge, Floresville, Texas 78114, USA.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Eastern Snapping Turtle). USA: TEXAS: LEE CO.: Yegua Knobbs Preserve (30°20.323'N, 97°11.050'W). 2 May 2004. Caught in pond at the preserve. William B. Montgomery. Verified by Travis LaDuc. University of Texas Natural Hisory Collection (TNHC 63004, color slide). New county record (Dixon 2000. Amphibians and Reptiles of Texas. Second Ed. Texas A&M Press, viii + 421 pp.).

Submitted by **WILLIAM B. MONTGOMERY**, P.O. Box 656, Elgin, Texas 78621, USA; e-mail: montgomery6@earthlink.net.

PSEUDEMYS GORZUGI (Rio Grande River Cooter). USA: TEXAS: MAVERICK CO.: 4 km SE of Jimeacutenez, Coahuila, Mexico (29°00'42"N, 100°38'34"W). 11 July 2003. M. R. J. Forstner and Josephine Duvall. Verified by J. R. Dixon. Texas A&M University, Texas Cooperative Wildlife Collection, TCWC 88216. New county record. The juvenile female was collected in an agricultural irrigation waterway. The specimen had a carapace length of 72.3 mm, a carapace width of 65.4 mm, a plastron length of 62.1 mm, a plastron width of 50.1 mm, a shell depth of 31.2 mm, and weighed 71 g.

Submitted by **LINDLEY BAILEY** and **M. R. J. FORSTNER**, Department of Biology, Texas State University, 601 University Drive, San Marcos, Texas 78666, USA; e-mail [LB]: lb1122@txstate.edu.

TERRAPENE ORNATA (Ornate Box Turtle). USA: ARKANSAS: COLUMBIA Co: Hwy 79, 3 km SE McNeil, Sec. 5 T16S R20W. June 1992. Jim Gann. Henderson State University collection 832. Distribution into southwestern Arkansas is indicated by Conant and Collins (1998. Reptiles and Amphibians Eastern/Central North America, 3rd ed., Houghton Mifflin Co., Boston, Massachusetts) but no records are shown in Trauth et al. (2004. The Amphibians and Reptiles of Arkansas, Univ. Arkansas Press, Fayetteville). Specimen provides verification of the species in southwestern Arkansas.

Submitted by **JIM GANN,** Logoly State Park, McNeil, Arkansas 71752, USA, and **RENN TUMLISON**, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA; e-mail: tumlison@hsu.edu.

LACERTILIA

AMPHISBAENA MUNOAI (NCN). BRAZIL: RIO GRANDE DO SUL: Municipality of Três Passos (53°55'55"S, 27°27'20"W). October 1981. J. R. Collares. Herpetological collection of the Museu de Ciências e Tecnologia of the Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil. (MCP 1457). Municipality of Santo Cristo (54°39'46"S, 27°49'26"W), collected by students of a local school (no additional data available) (MCP 11636). Verified by R. Baptista de Oliveira. *Amphisbaena munoai* was known to occur from Passo Fundo, northern Rio Grande do Sul, Brazil, to southern and central Uruguay (Gans 1966. Bull. Amer. Mus. Nat. Hist. 134[3]:187–260). Northwesternmost record for the species, the record in Três Passos extends the known range ca. 227 km NW from Passo Fundo (Gans, *op. cit.*).

Submitted by **JORGE S. BERNARDO-SILVA** (e-mail: 98203483@pucrs.br) and **MARCOS DI-BERNARDO**, Laboratório de Herpetologia, Faculdade de Biociências and Museu de Ciências e Tecnologia of the Pontifícia Universidade Católica do Rio Grande do Sul (PUCRS), Av. Ipiranga, 6681, 90619-900 Porto Alegre, Rio Grande do Sul, Brazil (e-mail: [MDB] madibe@pucrs.br).

ASPIDOSCELIS (= CNEMIDOPHORUS) NEOMEXICANA: (New Mexico Whiptail). USA: NEW MEXICO: LINCOLN CO., prairie dog town in Taylor Draw, ca. 12 air mi SW Carrizozo (T8S R8E SE1/4 Sec 27). 23 June 2004. D. W. Burkett, M. Hartsough, and M. Swink. University of New Mexico Museum of Southwestern Biology (MSB 71138). Verified by C. W. Painter. County record (Degenhardt et al. 1996. The Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque).

Submitted by **DOUGLAS W. BURKETT, MATT HARTSOUGH, MIKE SWINK,** P.O. Box 399, White Sands Missile Range, New Mexico 88002, USA.

CNEMIDOPHORUS LACERTOIDES. BRAZIL: SANTA CATARINA: FLORIANÓPOLIS MUNICIPALITY: Ilha de Santa Catarina: Restinga da Joaquina (27°35'36"S; 48°35'56"W). 8–10 December 2003. C. F. D. Rocha, D. Vrcibradic, V. A. Menezes, and C. V. Ariani. Museu Nacional, Rio de Janeiro (MNRJ 11289–303). Verified by G. Skuk and G. Scrocchi. This species has been reported to occur in Uruguay, Argentina, and southern Brazil, where it was previously known only from the state of Rio Grande do Sul (Maslin and Secoy 1986. Contr. Zool., Univ. Colorado Mus. 1:1–60; Lema 1994. Comunic. Mus. Ciênc. Tecnol. PUCRS, Sér. Zool. 7:41–150). This note provides the first record for the state of Santa Catarina and the northernmost record for the species. It extends the distribution ca. 300 km NE from the previous northernmost locality (Torres, on the northern coast of Rio Grande do Sul state; Lema, *op. cit.*).

Submitted by **DAVOR VRCIBRADIC, CARLOS FREDERICO D. ROCHA, VANDERLAINE AMARAL DE MENEZES,** and **CRISTINA VALENTE ARIANI,** Departamento de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, 20550-011, Rio de Janeiro, RJ, Brazil.

CNEMIDOPHORUS SERRANUS. ARGENTINA: SAN LUIS: CORONEL PRINGLES: campground on the shore of Embalse La Florida. 25 December 2003. E. C. G. López. Herpetological Collection Museo de La Plata, La Plata, Buenos Aires, (MLPS 2574). Verified by J. C. Acosta. First province record (Avila and Carrizo 2003. Acta Zool. Lilloana 47[1–2]:93–115), and westernmost record for the species, extending known range 139 km W from El Chacay, Rio Cuarto Department, Cordoba Province (Martori and Aun 1995. Acta Zool. Lilloana 43[1]:87–97). Previously known only from the eastern slope of Sierras Grandes de Córdoba Mountains and related formations in Córdoba Province.

Submitted by: **CRISTIAN HERNAN FULVIO PEREZ** (e-mail: liolaemu@criba.edu.ar), Julián Álvarez 1182 "A," 8000 Bahía Blanca, Buenos Aires, Argentina; **EBER CRISTIAN GASTON LOPEZ** (e-mail: gclopez@criba.edu.ar), Barrio Los Paraísos, Manzana 262, Casa 4, 5700, San Luis, Argentina; and **LUCIANO JAVIER AVILA** (e-mail: avila@cenpat.edu.ar), CENPAT-CONICET, Boulevard Almirante Brown s/n, U9120ACV, Puerto Madryn, Chubut, Argentina.

EUMECES FASCIATUS (Five-lined Skink). USA: ARKANSAS: LONOKE CO: 2.2 km E. Ward (T5N, R9W, S25). 22 August 2004. Kelly E. McKenzie. Verified by Stanley E. Trauth. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 28735). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MICHAEL V. PLUMMER**, Department of Biology, Box 12251, Harding University, Searcy, Arkansas 72149, USA (e-mail: plummer@harding.edu) and **DONALD F. McKENZIE,** Wildlife Management Institute, 2396 Cocklebur Road, Ward, Arkansas 72176, USA (e-mail: wmidm@ipa.net).

EUMECES FASCIATUS (Five-lined Skink). USA: WISCONSIN: CRAWFORD CO.: Hwy F, 4 km SE of Lynxville. 5 September 2002. Brenda and Richard Rozelle. Photograph HDW-NIU 2002.10. Sect. 36 R6WT9N. Verified by Julie Ray. New county record. Extends the state distribution SW 60 km from the eastern Iowa and Sauk county records, and 105 km from Juneau Co. to the northeast. All three of these counties are within the unglaciated drift less area of Wisconsin of Casper (1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin, Milwaukee Public Mus. Interim Report of the Wisconsin Herpetological Atlas Project, 87 pp.) Found basking on a woodpile. In conversing with local naturalist Bill Peterson and other individuals from the area, HDW was informed that occasional specimens have been observed on the bluffs overlooking the Mississippi River at Lynxville and nearby areas.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA (e-mail: hdw@niu.edu), and **BRENDA L. ROZELLE**, N835 Hwy N.,Whitwater, Wisconsin 53190, USA.

GONATODES PETERSI. VENEZUELA: ZULIA: Municipio Mara, Sierra de Perijá, Fundo "La Orchila" (10°48'N, 72°21'W), 230 m. 29 May 2004. C. Hernández González. Museo de Biología de La Universidad del Zulia, Maracaibo (MBLUZ-R-0799). Verified by T. Barros Blanco. This poorly known gekkonid is an en-

demic from the Perijá Range, previously known from La Misión del Tokuko, Kasmera, and Kunana—localities on the eastern slopes of the southern Perijá Range (Donoso-Barros 1967. Notic. Mens. Mus. Nac. Hist. Nat. Santiago de Chile 11[129]: one page unnumbered.; Donoso-Barros 1968. Carib. J. Sci. 8[3–4]:105–122.; Peters and Donoso-Barros 1986. Catalogue of the Neotropical Squamata. Part II. Lizards and Amphisbaenians [Revised Edition], Smithsonian Institution Press, Washington D.C., 293 pp.; Rivero-Blanco 1979. The Neotropical Lizard Genus *Gonatodes* Fitzinger [Sauria: Spaherodactylinae]. Unpubl. Ph.D. thesis, Department of Biology, Texas A&M University, Texas, 233 pp.). Northernmost locality for this species, extending the distribution ca. 117 km (airline) N from the known range.

Submitted by **FERNANDO J. M. ROJAS-RUNJAIC** (e-mail: rojas_fernando@hotmail.com) and **EDWIN E. INFANTE RIVERO** (e-mail: edwinfantembluz@hotmail.com), La Universidad del Zulia, Facultad Experimental de Ciencias, Museo de Biología de La Universidad del Zulia, Sección de Herpetología, Apartado Postal 526, Maracaibo 4011, Venezuela.

HEMIDACTYLUS LONGICEPHALUS (Long-headed Tropical House Gecko). EQUATORIAL GUINEA: PROVINCE WELE-NZAS: Parque Nacional Los Altos de Nsork: 01°13'52.4"N, 11°00'53.4"E, 600 m asl. 4 April 2003. Twan Leenders. Yale Peabody Museum of Natural History (YPM 14399). Verified by Aaron M. Bauer. Loveridge (1947. Bull. Mus. Comp. Zool. 98:1–469) roughly outlines the distribution of *Hemidactylus longicephalus* as "Angola north to British Cameroons east to Lake Tanganyika" and mentions several specific localities in countries within this range, but not Equatorial Guinea. Although expected there, no voucher specimens of this species had been collected from Equatorial Guinea. This specimen represents the first record of this species for mainland Equatorial Guinea, and extends the confirmed range of this species from the nearest vouchered locality in Cameroon, ca. 250 km to NNE (Perret 1963. Rev. Suisse Zool. 70:47–60).

Submitted by **TWAN A.A.M. LEENDERS**, Division of Vertebrate Zoology, Yale Peabody Museum of Natural History, 170 Whitney Avenue, P.O. Box 208118, New Haven Connecticut 06520-8118, USA; e-mail: leendersa@sacredheart.edu.

MABUYA DORSIVITTATA. BRAZIL: SANTA CATARINA: FLORIANÓPOLIS MUNICIPALITY: Ilha de Santa Catarina: Restinga da Joaquina (27°35'36"S, 48°35'56"W). 10 December 2003. D. Vrcibradic, C. F. D. Rocha, V. A. Menezes, and C. V. Ariani. Museu Nacional, Rio de Janeiro (MNRJ 11117). Verified by R. Fernandes. This species has been reported from Argentina, Paraguay, Uruguay, Bolivia, and Brazil (Peters and Donoso-Barros 1970. Catalogue of the Neotropical Squamata. Part II. Lizards and Amphisbaenians. Bull U.S. Natl. Mus. 297:1–293; Cei 1993. Monogr. Mus. Reg. Sci. Nat. Torino 14:1–949; Lema 1994. Comunic. Mus. Ciênc. Tecnol. PUCRS, Sér. Zool. 7:41–150). In Brazil, it is known from Rio de Janeiro state to the south (Dunn 1935. Proc. Acad. Nat. Sci. Philadelphia 87:533–577), but there are few literature records giving precise Brazilian localities. These include records from the montane region of Itatiaia in Rio de Janeiro state and from a few localities in the states of São Paulo and Rio Grande do Sul (Dunn, *op. cit.*; Gallardo 1968. Rev. Mus. Argentino Cs. Nats., Zool. 9:177–196), one record from Castro, in Paraná state (Bérnils and Moura-Leite 1990. Arq. Biol. Tecnol. 33:469–480), and a few records from montane and inland localities in Rio Grande do Sul state (Lema, *op. cit.*). Ilha de Santa Catarina is a large continental island separated from the mainland by about 0.5 km at the closest point. This note provides the first insular record for the species and also the first vouchered record from the state of Santa Catarina.

Submitted by **DAVOR VRCIBRADIC, CARLOS FREDERICO D. ROCHA, VANDERLAINE AMARAL DE MENEZES,** and **CRISTINA VALENTE ARIANI,** Departamento de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, 20550-011, Rio de Janeiro, RJ, Brazil.

PHYLLOPEZUS PERIOSUS. BRAZIL: CEARÁ: NOVA JAGUARIBARA (05°35'26.3"S, 38°26'40.7"W). 19 March 2004. Museu de Zoologia da Universidade de São Paulo (MZUSP 93989). Adult specimen (SVL 10.26 cm, TL 11.2 cm) collected in fractured boulders. Verified by H. Zaher. Previously known only from semi-arid northeastern Brazil, in the states of Alagoas (Piranhas), Paraiba (Cabaceiras and Congo), Pernambuco (Sítio dos Nunes and Ibimirim), and Rio Grande do Norte (Serra Negra do Norte) (Rodrigues 1986. Pap. Avuls. Zool. 36[20]:237–250; Freire et al 2000. Herpetol. Rev. 31:54). First state record, extends the known distribution 175 km NW from the closest known locality in Serra Negra do Norte, state of Rio Grande do Norte (Freire et al., *op. cit.*),

Submitted by **IGOR JOVENTINO ROBERTO** and **PAULO THIERES PINTO DE BRITO**, Associação de Pesquisa e Preservação de Ecossitemas Aquáticos – AQUASIS. Rua Praia de Iparana, SESC Iparana, Iparana, 61600-000, Caucaia, Ceará, Brazil.

SERPENTES

AGKISTRODON CONTORTRIX (Copperhead). USA: TEXAS: FRANKLIN CO: 12.1 km SE Mount Vernon at Walleye Park on Lake Cypress Springs. 4 September 2004. M. L. Cameron. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28726). Verified by Stanley E. Trauth. New county record completely filling county distributional hiatus in east and eastcentral Texas (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 421 pp.; Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. Univ. of Texas Press, Austin, 437 pp.). Juvenile specimen collected within reported zone of intergradation of *A. c. contortrix* x *A. c. laticinctus* (Gloyd and Conant 1990. Snakes of the *Agkistrodon* complex. SSAR Contributions in Herpetology No. 6:1–614).

Submitted by **MICHELLE L. CAMERON, STEPHANIE F. BARCLAY,** and **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA; e-mail: chris.mcallister@tamut.edu.

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: TEXAS: LEE CO. / BURLESON CO.: Yegua Creek above Lake Summerville. Collected in March 2003. Natu-

ral History Museum, University of Kansas color slide (KU CT-11922). Verified by John E. Simmons. This specimen was collected in the middle of Yegua Creek. This species has not been recorded previously from Lee County (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 421 pp.). Yegua Creek represents the border between the two counties.

Submitted my **WILLIAM B. MONTGOMERY,** P.O. Box 656, Elgin, Texas 78621, USA; e-mail: montgomery6@earthlink.net.

BOTHRIOPSIS TAENIATA (Speckled Forest-pitviper). GUYANA: Mazaruni-Potaro District, Wokomung Massif, lat. 05°04'03.3" by long. 59°51'44.8", ca. 1135 m elev. 16 July 2003. Collected about 1 m off the ground in cloud forest vegetation by the David Clarke Smithsonian botanical expedition and given to D. Bruce Means. Two 35mm slides deposited in Florida Museum of Natural History Museum (UF-142004). Verified by William W. Lamar. First record of species in Guyana and extends range about 105 km E of closest previously known location in the saddle between Cerro Kukenan and Mt. Roraima, Estado Bolivar, Venezuela (Means 1994. South American Explorer 36:23–29; Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Vol. I. Cornell Univ. Press, Ithaca, New York). The record is notable because it fills a distributional gap between Suriname on the east and Venezuela on the west.

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute and Land Conservancy, 1313 Milton Street, Tallahassee, Florida 32303, USA.

ECHINANTHERA MELANOSTIGMA. BRAZIL: MINAS GERAIS: Municipality of Ouro Preto (20°23'S, 43°30'W, ca. 1159 m elev.), area of transition between Atlantic Forest and "Cerrado" biomes. Two specimens from Estação Ecológica do Tripuí collected 13 June 2000 by A. L. Silveira (Laboratório de Zoologia dos Vertebrados, Universidade Federal de Ouro Preto, Ouro Preto, Minas Gerais, Brazil; LZVUFOP 030 S) and Parque Estadual do Itacolomi collected in 1999 by A. S. Guimarães Neto (LZVUFOP 376 S). Verified by R. Fernandes (Museu Nacional / UFRJ, Rio de Janeiro). Previously known from southeastern Bahia, Rio de Janeiro and mid-east of São Paulo, Brazil, in Atlantic Forest near coastline (Di-Bernardo 1992. Comun. Mus. Ciênc. PUCRS, sér. zool. 5[13]:225–256). First state record, extends known distribution ca. 235 km NW from the previous closest record (Brazil, Rio de Janeiro, Teresópolis; IB 41042) (Di-Bernardo, *op. cit.*).

Submitted by **ADRIANO LIMA SILVEIRA**, Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional / Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil (e-mail: biosilveira@yahoo.com.br); **MARIA RITA SILVÉRIO PIRES,** Laboratório de Zoologia de Vertebrados, Instituto de Ciências Exatas e Biológicas, Universidade Federal de Ouro Preto, Campus Morro do Cruzeiro, CEP 35400-000, Ouro Preto, MG, Brazil (e-mail: mritasp@iceb.ufop.br); and **GISELLE AGOSTINI COTTA**, Serviço de Animais Peçonhentos, Fundação Ezequiel Dias, Rua Conde Pereira Carneiro, nº 80, Bairro Gameleira, CEP 30510-010, Belo Horizonte, MG, Brazil (e-mail: crotalus@funed.mg.gov.br).

ELAPHE PRASINA (Green Bush Rat Snake). THAILAND: TAK PROVINCE: Muang Tak District: 30 km SW of Tak; ca. 700 m asl. 1 August 2003. G. Vogel. Institut Royal des Sciences Naturelles de Belgique (IRSNB 16981). Verified by Georges Lenglet (IRSNB). Juvenile male (SVL 278 mm, tail L 98 mm) found dead on a small road at the edge of old secondary forest. First provincial record. The closest Thai records are situated ca. 230 km ENE in Loei Province (Schulz 1996. A Monograph of the Colubrid Snakes of the Genus *Elaphe* Fitzinger. Koeltz Scientific Books, Havlickuv Brod, iii + 439 pp.; Manthey and Grossmann 1997. Amphibien und Reptilien Südostasiens. Natur und Tier – Verlag, Münster, 512 pp.; Chan-ard et al. 1999. Amphibians and Reptiles of Peninsular Malaysia and Thailand. An Illustrated Checklist. Bushmaster Publications, Würselen, 240 pp.; Schulz and Grossmann 2000. Sauria 22[2]:31–36). Even including the present findings, records of *E. prasina* in Thailand are confined to the two northern provinces of Loei and Tak, although the species is broadly distributed outside the country, from eastern India to Peninsular Malaysia. We thank Tanya Chan-ard (National Science Museum, Pathumthani) for useful information.

ELAPHE VULPINA (Western Fox Snake). USA: WISCONSIN: CRAWFORD CO: Specimen found DOR at Lynxville. HDW-NIU 1937. Sect. 23, T9N, R6W. 25 May 2003. Alan Hagensick and Jeff Hughes. Verified by Julie Ray. New county record (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Interim Report Wisconsin Herpetological Project, Milwaukee Public Museum. 87 pp.), previously having been taken in adjacent Grant, Richland, and Vernon counties.

Submitted by **HARLAN D. WALLEY,** Department of Biology, Northern Illinois, Dekalb, Illinois 60115, USA (e-mail: hdw@niu.edu), and **JORDAN R. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA, and 640 East McKinley Street, Hinckley, Illinois 60520, USA.

ERYTHROLAMPRUS MIMUS MICRURUS (False Coral Snake). ECUADOR: PROVINCIA DE BOLÍVAR: San Luis de Pambil (79°14'W, 01°15'S, ca. 300 m). 21 February 1992. C. Cabrera. Universidad San Francisco de Quito and Fundación Herpetológica Orcés, Quito, Ecuador. (FHGO-USFQ 429). Verified by J. M. Touzet. *Erythrolamprus mimus micrurus* occurs from Panama to western Ecuador (Dunn and Bailey 1939. Bull. Mus. Comp. Zool. 86:12; Peters 1960. Bull. Mus. Comp. Zool. 122:9). First province record, extending distribution ca. 70 km S from nearest known locality in the province of Los Ríos (Perez-Santos and Moreno 1991. Serpientes de Ecuador. Monogr. XI. Mus. Reg. Scien. Nat. Torino. 540 pp.). The species was previously known in Ecuador from the provinces of Esmeraldas, Los Ríos. and Pichincha (Peters 1957. Amer. Mus. Novitates 1851; Peters 1960, *op. cit.*; Perez-Santos and Moreno, *op. cit.*; Kuch and Freire 2002. Herpetozoa 15[3/4]: 182).

Submitted by **DIEGO F. CISNEROS-HEREDIA**, College of Biological and Environmental Sciences, Universidad San Francisco

de Quito, Ave. Interoceánica y calle Diego de Robles, Campus Cumbayá, Edif. Maxwell, Casilla Postal 17-12-841, Quito, Ecuador; e-mail: diegofrancisco_cisneros@yahoo.com.

HYPSIGLENA TORQUATA (Nightsnake). USA: WASHINGTON: DOUGLAS Co: Moses Coulee/Palisades Rd., ca. 13.8 km NE of junction with State Route 28, elevation: ca. 306 m (UTM 11 277744 E 5251432N, 47°22.7'N, 119°56.6'W). DOR female (CWU 1678, 330 mm SVL, 14 g) collected 23 July 2004. Robert E. Weaver. Verified by David M. Darda. Some regional field guides depict the range of *Hypsiglena torquata* throughout Douglas County (Storm et al. 1995. Reptiles of Washington and Oregon, Seattle Audubon Society, Seattle. 176 pp.). However, this specimen represents the first record from within the county (Washington State Herp Atlas 2003. Washington Natural Heritage Program, Washington Dept. Fish and Wildlife, and USDI Bureau of Land Management [http:// www.dnr.wa.gov/nhp/refdesk/herp/] Nussbaum et al. 1983. Amphibians and Reptiles of The Pacific Northwest. Univ. Idaho Press, Moscow. 337 pp.).

Submitted by **ROBERT E. WEAVER**, Department of Biological Sciences, Central Washington University, 400 East University Way, Ellensburg Washington, 98926-7537, USA; e-mail: weaverr@cwu.edu.

LEPTOTYPHLOPS DIMIDIATUS. BRAZIL: MINAS GERAIS: Municipality of Ouro Preto (20°23'S, 43°30'W, ca. 1100 m elev.), Estação Ecológica do Tripuí, an area of transition between Atlantic Forest and "Cerrado" biomes. 1999. A. S. Guimarães Neto. Laboratório de Zoologia dos Vertebrados, Instituto de Ciências Exatas e Biológicas, Universidade Federal de Ouro Preto, MG, Brazil (LZVUFOP 372 S). Verified by R. Fernandes. Species known from Guyana, Suriname, southeastern Venezuela, and northern Brazil in the Rupununi Savanna and its extension, usually in only slightly elevated coastal areas (McDiarmid et al. 1999. Snake Species of the World: A Taxonomic and Geographic Reference, volume 1. The Herpetologists' League, Washington. 511 pp.). First record for the State of Minas Gerais, southeastern Brazil and the "Cerrado" biome, extending the known distribution southeast limit, ca. 3300 km of the previous record (type locality: Brazil, Roraima, São Marcos near confluence of the Rios Uriracuera and Tacatu, both tributaries of the Rio Branco) (Peters and Orejas-Miranda 1970. Catalogue of the Neotropical Squamata: Part I Snakes. U. S. Natl. Mus. Bull. 297:169).

Submitted by **ADRIANO LIMA SILVEIRA**, Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional / Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil (e-mail: biosilveira@yahoo.com.br); **MARIA RITA SILVÉRIO PIRES,** Laboratório de Zoologia de Vertebrados, Instituto de Ciências Exatas e Biológicas, Universidade Federal de Ouro Preto, Campus Morro do Cruzeiro, CEP 35400-000, Ouro Preto, MG, Brazil (e-mail: mritasp@iceb.ufop.br); and **GISELLE AGOSTINI COTTA**, Serviço de Animais Peçonhentos, Fundação Ezequiel Dias, Rua Conde Pereira Carneiro, nº 80, Bairro Gameleira, CEP 30510-010, Belo Horizonte, MG, Brazil (e-mail: crotalus@funed.mg.gov.br).

LEPTOTYPHLOPS SUNDEWALLI GESTRI (Sundevalls Worm Snake). CAMEROON: SOUTHWEST PROVINCE: Nyasoso (Mt Kupe): 4°49'85"N, 9°41'25"E, 910 m asl. In garden. 5 January 2003. Patricia A. Herrmann. Verified by Wolfgang Böhme. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 82153). Second record from Cameroon and northernmost locality by an extension of ca. 100 km. The first specimen (one of the type series of *Glauconia gestri*) was collected from Buea (Boulenger 1906. Ann. Mus. civ. Stor. Nat. Genova 2:196–216). Although the species has been mentioned for Cameroon by Perret (1961. Bull. Soc. Neuchateloise Sci. nat. 84:133–138) and Hughes (1983. Bonn. Zool. Beitr. 34:311–356), we were unable to trace any vouchers.

Submitted by **HANS-WERNER HERRMANN**, Center for Reproduction of Endangered Species (CRES), Zoological Society of San Diego, PO Box 120551, San Diego, California 92112-0551, USA (e-mail: hwherrmann@sandiegozoo.org), **PATRICIA A. HERRMANN**, Messa, Yaounde, Cameroon, and **VAN WALLACH**, Museum of Comparative Zoology, Harvard University, 26 Oxford Street, Cambridge, Massachusetts 02138, USA.

LIOTYPHLOPS ALBIROSTRIS. VENEZUELA: ZULIA: Municipio Insular Padilla, Isla de Toas (10°76'N, 72°40'W), 3 m. 1 December 1997. A. Rincón Rincón. Museo de Biología de La Universidad del Zulia, Maracaibo (MBLUZ-R-0736); Municipio Mara, Sierra de Perijá, Fundo "La Orchila" (10°48'N, 72°21'W), 200 m. 13 November 2003. Fernando Rojas-Runjaic. (MBLUZ-R-0768). Both verified by T. Barros Blanco. The range of this neotropical species includes southern Central America and northern South America (McDiarmid et al. 1999. Snake Species of the World: A Taxonomic and Geographic Reference, Volume I, The Herpetologists' League, Washington, DC, 511 pp.). Its distribution in Venezuela includes the Capital District, Vargas, and Miranda up to Mérida and Maracaibo states (Barros 1991. V Jornadas Científicas, Universidad del Zulia, Facultad Experimental de Ciencias, Resúmenes, 68 pp; Barros and Soler 1990. II Congreso Latinoamericano de Herpetología, Libro de Resúmenes, 114 pp.; Dixon and Kofron 1983. Amphibia-Reptilia 4:241–264; Lancini 1986. Serpientes de Venezuela [Armitano, Ed.], 262 pp.; Lancini and Kornacker 1986. Die Schlangen von Venezuela [Verlag Armitano, Eds.], 381 pp.; Markezich 2002. Herpetol. Rev. 33:69–74; Roze 1952. Mem. Soc. Cienc. Nat. La Salle 12[32]:143–158; Roze 1966. La Taxonomía y Zoogeografía de los Ofidios de Venezuela, Ed. Biblioteca, Caracas, 362 pp.). Previous records from Zulia State are from the Lagunillas and Maracaibo municipalities (Barros and Soler, *op. cit.*; Barros, *op. cit.*). This record extends the distribution ca. 90 km (airline) W and ca. 33 km (airline) N of the previous westernmost locality, and establishes the presence of the species in the Perijá Range and on Toas Island.

Herpetological Review, 2004, 35(4), 413–418.

New Records for Reptiles and Amphibians from Milne Bay Province, Papua New Guinea

FRED KRAUS
and
ALLEN ALLISON
Bernice P. Bishop Museum, 1525 Bernice Street
Honolulu, Hawaii 96817, USA
e-mail (FK): fkraus@hawaii.edu

The Milne Bay area and some of its adjacent islands were among the earliest parts of New Guinea to be collected for reptiles and amphibians, resulting in the descriptions of a variety of new species (Boulenger 1890, 1896, 1897, 1898a, b, 1903a, b; de Vis 1892). For the next several decades, this area was largely ignored by herpetologists until two of the American Museum of Natural History's Archbold expeditions visited Milne Bay Province for extended stays from March to November, 1953, and March, 1956 to January, 1957 (Brass 1956, 1959). These expeditions collected on Mt. Dayman, second highest peak on mainland Milne Bay Province, and on most of the major offshore islands of the province. Although trained herpetologists did not accompany either expedition, large numbers of new amphibian species were collected and later described by Zweifel (1956, 1958, 1962, 1963, 1972a, 2000). Since the Archbold expeditions, additional collecting in the province was conducted by James Menzies and some of these specimens were used in his taxonomic studies (Menzies 1987, 1993; Menzies and Tyler 1977; Menzies and Zug 1979; Menzies and Zweifel 1974; Tyler and Menzies 1971), but with little direct consideration of the herpetofaunal composition of the province per se. Lastly, fairly broad collections were made during the 1980s on some of the offshore islands by parties from the Australian Museum but have never been reported on.

Milne Bay Province, like many other districts in New Guinea, has a large number of regional endemics found nowhere else. Because of this regional endemism and a desire to survey previously unstudied locations in the province, from April, 2002 to March, 2003 we conducted a series of three expeditions to survey for reptiles and amphibians in the province. Our activities resulted in the discovery of a number of species of reptiles and amphibians new to science as well as significant range extensions for a large number of other species. We herein provide a summary of the noteworthy range extensions for known species and supplement those with important records from the previously unreported material in the Australian Museum for which we were able to verify species identification.

Acrochordus granulatus. NORMANBY ISLAND: Samoau, N end Sewa Bay, 9.9519°S, 150.9455°E, 10 m asl. 26 September 2002. F. Kraus. Bernice P. Bishop Museum (BPBM) 16510. First record for D'Entrecasteaux Islands (O'Shea 1996).

Austrochaperina palmipes. FERGUSSON ISLAND: E slope Oya Tabu, 9.4576°S, 150.7888°E, 960 m asl. 23–25 August 2002. F. Malesa and D. Salepuna. BPBM 16113-115; E slope Oya Tabu, 9.4606°S, 150.7769°E, 1400–1500 m asl. 27 August 2002. F. Malesa and D. Salepuna. BPBM 16116–118; E slope Oya Tabu,

9.4601°S, 150.7723°E, 1720 m asl. 29 August 2002. F. Malesa and D. Salepuna. BPBM 16119; S slope Oya Waka, 9.4562°S, 150.5596°E, 980 m asl. 15 September 2002. F. Kraus and F. Malesa. BPBM 16120. First records for island (Zweifel 2000).

Boiga irregularis. WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 22–28 January 2003. A. Allison and native collectors. BPBM 17863–866. First record for island (O'Shea 1996).

Callulops robusta. FERGUSSON ISLAND: summit of Oya Tabu, 9.4624°S, 150.7668°E, 1830 m asl. 29 August 2002. F. Kraus and D. Salepuna. Voice recording only. Also heard at summit of Oya Waka but neither captured nor recorded. First record for island (Zweifel 1972a).

Candoia paulsoni. AMPHLETT ISLANDS: S side Wagabu Is., 9.3374°S, 150.6885°E, 1 m asl. 23 May 2002. F. Kraus and D. Mitchell. BPBM 16511. First record for island group (Smith et al. 2001). EAST CAPE: Boiaboiawaga Island, 10.2110°S, 150.9044°E, 1 m asl. 25 May 2002. F. Kraus and D. Mitchell. BPBM 16512. First record for island (Smith et al. 2001).

Carlia eothen. KILLERTON ISLANDS: Gau Hi Lama Island, 10.3502°S, 150.6633°E, 1 m asl. 26 May 2002. F. Kraus and D. Mitchell. BPBM 15887. First record for island group (Zug 2004).

Copiula minor. CLOUDY MTS.: 10.5009°S, 150.2302°E, 800 m asl. BPBM 15665–673. First record for mainland New Guinea; previously known only from Goodenough Island (Menzies and Tyler 1977).

Copiula oxyrhina. FERGUSSON ISLAND: E slope Oya Tabu, 9.4555°S, 150.7857°E, 1100 m asl. 21 August 2002. F. Kraus and D. Salepuna. BPBM 16158–160; E slope Oya Tabu, 9.4604°S, 150.7846°E, 1330 m asl. 22 August 2002. F. Kraus and D. Salepuna. BPBM 16161; E slope Oya Tabu, 9.4576°S, 150.7888°E, 960 m asl. 25 August 2002. F. Kraus and D. Salepuna. BPBM 16162; S slope Oya Waka, 9.4562°S, 150.5596°E, 980 m asl. 9–16 September 2002. F. Kraus and F. Malesa. BPBM 16163–178. First records for D'Entrecasteaux islands (Menzies and Tyler 1977). WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 23–24 January 2003. A. Allison and native collectors. BPBM 18167–171; vic. Talpos River, 6.9 km N, 18.5 km W Guasopa, 9.1640°S, 152.7801°E, 100 m asl. 26 January 2003. A. Allison and native collectors. BPBM 18172–180. First records for island (Menzies and Tyler 1977).

Dendrelaphis calligastra. FERGUSSON ISLAND: Basima, 9.4683°S, 150.8315°E, 5 m asl. 3 September 2002. Native collector. BPBM 16524. First record for island (O'Shea 1996).

Dendrelaphis punctulatus. NORMANBY ISLAND: Saidowai, 9.9637°S, 150.9546°E, 5 m asl. 30 September 2002. F. Kraus. BPBM 16526; near S end Sewa Bay, 10.0380°S, 150.9817°E, 80 m asl. 26 January 2003. F. Kraus. BPBM 17245; near S end Sewa Bay, 10.0331°S, 150.9812°E, 40 m asl. 30 January 2003. K. Helgen and F. Francisco. BPBM 17246. First records for island (O'Shea 1996).

Emoia atrocostata. NORMANBY ISLAND: Guleguleu. 29 December 1988. P. German and L. Seri. Australian Museum (AMS) R-129748–753, 129773–774. First record for island (Brown 1991). *Emoia jakati*. NORMANBY ISLAND: Saidowai, 9.9637°S, 150.9546°E, 5 m asl. 30 September 2002. F. Kraus. BPBM 15957–962; Samoau, 9.9519°S, 150.9455°E, 5 m asl. 26 September 2002. F. Kraus. BPBM 15956; Sibonai, 10.1358°S, 150.9708°E, 40 m asl. 31 January 2003. F. Kraus, F. Francisco, and G. Shea. BPBM 16875–877. First records for island (Brown 1991).

Emoia longicauda. NORMANBY ISLAND: Sibonai, 10.1358°S, 150.9708°E, 40 m asl. 31 January 2003. F. Kraus, F. Francisco, and G. Shea. BPBM 16803. First record for island (Brown 1991).

Emoia obscura. FERGUSSON ISLAND: E slope Oya Tabu, 9.4524°S, 150.7970°E, 650 m asl. 31 August 2002. F. Kraus. BPBM 15963; S slope Oya Waka, 9.4632°S, 150.5576°E, 690 m asl. 9 September 2002. F. Kraus. BPBM 15964; S slope Oya Waka, 9.4562°S, 150.5596°E, 990 m asl. 14–15 September 2002. F. Kraus. BPBM 15965–966; Saibutu, 9.4692°S, 150.5471°E, 240 m asl. 19 September 2002. F. Kraus. BPBM 15967-971. NORMANBY ISLAND: Saidowai, 9.9637°S, 150.9546°E, 5 m asl. 2 October 2002. F. Kraus. BPBM 15978. CLOUDY MTS.: SW of Gadowalai, 10.4971°S, 150.2330°E, 715–770 m asl. 9-23 April 2002. F. Kraus and I. Bigilale. BPBM 15521–552. OWEN STANLEY MTS.: SE slope Mt. Pekopekowana, 10.2826°S, 150.1548°E, 590 m asl. 13 May 2002. F. Kraus and I. Bigilale. BPBM 15553–556; SE slope Mt. Pekopekowana, 10.2851°S, 150.1822°E, 330 m asl. 16 May 2002. F. Kraus and I. Bigilale. BPBM 15563–566; ca. 15 km E Alotau, 10.3136°S, 150.6222°E, 270 m asl. 22-23 September 2002. F. Kraus and B. Yawi. BPBM 15972–975. First records for each island and for SE extremity of mainland New Guinea (Brown 1991).

Emoia pallidiceps. NORMANBY ISLAND: E end Sewa Bay, 10.0330°S, 150.9771°E, 40 m asl. 28 September 2002. F. Kraus. BPBM 15982–983; near Saidowai, 9.9530°S, 150.9607°E, 40 m asl. 2 October 2002. F. Kraus and F. Malesa. BPBM 15984–987; Sibonai, 10.1358°S, 150.9708°E, 40 m asl. 31 January 2003. F. Kraus, F. Francisco, and G. Shea. BPBM 17197–200. First records for island (Brown 1991).

Emoia tetrataenia. NORMANBY ISLAND: S of Sewa Bay, 10.0394°S, 150.9814°E, 110 m asl. 26–30 January 2003. G. Shea and native collectors. BPBM 16712, 16714; 10.0331°S, 150.9840°E, 60 m asl. 30 January 2003. G. Shea and native collectors. BPBM 16713; 10.0331°S, 150.9812°E, 40 m asl. 30 January 2003. G. Shea and native collectors. BPBM 16715; Sibonai, 10.1358°S, 150.9708°E, 40 m asl. 31 January 2003. F. Kraus, F. Francisco, and G. Shea. BPBM 16716–717; Gwalalahuwa, near Guleguleu. 25 December 1988. P. German and L. Seri. AMS R-143500–502. First records for island (Brown 1991).

Gehyra mutilata. WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 27–29 January 2003. A. Allison and native collectors. BPBM 17708–711. First record for island (Bauer and Henle 1994).

Gehyra oceanica. AMPHLETT ISLANDS: S side Wagabu Is., 9.3374°S, 150.6885°E, 1 m asl. 23 May 2002. F. Kraus. BPBM 15833. First record for island group (Bauer and Henle 1994). FERGUSSON ISLAND: Basima, 9.4683°S, 150.8315°E, 5 m asl. 1 September 2002. F. Kraus. BPBM 15834. First record for island (Bauer and Henle 1994). WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 29 January 2003. A. Allison and native collectors. BPBM 17712–713. First record for island (Bauer

and Henle 1994).

Genyophryne thomsoni. WOODLARK ISLAND: vic. Talpos River, 6.9 km N, 18.5 km W Guasopa, 9.1640°S, 152.7801°E, 100 m asl. 26 January 2003. A. Allison and native collectors. BPBM 17780–791; Unapoi Homestead, W shore Suloga Harbor, 9.1983°S, 152.7317°E, 80 m asl. 30 January 2003. A. Allison and native collectors. BPBM 17793–796. First records for island (Zweifel 1971).

Hemidactylus frenatus. MISIMA ISLAND: Liak, 10.6607789S, 152.6854395E, 3 m asl. 11–20 January 2003. F. Kraus. BPBM 16830–833. WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 23 January–1 February 2003. J. Slapcinsky. BPBM 17715–725. First records for each island (Bauer and Henle 1994).

Hemiphyllodactylus typus. PINI RANGE: Duabo, 10.4184°S, 150.3068°E, 300 m asl. 30 April 2002. F. Kraus. BPBM 15442. First record for province and southeastern peninsula of New Guinea (Bauer and Henle 1994).

Hypsilurus papuensis. NORMANBY ISLAND: Near S end Sewa Bay along Koyakakapowa [=Wasasaia] River, 10.0516°S, 150.9717°E, 50–65 m asl. 28 January 2003. Native collectors. BPBM 17251. First record for island (de Vis 1892; de Rooij 1915).

Lamprolepis smaragdina. MISIMA ISLAND: Nulia River, Liak, 10.6607789°S, 152.6854395°E, 5 m asl. 15 January 2003. F. Kraus and B. Seta. BPBM 16858. NORMANBY ISLAND: Saidowai, 9.9637°S, 150.9546°E, 5 m asl. 30 September 2002. A. Toginitu. BPBM 15995. WOODLARK ISLAND: Guasopa. 10–11 August 1987. G. Mengden. AMS R-124833, 124863, 124888; Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 22–30 January 2003. A. Allison and native collectors. BPBM 17575–586. First records for each island (de Rooij 1915; Mys 1988).

Laticauda colubrina. WOODLARK ISLAND: Guasopa. 9–11 August 1987. G. Mengden and T. Flannery. AMS R-124861, 124893–894, 124901–903, 125271; vic. Guasopa, 9.2183°S, 152.944°E, 0–5 m asl. 23 January 2003. A. Allison. BPBM 17879. First records for island (O'Shea 1996).

Lechriodus aganaposis. AGAUN AREA: Munimum Village. 8 August 1992. P. German. AMS 137939. First record for province (Zweifel 1972b).

Lepidodactylus lugubris. AMPHLETT ISLANDS: S side Wagabu Island, 9.3374°S, 150.6885°E, 1 m asl. 23 May 2002. F. Kraus and D. Mitchell. BPBM 15835-839. KILLERTON ISLANDS: Gau Hi Lama Island, 10.3502°S, 150.6633°E, 1 m asl. 26 May 2002. F. Kraus and D. Mitchell. BPBM 15840. First records for each island group (Bauer and Henle 1994). WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 23–27 January 2003. J. Slapcinsky. BPBM 17727–731. First record for island (Bauer and Henle 1994).

Lepidodactylus novaeguineae. EAST CAPE: Boiaboiawaga Island, 10.2110°S, 150.9044°E, 1 m asl. 25 May 2002. F. Kraus and D. Mitchell. BPBM 15841–847. First record for province and range extension of ca. 450 km from nearest record in Morobe Province (Bauer and Henle 1994; Brown and Parker 1977).

Lipinia longiceps. WOODLARK ISLAND: Sinkwarai River, 9.195°S, 152.8867°E, 5 m asl. 1 February 2003. A. Allison. BPBM 17587. GAWA ISLAND: SW side of island, 8.9783°S, 151.9709°E, 40 m asl. 1 February 2003. A. Allison. BPBM 17588. First records for each island (Günther 2000).

Lipinia noctua. NORMANBY ISLAND: Wamula. 1 January 1989. S. Donnellan. AMS R-129775. First record for island (Mys 1988; Zweifel 1979).

Litoria arfakiana. MT. SIMPSON: Bunisi Village, 10.0171°S, 149.6002°E, 1420 m asl. 16-24 February 2003. F. Kraus and B. Uruwa. BPBM 17098, 17118–124; Uga River near Bunisi Village, 10.0045°S, 149.6020°E, 1000–1400 m asl. 22 February 2003. Native collectors. BPBM 17099–110; Uga River near Gasu Village, 9.9982°S, 149.61066°E, 940 m asl. 24 February 2003. B. Uruwa. BPBM 17112–116; Etakaba Creek near Bunisi Village, 10.0290°S, 149.5947°E, 1540 m asl. 26 February 2003. F. Kraus and B. Uruwa. BPBM 17125. First records for province (Menzies and Zweifel 1974).

Litoria modica. MT. SIMPSON: Etakaba Creek near Bunisi Village, 10.0290°S, 149.5947°E, 1540 m asl. 26–27 February 2003. F. Kraus and B. Uruwa. BPBM 17894–908. First record for province (Tyler 1968).

Litoria wollastoni. FERGUSSON ISLAND: E slope Oya Tabu, 9.4576°S, 150.7888°E, 960 m asl. 19–28 August 2002. F. Kraus, F. Malesa, and D. Salepuna. BPBM 16081–111. First record for island (Menzies 1975; Menzies and Zweifel 1974; Tyler 1968).

Lobulia elegans. MT. SIMPSON: Bunisi Village, 10.0171°S, 149.6002°E, 1420 m asl. 16 February 2003. Native collectors. BPBM 16761–764; N slope Mt. Simpson, 10.0364°S, 149.5749°E, 2480 m asl. 16–21 February 2003. F. Kraus, F. Malesa, B. Uruwa, and native collectors. BPBM 16765–770, 16774–777, 16780; summit of Mt. Simpson, 10.0362°S, 149.5677°E, 2880 m asl. 18–20 February 2003. F. Malesa and native collectors. BPBM 16771–773, 16778–779; 0.5 km S Bunisi Village, 10.0209°S, 149.5947°E, 1490 m asl. 23 February 2003. Native collectors. BPBM 16781–783; Siyomu Village, 10.0145°S, 149.5970°E, 1300 m asl. 23 February 2003. Native collectors. BPBM 16784–788. First records for province (Mys 1988).

Mantophryne lateralis. NORMANBY ISLAND: Wamula. 30 December 1988. P. German and L. Seri. AMS R-129881; also heard, but uncollected, by us near Sibonai. 28 September 2002. First record for offshore islands (Menzies 1975; Zweifel 1972a).

Morelia amethistina. FERGUSSON ISLAND: Basima, 9.4683°S, 150.8315°E, 5–40 m asl. 30 August 2002. Native collectors. BPBM 16521. First record for island (O'Shea 1996).

Nyctimystes kubori. MT. SIMPSON: Uga River near Bunisi Village, 10.0244°S, 149.5902°E, 1000–1400 m asl. 26–27 February 2003. F. Kraus and native collectors. BPBM 17990–18001. First record for province and range extension of ca. 420 km from nearest reported locality at Wau (Zweifel 1980).

Nyctimystes persimilis. MT. SIMPSON: Bunisi, 10.0171°S, 149.6002°E, 1420 m asl. 15–26 February 2003. F. Kraus, B. Uruwa, and native collectors. BPBM 17909–932; along Etakaba Creek, 10.0290°S, 149.5947°E, 1540 m asl. 26 February 2003. F. Kraus and B. Uruwa. BPBM 17933–936. Range extension of ca. 40 km from only prior report at Mt. Dayman (Zweifel 1958).

Nyctimystes trachydermis. MT. SIMPSON: N slope Mt. Simpson, 10.0389°S, 149.5765°E, 2480 m asl. 18–19 February 2003. F. Kraus, B. Uruwa, F. Malesa, and native collectors. BPBM 18181–198; 10.0316°S, 149.5767°E, 2170 m asl. 20 February 2003. Native collector. BPBM 18199; MT. WANIP: Kawaya Village, 9.8667°S, 149.3833°E, 1400 m asl. 12 August 1992. P. German. AMS 137976. First records for province and range extension of ca. 370 km (Zweifel 1983).

Oreophryne inornata. FERGUSSON ISLAND: E slope Oya Tabu, 9.4604°S, 150.7846°E, 1330 m asl. 22–26 August 2002. F. Kraus, F. Malesa, and D. Salepuna. BPBM 16217–239; E slope Oya Tabu, 9.4574°S, 150.7764°E, 1480 m asl. 26 August 2002. F. Malesa and D. Salepuna. BPBM 16240–241; E slope Oya Tabu, 9.4601°S, 150.7714°E, 1770 m asl. 29 August 2002. F. Kraus and D. Salepuna. BPBM 16245; summit Oya Tabu, 9.4624°S, 150.7668°E, 1830 m asl. 28 August 2002. F. Malesa and D. Salepuna. BPBM 16243; S slope Oya Waka, 9.4562°S, 150.5596°E, 980 m asl. 9–13 September 2002. F. Kraus and F. Malesa. BPBM 16249–256. First records for island; previously known only from Goodenough Island (Zweifel 1956).

Oreophryne insulana. FERGUSSON ISLAND: E slope Oya Tabu, 9.4601°S, 150.7723°E, 1720 m asl. 29 August 2002. F. Kraus and D. Salepuna. BPBM 16548–551; summit Oya Tabu, 9.4624°S, 150.7668°E, 1830 m asl. 28 August 2002. D. Salepuna. BPBM 16546–547. First records for island; previously known only from Goodenough Island (Zweifel 1956).

Oxydactyla crassa. MT. SIMPSON: N slope Mt. Simpson, 10.0364°S, 149.5749°E, 2480 m asl. 16-21 February 2003. F. Kraus, F. Malesa, B. Uruwa, J. Slapcinsky. BPBM 17060–067, 17071–073; summit Mt. Simpson, 10.0362°S, 149.5677°E, 2880 m asl. 20 February 2003. F. Malesa. BPBM 17070. Range extension of ca. 40 km from only prior report at Mt. Dayman (Zweifel 2000).

Prasinohaema flavipes. MT. SIMPSON: Bunisi Village, 10.0171°S, 149.6002°E, 1420 m asl. Native collector. 24 February 2003. BPBM 16736; near Bunisi Village, 10.0209°S, 149.5947°E, 1490 m asl. 26 February 2003. Native collector. BPBM 16737–738. First record for province and range extension of ca. 250 km from nearest prior locality (Mys 1988; Zweifel 1980).

Prasinohaema virens. NORMANBY ISLAND: S of Sewa Bay, 10.0331°S, 150.9812°E, 40 m asl. 30 January 2003. G. Shea and native collectors. BPBM 16857. WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 22–30 January 2003. A. Allison and native collectors. BPBM 17589–594. First records for each island (Mys 1988).

Ramphotyphlops braminus. TROBRIAND ISLANDS: Kiriwina. June 1970. Australian Museum collecting party. AMS R-86839–840. First record for province (O'Shea 1996).

Ramphotyphlops depressus. WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 22 January 2003. J. Slapcinsky. BPBM 17889. First record for island, separated by ca. 370 km of open water from nearest populations on Bougainville and New Britain (Wallach 1996a).

Rana papua. NORMANBY ISLAND: near Sibonai, S end Sewa Bay, 10.0330°S, 150.9771°E, 40 m asl. 28–30 September 2002. F. Kraus, F. Malesa, and F. Francisco. BPBM 16317–335. First record for province (Menzies 1987, 1992).

Rana supragrisea. FERGUSSON ISLAND: E slope Oya Tabu, 9.4555°S, 150.7857°E, 1100 m asl. 22–24 August 2002. F. Kraus, F. Malesa, and D. Salepuna. BPBM 16336; E slope Oya Tabu, 9.4576°S, 150.7888°E, 960 m asl. F. Kraus, F. Malesa, and D. Salepuna. BPBM 16337–351; S slope Oya Waka, 9.4562°S, 150.5596°E, 980 m asl. 9–16 September 2002. F. Kraus and F. Malesa. BPBM 16352-358. NORMANBY ISLAND: S of Sewa Bay, 10.0406°S, 150.9826°E, 120 m asl. 27–28 January 2003. F. Kraus and G. Shea. BPBM 17126-136; 10.0394°S, 150.9822°E, 110 m asl. 29–30 January 2003. F. Kraus and G. Shea. BPBM 17137–143. First records for offshore islands (Menzies 1987).

Sphenomorphus aignanus. NORMANBY ISLAND: along Wasasaia River, S of Sewa Bay, 10.0516°S, 150.9717°E, 50 m asl. 28 September 2002. F. Kraus, F. Malesa, and F. Francisco. BPBM 16432; Wamula. 29 December 1988. P. German and L. Seri. AMS R-129746–747; 1–3 January 1989. S. Donnellan. AMS R-129770–771, 129779, 129793; WOODLARK ISLAND: Guasopa. 10 August 1987. G. Mengden. AMS R-124870; Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 24 January 2003. A. Allison and native collectors. BPBM 17530; vic. Talpos River, 6.9 km N, 18.5 km W Guasopa, 9.1640°S, 152.7801°E, 100 m asl. 26 January 2003. A. Allison and native collectors. BPBM 17532–535; Sinkwarai River, 9.195°S, 152.8867°E, 5 m asl. 1 February 2003. A. Allison. BPBM 17536–537. First records for each island (Boulenger 1898b; de Rooij 1915).

Sphenomorphus forbesi. FERGUSSON ISLAND: S slope Oya Waka, 9.4562°S, 150.5596°E, 990 m asl. 12–16 September 2002. F. Kraus. BPBM 16001-005. NORMANBY ISLAND: Guleguleu. 23 December 1988. P. German and L. Seri. AMS R-129727. First records for each island (Greer 1973).

Sphenomorphus granulatus. FERGUSSON ISLAND: E slope Oya Tabu, 9.4508°S, 150.7990°E, 560 m asl. 17 August 2002. F. Kraus. BPBM 16007; E slope Oya Tabu, 9.4604°S, 150.7846°E, 1330 m asl. 23 August 2002. F. Kraus, F. Malesa, and D. Salepuna. BPBM 16008–009; E slope Oya Tabu, 9.4548°S, 150.8043°E, 220-250 m asl. F. Kraus and D. Salepuna. BPBM 16010; E slope Oya Tabu, 9.4519°S, 150.7987°E, 570 m asl. F. Kraus and D. Salepuna. BPBM 16011; S slope Oya Waka, 9.4562°S, 150.5596°E, 990 m asl. 10–16 September 2002. F. Kraus. BPBM 16014–015; S slope Oya Waka, 9.4611°S, 150.5573°E, 790 m asl. 9 September 2002. F. Kraus. BPBM 16012-013. NORMANBY ISLAND: NE end Sewa Bay, 9.9530°S, 150.9607°E, 10 m asl. 2 October 2002. F. Kraus. BPBM 16016; Guleguleu. AMS R-129785; Wamula. AMS R-129754, 129769, 129772, 129776–778. CLOUDY MTS.: along Upaelisafupi Stream, SW of Gadowalai, 10.4971°S, 150.2330°E, 715 m asl. 9-23 April 2002. F. Kraus and I. Bigilale. BPBM 15615–626; OWEN STANLEY MTS.: along Wailahabahaba Creek (trib. of Sagabada River), SE slope Mt. Pekopekowana, 10.2826°S, 150.1548°E, 590 m asl. 10 May 2002. F. Kraus and I. Bigilale. BPBM 15627–628. First records for province and range extensions of 370+ km from nearest reported localities (Mys 1988).

Sphenomorphus jobiensis. MISIMA ISLAND: Umuna mine site. 20 August 1987. G. Mengden. AMS R-125008. First record for island (Mys 1988).

Sphenomorphus minutus. FERGUSSON ISLAND: E slope Oya

Tabu, 9.4591°S, 150.7809°E, 1400 m asl. 23 August 2002. F. Kraus, F. Malesa, and D. Salepuna. BPBM 16031; E slope Oya Tabu, 9.4548°S, 150.8043°E, 220–250 m asl. 31 August 2002. F. Kraus and D. Salepuna. BPBM 16032-037; Bwedoa, 9.4518°S, 150.8099°E, 160 m asl. F. Kraus and D. Salepuna. BPBM 16038; S slope Oya Waka, 9.4611°S, 150.5573°E, 790 m asl. 9 September 2002. F. Kraus. BPBM 16039. MISIMA ISLAND: Ridge above Bwaga Bwaga, 10.6740°S, 152.6828°E, 440 m asl. 12–13 January 2003. F. Kraus, B. Seta, and native collectors. BPBM 16840–842. NORMANBY ISLAND: Samoau, 9.9519°S, 150.9455°E, 5 m asl. 26 September 2002. F. Kraus. BPBM 16040; near Saidowai, 9.9530°S, 150.9607°E, 10 m asl. 2 October 2002. F. Kraus. BPBM 16041; Guleguleu. 23 December 1988. P. German and L. Seri. AMS R-129729. CLOUDY MTS.: near Upaelisafupi Stream, SW of Gadowalai, 10.4971°S, 150.2330°E, 770 m asl. 16–24 April 2002. F. Kraus and I. Bigilale. BPBM 15655–659. First records for each island and confirms presence on adjacent mainland (Mys 1988).

Sphenomorphus nigrolineatus. CLOUDY MTS.: near Upaelisafupi Stream, SW of Gadowalai, 10.4957°S, 150.2356°E, 770 m asl. 21 April 2002. F. Kraus and I. Bigilale. BPBM 15660. OWEN STANLEY MTS: along Wailahababaha Creek (trib. of Sagabada River), SE slope Mt. Pekopekowana, 10.2826°S, 150.1548°E, 590 m asl. 11 May 2002. F. Kraus and I. Bigilale. BPBM 15661. First records for province and range extensions of ca. 300 km from nearest localities in Central Province (Greer and Parker 1974).

Sphenomorphus solomonis. FERGUSSON ISLAND: Basima, 9.4683°S, 150.8315°E, 5 m asl. 1–2 September 2002. F. Kraus. BPBM 16043–044; Bwedoa, 9.4518°S, 150.8099°E, 160 m asl. F. Kraus and D. Salepuna. BPBM 16042; Ulua, 9.4520°S, 150.8251°E, 5 m asl. 3 September 2002. F. Kraus. BPBM 16045; Awatoa River, between Basima and Ulua, 9.4601°S, 150.8306°E, 5 m asl. 3 September 2002. F. Kraus. BPBM 16046–048; S slope Oya Waka, 9.4562°S, 150.5596°E, 990 m asl. 13–17 September 2002. F. Kraus. BPBM 16049–051; Iamalele mission station, 9.5109°S, 150.5291°E. 18 September 2002. F. Kraus and F. Malesa. BPBM 16052. MISIMA ISLAND: Between Liak and Bagilina, 10.6608°S, 152.6804°E, 20 m asl. 20 January 2003. F. Kraus and native collectors. BPBM 16734–735; near Bwagaoia. 16 August 1987. G. Mengden. AMS R-124924. WOODLARK ISLAND: Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 24–29 January 2003. J. Slapcinsky. BPBM 17678–679. First records for each island (Greer and Parker 1974; Mys 1988).

Stegonotus cucullatus. TROBRIAND ISLANDS: Kiriwina. June 1970. Australian Museum collecting party. AMS R-86836. First record for island group (O'Shea 1996).

Tiliqua gigas. NORMANBY ISLAND No date. S. Donnellan. AMS R-129710. First record for island (Shea 2000).

Toxicocalamus loriae. CLOUDY MTS.: near Upaelisafupi Stream, SW of Gadowalai, 10.4971°S, 150.2330°E, 715 m asl. 22 April 2002. F. Kraus. BPBM 15771. FERGUSSON ISLAND: Basima, 9.4683°S, 150.8315°E, 0–10 m asl. 3 September 2002. Native collector. BPBM 16544; S slope Oya Waka, 9.4562°S, 150.5596°E, 980 m asl. 10 September 2002. P. Robert. BPBM 16545; MT. SIMPSON: Bunisi Village, 10.0171°S, 149.6002°E, 1420 m asl. 25–26 February 2003. Native collectors. BPBM 17989, 18166; 0.5 km S Bunisi Village, 10.0209°S, 149.5947°E, 1490 m asl. 26 February 2003. Native collector. BPBM 18164; Siyomu Village, 10.0145°S, 149.5970°E, 1300 m asl. 23–26 February 2003. Native collectors. BPBM 17987–988, 18165. First records from mainland portion of province and for Fergusson Island (McDowell 1969; O'Shea 1996).

Tropidonophis statisticus. OWEN STANLEYS: SE slope Mt. Pekopekowana, 10.2806°S, 150.1721°E, 500 m asl. 8 May 2002. F. Kraus. BPBM 15160. MT. SIMPSON: Bunisi Village, 10.0171°S, 149.6002°E, 1420 m asl. Native collectors. 16–28 February 2003. Native collectors. BPBM 17293, 17299–300; 0.5 km S Bunisi Village, 10.0209°S, 149.5947°E, 1490 m asl. 23 February 2003. Native collectors. BPBM 17294–295; Siyomu Village, 10.0145°S, 149.5970°E, 1300 m asl. 24–25 February 2003. Native collectors. BPBM 17296–298. First records for province, as reported presence on Goodenough Island (Malnate and Underwood 1988; O'Shea 1996) is a misidentification of an undescribed species.

Typhlops inornatus. MT. SIMPSON: Bunisi Village, 10.0171°S, 149.6002°E, 1420 m asl. 22 February 2003. Native collector. BPBM 17236; Siyomu Village, 10.0145°S, 149.5970°E, 1300 m asl. 23 February 2003. Native collector. BPBM 17237; Ikara Village, 9.9801°S, 149.6311°E, 800 m asl. 2 March 2003. Native collector. BPBM 17238. First records for province and range extension of ca. 160 km from nearest locality in Northern Province (McDowell 1974; Wallach 1996b).

Varanus indicus. NORMANBY ISLAND: Guleguleu. 23 December 1988. P. German and L. Seri. AMS R-129730. WOODLARK ISLAND: Guasopa. 9 August 1987. G. Mengden. AMS R-124815, 124841; Guasopa, 9.2233°S, 152.9433°E, 5 m asl. 30 January–1 February 2003. A. Allison and native collectors. BPBM 18220–221. First records for each island (de Rooij 1915).

Acknowledgments.—We thank G. Shea for providing or verifying identifications for most of the skinks; I. Bigilale, F. Francisco, F. Malesa, D. Salepuna, G. Shea, B. Uruwa, and a host of native collectors for field assistance; Aussiya, H. Korage, D. Libai, D. Mitchell, F. Malesa, P. Robert, B. Salepuna, B. Seta, A. Toginitu, and Conservation International for logistical field assistance; C. Kishinami and K. Igeta for specimen curation; A. Greer, R. Sadlier, and J. Vindum for facilitating access to their collections and loaning specimens; the PNG National Museum and Art Gallery for providing in-country collaborative assistance; and the PNG Department of Environment and Conservation, PNG National Research Institute, and Milne Bay Provincial Government for permission to work in Milne Bay Province. This research was supported by National Science Foundation grant DEB 0103794.

The creation of the Illinois Herpetological Database and its subsequent publication (Phillips et al. 1999) has allowed Illinois herpetologists to quickly and easily determine areas in the state that require additional surveying. As a result, numerous contributions focusing on new records in Illinois have recently appeared in *Herpetological Review*. These studies have focused on state (Petzing et al. 2002; Petzing et al. 2000), regional (Crawford and Meyer 2002, Markezich and Beckett 2001), and county (Giazzon 2002) levels. Following this trend, we herein report new amphibian and reptile records from Pulaski County, located at the southern tip of Illinois. Specimens were collected during fall 2002 and spring 2003. All specimens were verified by C. A. Phillips and deposited in the Illinois Natural History Survey (INHS) herpetological collection. County records were verified by consulting published distributions in Phillips et al. (1999) and the Illinois Herpetological Database maintained at the Illinois Natural History Survey. The database contains information on Illinois amphibian and reptile species compiled from 30 U.S. collections as well as unvouchered records from herpetologists and other reliable sources. County level distribution data can be accessed from this database on the web at the following URL:

http://www.inhs.uiuc.edu/cbd/herpdist/herp.html

Caudata

Ambystoma maculatum (Spotted Salamander). Pulaski Co.: 1.5 km NNW of Perks, in wooded wetland W of North Boundary Rd. (NAD 83 UTM Zone 16: N4132788m E314768m). 29 October 2002. A. R. Kuhns. INHS 18694. Adult found under rotting log.

Ambystoma opacum (Marbled Salamander). Pulaski Co.: Section 8 Woods Nature Preserve (NAD 83 UTM Zone 16: N4130604m E321351m) 28 September 2002. J. A. Crawford and A. R. Kuhns. INHS 18710. Adult male found under rotting log. *A. opacum* were also encountered on the same day 7.2 km E of this site (NAD 83 UTM Zone 16: N4129961m E328500m) and 6.9 km NW (NAD 83 UTM Zone 16: N4132788m E314768m) of this site in a wooded wetland northwest of Perks on 29 October 2002.

Ambystoma talpoideum (Mole Salamander). Pulaski Co.: 1.5 km NNW of Perks, in wooded wetland W of North Boundary Rd. (NAD 83 UTM Zone 16: N4132586m E314733m). 29 October 2002. A. R. Kuhns. INHS 18695. Adult found under natural wood cover.

Anura

Pseudacris crucifer (Spring Peeper). Pulaski Co.: 1.5 km NNW of Perks in wooded wetland W of North Boundary Rd. (NAD 83 UTM Zone 16: N4132580m E314740m) 12 March 2003. A. R. Kuhns and J. A. Crawford. INHS 18818. A large chorus of this species was calling. On the same evening we also collected this species from a chorus 4.5 km WSW of this site at an ephemeral pool along Big Creek (NAD 83 UTM Zone 16: N4130341m E310746m).

Pseudacris triseriata (Western Chorus Frog). Pulaski Co.: 1.5 km NNW of Perks, in wooded wetland W of North Boundary Rd. (NAD 83 UTM Zone 16: N4132839m E314773m). 29 October 2002. A. R. Kuhns. INHS 18998. One individual found on leaf litter. Large chorus heard on 12 March 2003 at this site. On the same evening we collected this species from a chorus 4.5 km WSW of this site at an ephemeral pool along Big Creek (NAD 83 UTM Zone 16: N4130341m E310746m).

Serpentes

Agkistrodon contortrix (Copperhead). Pulaski Co.: 3 km NE of Olmstead near Chestnut Hills Nature Preserve (NAD 83 UTM Zone 16: N4119101m E316914m). 27 September 2002. A. R. Kuhns and J. A. Crawford. INHS 18784. DOR adult male.

Coluber constrictor (Racer). Pulaski Co.: 4.4 km NE of Olmstead at N entrance to Olmstead Lock and Dam (NAD 83 UTM Zone 16: N4119800m E318049m). 28 September 2002. A. R. Kuhns and J. A. Crawford. INHS 18717. DOR juvenile. Additional individuals were observed DOR 4.5 km NNE (NAD 83 UTM Zone 16: N4123943m E319860m) on 1 May 2003 and 8.6 km NNE of this site (NAD 83 UTM Zone 16: N4126703m E323240m) on 29 June 2003.

Nerodia rhombifer (Diamond-backed Watersnake). Pulaski Co.: 2.9 km E of I-57 on Shawnee College Road (NAD 83 UTM Zone 16: N4127002m E311587m). 29 June 2003. A. R. Kuhns. INHS 19032. DOR. Two DOR individuals were found at this site with the first on 1 May 2003. Because of the poor condition of both specimens, only the head and neck of the second individual was vouchered.

Acknowledgments.—We thank Jim Waycuilis for approving activities at Section 8 Woods. John Petzing and Christopher Phillips provided access to historical records at the Illinois Natural History Survey and John Petzing assisted with specimen preparation and preservation. We thank Michael Dreslik and Mathys Meyer for critically reviewing this manuscript. This project was partially funded by an Illinois Wildlife Preservation Fund of the Illinois Department of Natural Resources, Division of Natural Heritage grant #03-036W (to ARK). Specimens were collected under Illinois Department of Natural Resources permit numbers A02. 0749 and A03.0749 and Illinois Nature Preserves Commission special use permit for Section 8 Woods Nature Preserve.

Perhaps, once in a generation a treatise in ophidology breaks new ground and sets the stage for remarkable advances in herpetology. The fascination with snakes which fuels such interest is universal among humankind, whether from fear or admiration. Most herpetologists are driven by that fascination to become scientists and to prove, often unconsciously through knowledge, their supremacy over these magnificent creatures of symbolic power. And yet that power is never diminished. The present volumes (hereafter VRWH) are an expansion and extensive revision of Campbell and Lamar's 1989 work, *The Venomous Reptiles of Latin America* (hereafter VRLA), form such a landmark in knowledge bringing to mind Boulenger's *Catalogue of Snakes in the British Museum* (1882–1896) and Klauber's *Rattlesnakes* (1956) in terms of the impact on our science.

Of dangerously venomous reptiles, aside from the two lizards treated in another catalogue, Boulenger recognized and described 61 venomous snake species for the Americas in 75 pages out of the 727 pages of his worldwide coverage. Klauber's work was more restricted in treating 30 species of rattlesnakes but in astonishing detail and breadth of coverage (1505 pp.) from morphology and biology to venoms and snakebite. Klauber's book also was enlivened by extensive quotations from his many correspondents. Compare these to the present work which consists of the detailed treatment of the two venomous lizards, one seasnake, 72 coral snakes, and 117 pitvipers , including 30 kinds of rattlesnakes. The VRWH is more comparable to Klauber's than Boulenger's work with its broader coverage of the biology, venoms, and phylogeny of the included species. Klauber's *Rattlesnakes* also consists of two volumes, has no color illustrations, only 10 distribution maps but has 52 black-and-white photographs of living snakes and 186 black-and-white figures. On average there are 50 pages for each species described in this book. The earlier Campbell and Lamar's VRLA is one volume of 437 printed pages with six color maps, 109 black-and-white distribution maps, 520 color plates, and 48 black-and-white figures. The text averages 30 pages per species. The VRWH is 959 pages in length with 8 color maps, 113 black-and-white distribution maps, 1500 color plates (1365 of reptiles) and 282 black-and-white figures. The text averages 50 pages per species.

Volume one of VRWH opens with material that introduces the reader to the two main sections of the book. A cogent justification is presented for the construction of dichotomous keys for these reptiles by political units or in the case of the United States and Canada by region. It is noteworthy that additional keys are provided for genera by family and all species by genus in the taxon accounts. This is followed by a statement on species concepts that recommends a conservative approach to recognizing diagnosable allopatric populations as distinct species. However, Campbell and Lamar regard the allopatric *Micrurus tener* as distinct from *M. fulvius*, partition *Crotalus durissus* (sensu lato) into three species, and retain binominals for two insular Brazilian pitvipers. Although subspecies are mapped and often discussed for many taxa in VRWH, the authors do not comment on the viability of this arguably passé approach for describing infraspecific variation and or their interpretation of its usage. A section provides an update of changes in taxonomy from the 1989 book that are followed in the VRWH and another an overview of material to be covered in the individual species accounts.

A major portion of this volume is formed by the Regional Accounts and Keys to Venomous Reptiles (pp. 11–91). The organization and coverage is similar to that of the 1989 opus, but now includes coverage for the United States and Canada. Eight new full-page color maps of physiography and vegetation are provided. Tables detailing the distribution of all species with reference to the maps are a valuable feature. This section has been enhanced by having some keys in both English and Spanish (United States and Canada, Colombia, Mexico, and Peru) or Portuguese (Brazil). It is not clear why this was not done for the other keys for Spanish-speaking countries in this section.

Taxon Accounts (pp. 95–616) make up the remainder of volume one (pp. 95–475) and around a third of volume two (pp. 477–616). Each of the major taxonomic groups, venomous lizards, the elapids, and pitvipers, are introduced in slightly different modes. Information for the Helodermatidae is contained in the coverage of the genus *Heloderma*. A brief section provides data on the elapids and a somewhat longer one on pitvipers. Individual generic accounts cover each genus. A key to genera in English and Spanish is provided in all cases and one in English, Spanish, and Portuguese for coral snake genera. The accounts include: synonomy, etymology, characteristics, and an extensive summary of natural history, especially activity and behavior, conservation, prey, venom, parasites, predators, reproduction, and longevity. Tables summarizing diagnostic features and/or variation in scalation and coloration are provided for most genera. This material is supported by line drawings of the skull of the least once species for most genera and usually by the illustration of the hemipenes of one or more species as well. In the case of coral snakes the natural history material for the three genera is combined into a single section but the other materials are contained in the individual generic accounts. Keys to the species in English and Spanish are included for all genera and also in Portuguese for *Leptomicrurus*, *Micrurus*, and *Bothrops*. Species accounts include: synonyms, lists of vernacular names, etymology, a detailed description, extensive coverage of distribution, habitats, comparisons to similar species, and remarks (usually relating to taxonomy and variation). Detailed black-and-white figures of color pattern and/or cephalic scalation supplement the descriptions of most taxa. Most figures are of very high quality, but some copied from other works and some photographs have poor differentiation. 1365 spectacular color photographs, most taken by the authors, illustrate every species and noteworthy variants. Distributions are shown for each species on newly constructed dot maps. Those for many species show the ranges of named subspecies. However, there is no consistency in treatment in the text. In some cases (e.g., *Crotalus lepidus*) there is a detailed discussion of subspecific features; in others (e.g., *Micrurus proximus*) none at all.

The depth of coverage in the generic and species accounts is extraordinary and supported by numerous references to the literature and the authors' own extensive field and laboratory experiences with these reptiles. Many open with a delightful, insightful, informative or dramatic quotation by an earlier author, often from the 18th or 19th century, on a particular taxon. The Remarks sections make particularly good reading as they explain some of the idiosyncracies of previous workers, shed light where only fog previously prevailed and are filled with pithy comments on the exigencies of herpetological research. The glorious coverage in the Taxon Accounts section would by itself rate VRNW as an all-time great! It deserves both a 10 for contents and 10 in style points too! But there is more to come! Completely new additions to Volume 2 are major sections on mimicry, evolutionary relationships, and two on reptile envenomations and their treatment.

E. D. Brodie IIII and E. D. Brodie, Jr. provide a conceptual overview of venomous snake mimicry (pp. 617–633) and suggest ways that its study may contribute to general mimicry theory. In addition to a summary of the current status of coral snakes mimicry, the less familiar but interesting topics of viper and acoustic mimicry and tail luring are explored. I was surprised that there was no reference to Savage and Slowinski's (1992) extensive review of the variety of color patterns in coral snakes (venomous or not). A paper by Greene and McDiarmid (2004) referenced throughout is not in the Literature Cited. The list of potential venomous coral snakes mimics (Table 53) should also include the genus *Coniophanes* (*C. lateritus* and *C. meridanus*). Additionally, *Elaphe* (see pls. 1090–91), *Leptodeira* (see pl. 1169), and *Phyllorhynchus* (see pl. 1242) could be listed both as potential coral snake and pitviper mimics. Illustrations of all mentioned snakes are included in a gallery of fine color photographs (plates 1024–1360).

R. L. Gutberlet, Jr. and M. B. Harvey author the chapter on phylogeny for this work (pp. 634–662). Phylograms for snake family relationships and relationships within the Elapidae are provided based on the most recent published analyses. Original phylograms for coral snake relationships, New World pitviper genera, and species within pitviper genera grace the chapter. Contrary to these authors, it seems likely that coral snakes were in North and South America from Paleocene on with sympatry between the two major clades only developing after the Isthmian Link was restored in Pliocene. That pitvipers did not reach South America until Pliocene seems confirmed by their analysis.

The chapter on venom poisoning in North America by R. Norris (pp. 683–708) covers venoms, their clinical features, field and hospital management, and morbidity and mortality. This chapter is a must have reference for clinicians in regions where highly venomous reptiles occur. Differences among species in venom characteristics and yields, especially for pitvipers are detailed as these are crucial factors in any treatment regimen.

A final chapter by D. Warrell (pp. 709–761) is an extensive review of snakebite occurrence, clinical features, and management for Central and South American venomous reptiles. A significant feature is an original review of 41 rear-fanged or mildly venomous colubrid snakes of the Americas known or suspected to be capable of human envenoming. Four species, *Phalotris lemniscatus*, *Philodryas olfersi*, *Tachymenis peruvianus*, and *Xenodon severus*, have been implicated in systemic and allegedly fatal bites. In several of these cases it is a small child that has died. Morrell states (p. 719) "it is questionable whether any colubrid snake can be regarded as definitely nonvenomous...." suggesting that there are toxic characteristics to oral secretions in most if not all species. Of course, the size of the snake, the nature of the saliva or venom, and the mass and physiology of the bite victim affects whether a bite is possible or will have a serious outcome. One has mixed feelings about the listing of so many snake species as possibly venomous. Certainly there is a need for some warning of possible harmful effects from bites by presumably inoffensive or mildly venomous snakes. However, one can see such a listing used to justify indiscriminate killings of harmless snakes by people who have an irrational fear of them. It is clear that some human individuals may exhibit allergic responses to the bite of a particular snake species while others will not. The great variation in saliva, venom, and human physiological sensitivity begs for focused research on supposed colubrid envenoming. The remainder of this chapter covers known envenomations by dangerously venomous American reptiles, species by species.

Treatment of victims and a thorough discussion of antivenom use and availability (Table 63) complete this section. The two chapters on snakebite are supported by a gallery of graphic and horrific color photographs (pls. 1366–1500) of snakebite injuries. These certainly should be enough to discourage beginning snakers from handling venomous reptiles. Although we all know it won't, at least it will encourage more caution.

In my review of the VRLA in 1990 I extolled the virtues of that marvelous contribution even then looking forward to a second expanded edition. The VRWH is much more than that! The breadth and depth of coverage, as illuminated by the authors' knowledge of these animals in life, makes it a truly phenomenal contribution. It is a must buy for all herpetologists. In addition, it is an essential reference for anyone interested in tropical biology and conservation, hobbyists, medical and veterinary clinicians, and field biologists. Every biology department library and every field station in the Americas should have a copy of these volumes on its shelves. To paraphrase my conclusion in my 1990 review: if you can afford only one book on venomous reptiles of the Americas buy this one! Better yet buy one for home and one for the field! Or even better, buy another and send it to a colleague in Mexico, Central or South America. To Campbell and Lamar this time around, I can only add c'est magnifique!

The Venomous Reptiles of the Western Hemisphere (*VRWH*) is an expanded and updated version of *The Venomous Reptiles of Latin America* (*VRLA*), also by Campbell and Lamar (1989). *VRWH* is expanded geographically to cover the United States and Canada and taxonomically to include five new species of venomous coralsnakes and nine new species of pitvipers described since *VRLA*. In addition, "11 novel species of coralsnakes and 19 species of pitvipers have been added to the valid species list owing to recognition of certain populations or taxonomic rearrangements" (p. xiii). Thus, *VRWH* contains several novel taxonomic arrangements (e.g., the splitting of the *Atropoides nummifer* and *Crotalus durissus* complexes into three species each; the transfer of the species *Sistrurus ravus* to *Crotalus*). Another change in *VRWH* from that of *VRLA* is the inclusion of dot locality maps for most species and the depiction of subspecies ranges for some species.

A preface (pp. xiii–xv), which also includes acknowledgments, precedes the Introduction (pp. 1–8). These short sections are followed by a section titled Regional Accounts and Keys to Venomous Reptiles (pp. 11–91). Color Plates 1–751 follow p. 91 and include the lizards of the genus *Heloderma*, the venomous coralsnakes, the sea snake *Pelamis platurus*, and the pitvipers, exclusive of the rattlesnakes. The Taxonomic Accounts begin on p. 95 and are arranged in the same sequence as are the color plates. An index of 28 pp. that covers both volumes closes out Vol. I. Color Plates 752–1365 covering the rattlesnakes and some snake species considered to mimic dangerously venomous snakes and/or to be slightly toxic themselves begin Vol. II. The Taxon Accounts for the rattlesnakes cover pp. 477–616. These accounts include the following sections for each species: synonymy, local name(s), English name, etymology, distribution, habitat, description, and similar species. A remarks section is also included for most species. Distribution maps of all species are included (most have dot locality symbols and overall perceived ranges indicated by shading), but as some maps include more than one species, a few maps are some page distance from their respective species account (i.e., the species account of *Crotalus triseriatus* is 66 pages from its map). Following the Taxon Accounts are four chapters written by contributors. These chapters are: 1) Venomous Snake Mimicry by Edmund D. Brodie III and Edmund D. Brodie Jr. (pp. 617–633); 2) The Evolution of New World Venomous Snakes by Ronald L. Gutberlet Jr. and Michael B. Harvey (pp. 634–682); 3) Venom Poisoning by North American Reptiles by Robert Norris (pp. 683–708); and 4) Snakebites in Central and South America: Epidemiology, Clinical Features, and Clinical Management by David A. Warrell (pp. 709–761). Color Plates 1366–1500 depicting consequences of reptile bites are nested between pp. 684–685 in the Norris chapter. The last of these four chapters is followed by a Glossary (pp. 763–773), the Literature Cited (pp. 775–870), and a repeat of the same index that closed out Vol. I.

Each of the four chapters written by the contributors is well researched, well written, and reflects the expertise of its author(s). The images depicting some of the consequences of snakebites will be troublesome to some of the users of these volumes, but should also serve as a reminder to the damage some of these venomous creatures are capable of inflicting.

The quality of the photographs making up the color plates is generally very good to excellent. These images were either taken by the authors themselves or obtained from numerous colleagues (these latter photographers are named in the respective Plate Legends) and Campbell and Lamar are to be commended for bringing together all of these photographs into one standard work. I could find only four minor critiques of the species photographs: 1) the

five images (Plates 1361–1365) of the highly venomous species following the last image of the mimics and/or slightly venomous species are out of place and seem to have been added as an afterthought; 2) the locality data "mainland opposite Los Cayos Cochinos, Atlántida, Honduras" accompanying Plates 66–67 are erroneous as *Micrurus diastema* does not occur in that part of Honduras (see next number); 3) the locality data "mainland opposite Los Cayos Cochinos, Atlántida, Honduras" accompanying Plate 138 are erroneous as *Micrurus nigrocinctus* from that area are bicolor (see Plate 142; the presence of an animal dealer at that locality in the 1980s probably reflects the source of these erroneous data); and 4) the specimen of *Sibon longifrenis* depicted in Plate 1290 cannot be a paratype as indicated.

Since I have examined much of the literature on, and many Honduran specimens of the 16 species of dangerously venomous snakes of the families Elapidae and Viperidae occurring in that country for a manuscript on the reptiles of Honduras, I took a hard look at those respective species accounts and the section on Honduras in the Regional Accounts.

The section on Honduras is slightly changed from that version in *VRLA*, but the statement (p. 38) "It is probable that *Micrurus alleni* occurs in extreme eastern Honduras" remains in *VRWH* even though McCranie (1993) reported that species from the country as noted elsewhere in *VRWH*. The Key to the Venomous Snakes of Honduras contains one notable error. The second part of couplet 1 should lead to couplet 7, not 6 as stated in *VRWH*. Because of that error in the Honduran key, I checked the keys for the other countries and found the following errors: Guatemala—the second part of couplet 1 should lead to couplet 10, not 9; Belize—the second part of couplet 3 should lead to couplet 4, not 5, the second part of couplet 4 should lead to couplet 5, not 6, and the second part of couplet 5 should lead to couplet 6, not 7; Panama—the second part of couplet 1 should lead to couplet 13, not 12, the second part of couplet 9 should lead to couplet 12, not 11, and the second part of couplet 18 should lead to couplet 19, not 18; Venezuela—the second part of couplet 3 should lead to couplet 10, not 9; Brazil—the second part of couplet 35 should lead to couplet 45, not 46 (also in the Portuguese version); Ecuador—the second part of couplet 26 should lead to couplet 27, not 26; Bolivia—the second part of couplet 1 should lead to couplet 10, not 11, the second part of couplet 2 should lead to couplet 9, not 10, and the second part of couplet 16 should lead to couplet 19, not 18; and Paraguay—the second part of couplet 8 should lead to couplet 13, not 14. Although these errors should be obvious to any user of the keys, they should have also been obvious to the authors and not allowed into print. Another curious aspect of the country keys is that a Spanish translation of the English keys was included for the Canada and United States key, but not for the keys to the seven Central American countries nor for the South American countries of Ecuador, Bolivia, Paraguay, Uruguay, and Argentina in which Spanish is the primary language.

With reference to the 16 species accounts critically read by me, I offer the following comments. The KU number for the specimen of *Micrurus* with conflicting identity is 214785, not 214784 (p. 154). Seven subspecies of *Micrurus diastema* are recognized in *VRWH* (see Plates 59–78, Map 9), but the statement (p. 163) "that recognition of these subspecies on any basis other than geographical distribution is difficult to justify" is odd and contrary to taxonomic principles. USNM 7347 is said to be the holotype of *M. nigrocinctus* (p. 179), but according to Cochran (1961) there are two syntypes under that number and Girard (1854) did not designate either of these as the holotype. BMNH 1946.1.21.20 is said to be the holotype of *M. ruatanus* (p. 191), but the describer (Günther, 1895) did not designate a holotype from among the eight specimens on which he based his description (these eight syntypes are BMNH 1946.1.21.16–22, MCZ 26930). The range of the ventral scales in male *M. ruatanus* is given as both 178–188 and 183–185 (p. 191). The presently valid combination *Pelamis platurus* is not given in that species synonymy (pp. 236–237). The first user of that combination was Stoliczka (1870). In reading the statement in brackets clarifying the type locality of *Bothriechis marchi* (p. 301), I had a feeling of déjà vu. That type locality was first clarified by Wilson and McCranie (1992) and the statement in *VRWH* is essentially identical to that in Wilson and McCranie (1992) without acknowledging the source. Although the publication in which the name *Trigonocephalus schlegelii* Berthold was first proposed has been well documented (Berthold, 1845; see Myers and Böhme, 1996) a later Berthold publication is cited as the original description (p. 304) in *VRWH*. Myers and Böhme (1996) also presented strong evidence clarifying the type locality of *Trigonocephalus schlegelii* Berthold of which the authors of *VRWH* were apparently unaware. The correct number of the holotype of *Trigonocephalus schlegelii* Berthold is ZFMK 32554 (see Böhme and Bischoff, 1984), not the number given in *VRWH*. MCZ 2718 is given as the holotype of *Trigonocephalus asper* Garman (p. 372), but Garman (1884) did not designate a holotype from among the specimens he used to draw up his description. Also, according to Barbour and Loveridge (1929), MCZ 2718 consists of two heads and Garman (1884) had at least one entire specimen that he used in his description. In the *Bothrops* key in *VRWH* (p. 358), the presence versus absence of dark spots or dark mottling on the supralabials was the sole character given to distinguish *B. asper* from the closely related *B. atrox*. But curiously enough, this character is not mentioned among the characters given in the similar species section for these two species that will distinguish them from one another. Also, the head drawing showing the color pattern in *B. atrox* (supposed to usually have at least two dark spots or dark mottling on the supralabials) does not show such spots or dark mottling (p. 377). Stuart (1963) is cited as the first use of the combination *Bothrops asper* (p. 372), but Stuart (1963) used the combination *B. atrox asper*. Three subspecies of *Crotalus simus* are recognized in *VRWH*, but no information is given on how to distinguish them from one another. On p. 584, the geographical distribution of *C. simus* is given as from "Mexico to Costa Rica," but on p. 586 it is said that the species occurs on "the Atlantic side of Colombia." Finally, Hoge and Romano Hoge (1983) used the presently valid combination *Porthidium ophryomegas* before Campbell and Lamar (1989) did.

One other notable error I found was that *Bothrops lanceolatus* Wagler, 1830, is given as the type species of the genus *Bothrops*. *Bothrops lanceolatus* cannot be the type species of *Bothrops* since it was not included in the nominal genus by Wagler (1824) (see Article 67 in the International Commission on Zoological Nomenclature, 1999). The correct type species of the genus *Bothrops* is *B. megaera* Wagler (1824) (= *B. lecurus* Wagler, 1824, by subsequent designation of Hoge, 1966).

VRWH is a long anticipated publication and despite my criticisms, wonderfully puts virtually everything known about these interesting and medically important creatures into one work. The authors' knowledge of the literature is impressive and comprehensive and speaks of a long time study and interest in these fascinating animals. I would highly recommend these two volumes to anyone with an interest in venomous reptiles in any part of the Western Hemisphere. However, given the number of errors detected in my sampling of *VRWH*, I recommend that serious users of these volumes consult the original literature if possible.

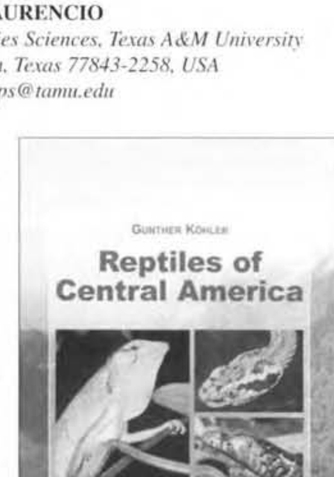
e-mail: norops@tamu.edu



Central America's reptile diversity has attracted scientists in ever-increasing numbers for many decades. Recently, a burgeoning eco-tourism industry and an increase in the popularity of reptiles have introduced the Central American herpetofauna to a new group of non-scientists. With interest in the region at an all time high, the need for guides to the area's species has led to several quality publications (Campbell 1998; Köhler 2001a; Lee 2000; McCraine and Wilson 2002; Savage 2002; Stafford and Meyer 2000). However, no English language guide exists covering the entire Central American region. With *Reptiles of Central America*, Köhler takes on the considerable task of filling this void.

The book is based upon Köhler's two-volume, German language *Reptilien und Amphibien Mittelamerikas* (2000, 2001b). It is not, however, merely a translation of the combined German volumes. Updated and expanded by 23 species, it now covers all three crocodilian, 25 turtle, 230 lizard, three amphisbaenian, and 276 snake species found in Central America. The author's stated goals for the book are to summarize widely scattered information on the reptiles of Central America, and "provide an identification guide for both scientists and travelers to the numerous reptile species found in Central America." To accomplish these goals, Köhler utilizes 644 color photographs, 103 drawings and diagrams, 210 maps and an extensive literature cited in this compact (17 x 23.5 cm), travel-friendly book.

The book can be divided into three parts: introductory sections, species accounts, and appendices. Introductory sections include the forward, introduction, comments on how to use the book, classification of reptiles, environment, and geographic history and zoogeography. These sections provide background for understanding the distribution and diversity of the Central American reptilian fauna. The forward by Larry David Wilson exalts the importance of herpetological research in Central America and points out the importance of this volume as a compilation of knowledge, as well as a springboard for future publications. A short, one and a half page introduction follows. It defines the region covered by the book as Mexico east of the Isthmus of Tehuantepec, south to the southern border of Panama. It then gives a brief history of herpetology in Central America and discusses the region's reptile

diversity. The introduction is followed by "comments on the usage of the book" (1.5 pages) where the author states the book's purpose, explains its layout, and suggests how to best utilize it. This section targets those unfamiliar with field guides and dichotomous keys, and introduces these topics well. Following the usage section, the author summarizes the classification of reptiles with a four page color-coded flow chart, which includes a list of the genera found in each family and the number of species in each genus. A representative photograph for every family (or subfamily) is included. The environment section (eight pages) points out the major geographical landmarks of the isthmus and describes its major habitats. Each habitat (sandy beaches, mangroves, dry forest, savanna, rain forest, cloud forest) is described and its distribution in the region is provided. At least one representative photograph illustrates each habitat type. The section continues with two full-page color maps depicting elevation and vegetational zones, followed by two pages devoted to climate in Central America. Climate data are summarized by a series of climographs, representing one locality in each country. The geographical history and zoogeography section (four pages), based primarily on Savage's work (1966, 1982, 2002), provides an excellent summary of the historical events that shaped present day reptilian fauna in Central America.

The bulk of the book (278 pages) consists of the species accounts, grouped by order or suborder (crocodilians, turtles, lizards, amphisbaenids and snakes). Each group is structured in a similar manner. After a brief description, a key to families is provided, followed by the family accounts, arranged alphabetically. Similarly, familiar accounts include a description, key to genera (if applicable) and generic accounts, again arranged alphabetically. Generic accounts contain a description, a key to species (where applicable), the species accounts and suggested further reading. The species accounts are shaded yellow and contain the scientific name, author, citation of original description and type locality, maximum size, and distribution of each species. When applicable, subspecies status is discussed. Ecological and reproductive data are presented in the generic descriptions, which range from half a page to 29 pages. Species photographs and range maps are included within the generic accounts, not in separate sections.

Three appendices follow the species accounts: a table of scalation characters in snakes, a section on snakebite, and one on mimicry in snakes. The table of scalation characters (six pages), includes the number of ventral and subcaudal scales, number of scale rows at mid-body and one head length anterior to the cloaca, as well as the state of dorsal scales (keeled/not keeled) and the cloacal scale (divided/undivided). The snakebite section (four pages) covers safety precautions and recommended first aid. It also includes a section on rear-fanged snakes and provides suggestions for further reading. This section is a great addition especially in light of the book's wide audience. A review of this section will benefit all who might come across venomous species. The section on mimicry in snakes (four pages) provides results of the latest research on mimicry, and includes 15 photographs of coral snake mimics. Suggestions for further reading on the topic are provided.

The book concludes with acknowledgements, an extensive 36-page literature cited, a glossary, and an index. The 119-term glossary (three pages) focuses on morphological terminology and references figures where terms are used. The seven-page index lists all species, genera and families found in the book but little else. Pages containing photographs are in bold; however, contrary to what the author states in the usage section, pages containing range maps are not italicized. The editing of the book is tight. I found only three typos (e.g., reptils for reptiles on page 12). The book's binding is of good quality and it has held up well to continuous use.

Köhler has clearly met the criteria he set for this book. First, he has compiled a wealth of widely scattered information, as evidenced by the 1087 citations. Most of this information is contained in the generic accounts and is supplemented by information from the author's extensive research. Second, he provides a good field guide to the reptiles of Central America. To accomplish this second goal, Köhler utilizes two of the book's greatest strengths, its photographs and dichotomous keys. The photographs, provided as the first method for identifying species, are of good quality, although a couple may be too small to be of use. Four hundred of the 537 species and all but three genera (*Atractus*, *Coloptychon*, *Diaphorolepis*) are pictured. In the case of the latter two genera, a line drawing is provided. Additionally, localities are given for all but a handfull of photographs. Of special note are the four pages devoted to photographs of anole dewlaps. Thirty-nine of the 81 species of anoles presented in the book have dewlap photographs.

The strength of the keys provided is that anyone, regardless of expertise, can successfully use them given minimal effort. Kohler explains dichotomous keys in the usage section and defines morphological terms that may be new to some readers in the glossary. Furthermore, the keys are supported by numerous figures. These visual representations of diagnostic characters greatly increase the ease of use. Additionally, many figures dealing with scalation characters are color-coded making them especially helpful. In reviewing this book, I worked through several of the keys (*Norops*, *Sphaeradactylus*, *Lepidoblepharis*, *Imantodes*, *Leptodeira*) with excellent results. That being said, keying out live individuals of small species in the field could prove difficult.

Good qualities notwithstanding, no book is without its drawbacks, however minor, and this volume is no exception. The range maps are small, contain multiple species (or genera), and due to the extent of the area covered, some tend to over-generalize distributions (e.g., *Crocodylus acutus* are not found in highland regions). Additionally, they contain no reference to museum specimens. The placement of range maps and photographs is sometimes awkward, in some instances appearing on a separate page with a different species account. Another point of contention is the author's quick acceptance of recently proposed taxonomic changes (e.g., *Aspidoscelis* for *Cnemidophorus* and *Mesoscincus* for *Eumeces*). Some may find these changes premature. Additionally, on at least one occasion, the author uses non-published data (a Master's Thesis) to make a taxonomic decision (the synonomy of *Norops oxylphus* with *N. lionotus*). While the data may indeed support the change, without peer review, its acceptance is questionable.

Nevertheless, these issues are, for the most part, minor and should not keep anyone from acquiring the book. *Reptiles of Central America* will make an excellent addition to the library of anyone, professional or amateur, interested in the reptiles in Central America. It delivers what it promises, and while the price (about $95) may seem steep to travelers with only a casual interest in

reptiles, the information contained within, and its ease of use make it well worth the price.

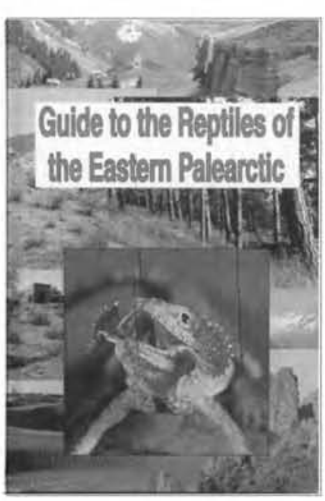
NATALIA B. ANANJEVA *and* **NIKOLAI ORLOV**
Zoological Institute, Russian Academy of Sciences
Universitetskaya emb., 1 St. Petersburg 199034, Russia



This long-awaited book is the first English language guide to the reptiles of the former Soviet Union (FSU). The fauna covered includes 161 species comprising five chelonians in three families, 93 lizards in seven families, and 63 snakes in six families. Some overview of the history of the book is necessary in order to place this review in context. The author, the well-known Ukrainian herpetologist Nikolai Szczerbak, died in 1998. The book, which was not complete at the time of his death, was prepared for publication by Mikhail Golubev, who is credited as technical editor. While the book was thus completed and translated into English, it was not updated, resulting in a work that reflects the nomenclatural and taxonomic status of the eastern Palearctic species as they stood nearly a decade ago. While this is not a fault of anyone in particular, and certainly not of the late author, it nonetheless detracts from the book.

The book opens with an editor's preface, providing an overview of Szczerbak's life and work and a short introduction dealing with biogeography and the basic geography of the former USSR. Szczerbak recognizes four main herpetogeographic divisions: the Arctic, Boreal European-Siberian, Himalayan-Manchurian, and Arid Mediterranean, each except the first with further subdivisions. Not surprisingly, the majority of species occupy the more temperate regions from the Caucasus to Middle Asia.

Identification keys are provided to families, genera, and to species in all non-monotypic groups. Unfortunately, the lack of accompanying labeled scale diagrams will prevent novice users from using the key effectively. Accounts are provided for all of the species of the FSU recognized through the mid-1990s except *Ablepharus darvazi* Panfilov and Jeriomtschenko, 1990, which is included in the key to species of the genus, but is not accorded its own account. The accounts, each one half to three pages in length, occupy the majority of the volume and include the standard subsections: Scientific name and author, Distribution (in the FSU and extralimitally), Natural History (including habitat, diet, seasonal activity, breeding, egg size, age at maturity, and maximum size), Status (including Red Data Book entries), References, and Remarks (often referring to the taxonomic status of subspecies or isolated populations). Accounts are accompanied by a distribution map with the range in the FSU shaded. The base map used shows major rivers, but not the boundaries of the countries of the FSU, which makes it rather difficult to use.

Three features promised in the "about the book" blurb on the back cover: type localities, discussion of ontogenetic, sexual and geographic variation, and point locality maps, are not actually provided. While these are not necessary components in such a guide, they would have made useful additions. We assume that the author had originally intended to include these features, but as they did not make it into the published version they certainly should not have been listed as selling points.

Major revisions have affected the taxonomy of many of the groups dealt with in the book. Some such changes are too recent to have been incorporated, even had the book been updated through 2002 or early 2003, and some changes have not yet been widely used or accepted. Nonetheless, users of Szczerbak's book will encounter discrepancies with the taxonomy employed in recent papers and it is worth noting at least some of these changes. Lizards assigned to *Lacerta* in the book include *L. vivipara* (p. 127), now often assigned to the genus *Zootoca*, and many species now assigned to *Darevskia* (Arribas 1999). Other lizard genera are in flux, and at least some authors employ different generic arrangements for *Eumeces* (e.g., Griffith et al. 2000; Schmitz et al. 2004) and for the Palearctic bent toed geckos *Mediodactylus* and *Tenuidactylus* (e.g., Khan 2003), and *Mabuya aurata* (p. 147) should now be assigned to *Trachylepis* following the recent subdivision of *Mabuya* (Mausfeld et al. 2002; Mausfeld and Schmitz 2003; Bauer 2003). As a representative of specific level issues,

Laudakia microlepis (given as a subspecies of *L. caucasica* [sic] in the book) has long been recognized as a distinct species (Ananjeva and Ataev 1984).

Even greater changes have taken place in the snakes. For example, the species of *Coluber* of the FSU are now assigned to *Platyceps*, *Hemorrhois* and *Hierophis* and some *Eirenis* have been removed to *Platyceps* as well (Schätti and Utiger 2001). The species of *Elaphe* treated in the book are now assigned to *Zamenis*, *Orthriophis* and *Oocatochus* (Utiger et al. 2002). Among vipers (divided into the Viperidae and Crotalidae by Szczerbak) *Vipera* (*Daboia*) *lebetina* is now *Macrovipera lebetina* (Hermann et al. 1992) and the *Agkistrodon* of the FSU are *Gloydius* (Hoge and Romano-Hoge 1981).

There are some minor spelling errors scattered throughout the book. For example: *Tachydromus* (p. 133) should be *Takydromus*, *Laudakia caucasica* should be *L. caucasia*, *Psammophis lineolatum* should be *P. lineolatus*, and *Ptyas mucosus* should be *P. muscosa* (David and Das 2004). Many accents and diacritical marks are missing from author's names or the names are incomplete, e.g. Lacepede (p. 190) instead of Lacepède, Menetrie (p. 137) or Menetries (pp. 169, 177) instead of Ménetries, Hallow (p. 144) instead of Hallowell, and Forskal (p. 142) and Forsskal (p. 205) instead of Forsskål. In a few places the date of authorship is incorrect: *Pelodiscus sinensis* Wiegmann, 1835 should be cited as *P. sinensis* (Wiegmann, 1834) (Bauer and Adler 2002) and *Coluber caspius* Gmelin, 1779 should be *C. caspius* Gmelin, 1789. The genus *Ablepharus*, attributed to Fitzinger in Lichtenstein, 1823 (p. 136), should be attributed to Fitzinger (1824) (Bauer et al. 2003). The 203 plates (194 in color) are arranged on 72 pages and include 10 views of representative habitats from Lithuania to the Russian far east, five chelonians, 119 lizards (36 agamids, 2 anguids, 2 eublepharids, 15 gekkonids, 52 lacertids, 11 skinks, and 1 varanid), and 69 snakes (4 boids, 46 colubrids, 6 crotalids, 1 elapid, 1 typhlopid, and 11 viperids). Many images are only fair in quality. Some suffer from color fading, others from extensive shadows, and some from poor focus or the use of unnatural backgrounds. Others, however, are quite good portraits, and virtually all are serviceable as aids to identifying the species depicted. Virtually all species are figured except *Ablepharus darvazi* and *Telescopus rhinopoma*.

The book concludes with a reference section of 203 entries. Naturally these include many works in Russian, although these are all presented with their titles translated into English. No references are later than 1996, highlighting the major problem with the currency of the book. On the other hand, the bibliography also lacks citations to most of the classic works of Russian herpetology; fewer than 10 references are older than 1960 and only one dates from the 19th century. In addition to many relevant Russian works of the last decade, also missing are the important references to adjacent regions that share components of the fauna of the FSU, for example Iran. Most of the citations included appear to be correct, although we noted several minor editorial errors including Schatti for Schätti, nouvean for nouveau, and a lack of capitalization of some German nouns in some titles.

Although those actually working in the region or dealing with the systematics of eastern Palearctic groups will certainly recognize that this book needs to be updated, it nonetheless fills an important gap in the literature that had previously existed. It will be the one basic reference that most English-speaking herpetologists will want to have in order to get an overview of the reptiles of the vast territory of the former USSR. Its keys will facilitate specimen identification and its bibliography will serve as an entrée into the extensive Russian herpetological literature, much of which will be unfamiliar to the intended audience. This posthumous work is a fitting cap to the body of published contributions of one of the leading herpetologists of the former USSR.

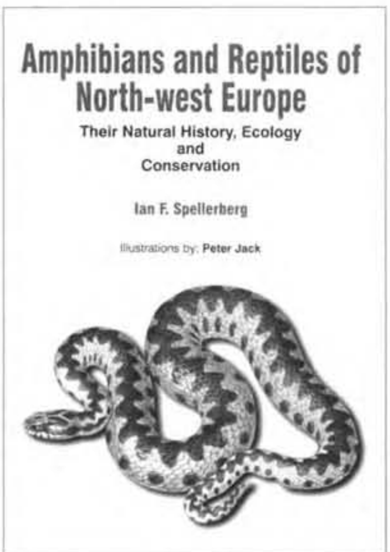
WOLFGANG BÖHME
Zoologisches Forschungsinstitut und Museum A. Koenig
Adenauerallee 160, D-53113 Bonn, Germany
e-mail: w.boehme.zfmk@uni-bonn.de



Ian Spellerberg adds another book to the rather long list of titles on European herpetology, but restricts it to the northwest of the continent and devotes it mainly to natural history and ecological and conservation issues. The geographic restriction is defined as the Atlantic Climatic Region which includes (according to figure 2 of the book) areas such as northeastern Germany, western Poland and even western Lithuania and Latvia, that are commonly considered to have a continental climate. The eastern borderline of this presumed Atlantic Climatic Region is indicated by a dashed line in each of the distribution maps of Spellerberg's book.

The introductory paragraphs deal with an overview of the current literature on the amphibians and reptiles of Europe, and they formulate the main aim of the book, viz. the promotion of conservation of the European herpetofauna. The selection of species (based on Spellerberg's own research interests in those taxa adapted to temperate and cold climates—hence the geographic region covered) and the structure of the species accounts is briefly explained. The next chapter is devoted to the ecology of amphibians and reptiles worldwide. Interestingly, "taxonomy and systematics" constitute a subchapter within ecology, thus shedding more light on the emphasis given by the author. The information contained in these introductory remarks is directed to readers without any preknowledge of zoology, explaining in a very simple way what a species is, what other systematic categories are, etc. Several misprints that would have been avoidable by careful proofreading, as well as some misleading statements, occur in this section. For example: (1) *Triturus cristatus* is said to have "poison glands on its back and tail," but the species for which this feature is most characteristic is certainly *Salamandra salamandra.* (2) It is stated that some quadrupedal lizard species may have lost one or both pairs of limbs, but "all retain at least traces of the pectoral girdle." It is obvious that this should read pelvic girdle. (3) "The lizards can re-grow another tail." This is generally true, but does not apply to *Anguis fragilis*, one of the species treated in the book. The sections that follow, on distribution and habitat, seasonal behavior, vagility and population ecology, feeding ecology, thermal ecology and reproduction, are better, underlining again the author's research interests and experience.

The main part of the book is the chapter containing species accounts. These accounts are subdivided following a uniform scheme. Species names (without author and year of description) appear under their respective family names, and a variety of European vernacular names are given (English, French, German, Dutch, Spanish, and Swedish). The single paragraph text sections are diveded into: introduction, taxonomy, protection, description, distribution and habitat, seasonal movements and behavior, vagility and population ecology, feeding ecology, thermal ecology, reproduction, growth and development, general comments, and major references. Each account is accompanied by a large, crudely-drawn distribution map with a roughly delimited range, and by a watercolor painting showing a typical specimen or, in the case of a sexual or ontogenetic dimorphism, a couple and a juvenile stage of the respective species. These paintings are generally well done, although in *Triturus cristatus* the male looks so slender that it resembles its relative *T. dobrogicus* (not an inhabitant of the Atlantic Climatic Region), and in *Rana dalmatina* the snout is much too blunt, resembling that of *R. temporaria*.

Unfortunately, the species accounts also contain a lot of misleading information and inconsistencies which cannot all be listed in this review. To give a few examples: The map for *T. helveticus* (p. 42) is far from being complete. Vast parts of the range are lacking on the map. For example, it reaches as far as the Czech Republic in the east (Günther 1996). In contrast, *Bombina variegata* (p. 56) is shown to be lacking in the Benelux and west German areas where it is actually common (Gasc et al. 1997). The section on *Hyla arborea* (p. 83) mentions the closely related *H. meridionalis,* but restricts it to North Africa, although it is the dominant species in the Iberian peninsula and in southern France. The Italian endemic species *Hyla intermedia* is not mentioned at all (see Dubois 1995). *Lacerta viridis* (p. 131) has been recognized as consisting of two species for the last 10 years (Günther 1996). The western European form is now called *Lacerta bilineata,* a form really adapted to Atlantic climatic conditions (Böhme 1978; Rykena 1991). The Greek generic name *Podarcis* does not mean "sure-footed" (p. 143), but swift-footed, quick, nimble (Böhme 1997, Arnold 2000). According to Spellerberg, *Coronella austriaca* (p. 149) was discovered in Britain by "a Mr. Gray." This formulation seems inappropriate for one of the historically most important British herpetologists.

On the other hand, there is information that seems peripheral to the stated aims of the book. Under the heading "General" in the *Alytes obstetricans* account, the reader is informed about the Austrian biologist Paul Kammerer and his experiments, the biography about him by Arthur Koestler, and the controversy that arose about Kammerer's theoretical background. And in another example, in the acount of *Lacerta* (now *Zootoca*) *vivipara*, we are informed that the author of the species, Baron Joseph von Jacquin, was "a friend of Mozart"!

The concluding chapter of this book is devoted to conservation. After a short treatment of turtles and tortoises (as a whole, regardless of their occurrence or absence in the Atlantic Climatic Region), Spellerberg provides an engaging overview of the different kinds of threats and of conservation needs and measures. Moreover, he offers some case studies focussed on Britain.

Although the author has compiled a list of interesting and important references, both for the general part of the book as well as for the single species accounts, the reference section looks a bit like a random compilation. Some of the references look as if they come from a first draft of a manuscript, such as that on p. 109 (*Rana ridibunda* account), where the initials of Mrs. Kyriakopoulou-Sklavounou are lacking, and have been substituted by "xx." There is no reference later than 1997, while the book was not published until five years after that date. Some references are only incompletely cited, including a major European reference edited by me, of which only the first of five volumes available up to 1999 is noted. Likewise, Spellerberg cites the first of the conservation-relevant monographs of the German Herpetological Society, on *Lacerta agilis* (Bischoff and Podloucky 1981), but not numbers 3 (on the snakes of Central Europe; Gruschwitz et al. 1993), 4 (on *Salamandra*; Greven and Thiesmeier 1994), 6 (on *Hyla arborea*; Geiger 1995), or 10 (on *Emys orbicularis*; Fritz et al. 1998), considering only those numbers published through 1999. German references are not the only ones lacking; important Scandinavian, Dutch, Belgian, and French sources are also missing, including the important *Atlas of Amphibians and Reptiles in Europe* (Gasc et al. 1997).

The book as a whole would have profitted much from more careful proofreading and from a different layout; much space was wasted and many pages could have been saved. Unfortunately, the question the author asked himself in the introductory section: "Why write another book about these animals...?" does not seem to have been convincingly answered.

PUBLICATIONS RECEIVED

Endangered and Threatened Animals of Florida and their Habitats, by Chris Scott. 2003. University of Texas Press, P.O. Box 7819, Austin, Texas 78713-7819, USA. xvi + 315 pp., 47 pp. pls. Softcover. US $29.95. ISBN 0-292-70529-8.

This book is divided into two main sections, a 100-page portion consisting of the chapters: Listed Species, Biological Pollution (invasive exotics), Saving Florida's Endangered Species, and Florida's Habitats, and a series of 63 species or subspecies accounts covering the threatened or endangered animals of the state. The first section highlights the great diversity of Floridian biota and the many threats faced by animals occurring in the state, as well as the measures in place to protect them. Black-and-white photographs in the four constituent chapters illustrate both habitats and animals, including native and invasive amphibians and reptiles. Reptiles constitute an especially significant component of the book. Accounts are provided for the two Floridian crocodilians and five sea turtles, as well as for one freshwater turtle, two skinks, and seven snakes. All but one of these (as well as two species not listed) are depicted in color in the section of plates that opens the books. Information provided for each species profiled includes state and federal status, description, distribution, biology, causes for decline and/or threat, and current trend (increasing, declining, or stable). Florida-specific threats, often at the geographic scale of counties, are emphasized and local data and case histories are summarized. The book concludes with a glossary, an extensive (14 pp.) bibliography, and a general index. This volume should be of interest to a broad audience of conservation biologists as well as professional zoologists and amateur naturalists who live in or visit Florida. It is available in hardcover as well ($60.00).

The Chameleons of Madagascar [DVD], produced by Ardith Abate and Edward Abate. 2004. Bella Natura Productions and The Chameleon Information Network (Chameleon Information Network, 13419 Appalachian Way, San Diego, California 92129-2601, USA; chamnet1@san.rr.com). US $19.95 + shipping and handling ($2.95 within the U.S.; California residents add $1.51 sales tax).

This 80-minute DVD includes footage of 28 Madagascan chameleon species of the genera *Furcifer*, *Calumma,* and *Brookesia* filmed in their natural habitats throughout Madagascar. In addition, a variety of other endemic Malagasy lizards, snakes, and frogs, as well as birds and mammals, are shown. These include leaf-tailed geckos, boas, and lemurs. The DVD is narrated on a stereo soundtrack. The film itself is accompanied by supplementary ma-

terial in the form of species profiles of each chameleon species including: scientific name, size, distinguishing characteristics, distribution, conservation status, and a still photograph. It should be of interest to those interested in the Afro-Malagasy herpetofauna from either an academic or conservation/law enforcement perspective, as well as to chameleon enthusiasts.

Mountains Kings: A Collective Natural History of California, Sonoran, Durango and Queretaro Mountain Kingsnakes, by Brian Hubbs. 2004. Tricolor Books, P.O. Box 24811, Tempe, Arizona 85285, USA; www.mountainkingsnake.com. Softcover. xxiii + 319 pp. US $45.00 (+ $5.00 postage for U.S. delivery; Arizona residents add $3.65 sales tax). ISBN 0-9754641-0-8.

This book is the first to present natural history information on the "mountain kingsnakes" of the western U.S. and parts of Mexico. The species included—*Lampropeltis zonata, L. pyromelana, L. mexicana* (part), and *L. ruthveni*—are probably not a natural grouping, but are treated together owing to their common association with montane or near-montane habitats as well as their popularity among herpetoculturists and hobbyists. The first two species are treated in great detail, a result of the author's considerable field experience with both, while the accounts for the species confined to Mexico are comparatively quite limited. Color and black-and-white photographs are included for all species and their habitats. Range maps indicating known and potential localities are provided; the maps for *L. zonata* and *L. pyromelana* are oversize foldouts. Sections on habitat damage, conservation laws, field searching tips, and captive care round out the book.

Artwork and Slides Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.

Also, we are interested in evaluating outstanding color slides of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any slides. We prefer to review images as JPEG or PDF files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.html>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information below) or from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Peabody Museum of Natural History, Yale University, P.O. Box 208118, New Haven, Connecticut 06520-8118, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Dr. Theodora Pinou, SSAR Treasurer, Western Connecticut State University, Department of Biological & Environmental Sciences, 181 White Street, Danbury, Connecticut 06810, USA. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

December 2004

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 35, Number 1 (March 2004).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **FREQUENCY OF ALBINO LIFE STAGES.** Complete albinos, partial albinos, and leucistic specimens have been observed among many species of North American amphibians and reptiles (Hensley 1959. Publ. Mus. Michigan St. Univ. 1. 159 pp.; Brame 1962. Abhandl. und Ber. für Naturk. und Vorgesch. 11:65–81; Drykacz 1981. SSAR Herpetol. Circ. 11. 31 pp.). However, there is limited information on the frequency of these uncommon phenotypes in natural populations. Although *Ambystoma opacum* is well-studied and abundant throughout the eastern United States, albino larvae have been reported in only three populations from Maryland, Mississippi, and Rhode Island (Drykacz, *op. cit.*; Deegan et al. 1998. Herpetol. Rev. 29:229; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C., 587 pp.). Here, we report on the frequency of albino salamanders among larval, metamorphic, and adult *A. opacum* from a population in southern Illinois.

On 9 March 2002 we discovered partial albino (*sensu* Brame, *op. cit.*) larvae while surveying an ephemeral pond in the Shawnee National Forest, Alexander County, Illinois (37°15'26"N; 89°21'36"W). Larvae typically have evenly dispersed stippling on the dorsal surface, speckled throats, and a distinct row of lateral light spots (Brandon 1961. Copeia 1961:377–383). These specimens appeared unusually pale due to a reduction in the intensity of pigmentation across the body; markedly reduced numbers of melanophores in the integument, and a faint indication of lateral spots. We measured two larvae (17.4, 18.1 mm SVL) and deposited them in the SIUC museum (SIUC-H07215). On 27 Sept 2002 we trapped one partial albino adult (67.6 mm SVL) while monitoring pitfall traps at a drift fence that completely encircled the pond. Adults are typically black in ground color with distinctive white to silver cross bands (Petranka, *op. cit.*). This gravid, female specimen appeared rosy-brown to pale tan in color and had normal retinal pigments; dull white cross bands were present. The salamander was photographed (SIUC-H07216) and released. Between 19 September and 10 October 2002 we trapped 184 male and 235 female *A. opacum* migrating to the pond, thus the partial albino phenotype occurred at a frequency of 0.24 in the breeding population. We captured one partial albino larva (22.1 mm SVL), similar in pigmentation to those described above, during quantitative sampling of the larval population on 9 June 2003. We estimated the size of the population on this day at ca. 4100 using a mean density of 331 larvae/m^3 (enclosure sampler, N = 8) thus the partial albino phenotype occurred at a frequency of ca. 0.024 in the larval population. All metamorphs trapped while emigrating from the pond in 2003 (N = 394) had typical amounts and patterns of pigmentation. Our report is the first to describe partial albino specimens of *A. opacum* in Illinois and provide data for comparing the frequency of this phenotype among populations and other amphibian species. We thank L. Woosley for her assistance in monitoring amphibians at this site.

Submitted by **LEE J. WALSTON**, Department of Biological Sciences, Eastern Illinois University, Charleston, Illinois 61920-3011, USA (e-mail: ljcwalston@yahoo.com), and **KURT J. REGESTER**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, USA.

CYNOPS PYRRHOGASTER (Japanese Fire-bellied Newt). **ENDOPARASITES.** *Cynops pyrrhogaster* is known from Honshu, Shikoku, and Kyushu Islands, Japan (Frost [ed.] 1985. Amphibian Species of the World: A Taxonomic and Geographical Reference. Allen Press, Inc. and The Association of Systematics Collections, Lawrence, Kansas, 732 pp.). Four species of Digenea, *Diplodiscus japonicus, Echinostoma hortense* (as metacercariae), *Mesocoelium brevicaecum, Phyllodistomum patellare*; three species of nematodes, *Amphibiocapillaria tritonispunctati, Gnathostoma spinigerum* (as larvae), *Rhabdias tokyoensis;* and one species of Acanthocephala, *Acanthocephalus nanus*, have been reported from *C. pyrrhogaster* (Uchida 1975. Bull. Azabu Vet. Coll. 30:63–81). In addition, *C. pyrrhogaster* has been experimentally infected with the nematode, *Spinitectus ranae* (Hasegawa and Otsuru 1977. Jap. J. Parasitol. 26:336–344). The purpose of this note is to report an additional species of Nematoda, *Cosmocercoides tridens,* from *C. pyrrhogaster.*

Twenty-four *C. pyrrhogaster* (mean SVL = 51.5 mm ± 4.5 SD; range 44–61 mm) were collected in Kanagawa and Shizuoka Prefectures, Honshu Island, Japan. Specimens were deposited in the herpetology collection of the Natural History Museum of Los Angeles County, Los Angeles, California as LACM 141230–141238, 143235–143237, 143265–143269, 144331–144336, 146590. The esophagus, stomach, small and large intestines, and lungs were opened and separately examined for helminths under a dissecting microscope. The body cavity was also examined for helminths. One species of Nematoda, *Cosmocercoides tridens*, was found in the small and large intestines. Both LACM 141234 and 143265 were infected. Prevalence (infected salamanders/salamanders examined x 100) was 8%. Mean intensity ± 1 SD (mean number of nematodes/number infected salamanders) was 2.0 ± 1.4 SD, range 1–3. Voucher nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as USNPC 93532.

Cosmocercoides tridens is known from *Cynops ensicauda* and *Echinotriton andersoni* from Okinawa, Japan (Hasegawa 1988. Can. J. Zool. 67:1189–1193). *Cynops pyrrhogaster* represents a new host record for *C. tridens.* Mainland Japan is a new locality record.

Tatsuo Ishihara, Hakoné Woodland Museum, Hakoné, Kanagawa Prefecture, provided the specimens for this study.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu).

NEURERGUS STRAUCHII (Anatolia Newt). **ENDOPARASITES.** *Neurergus strauchii* occurs in Turkey, Iran, and Iraq. In Turkey it occurs in east Anatolia (Baran and Atatur 1998. Turkish

Herpetofauna [Amphibians and Reptiles]. Republic of Turkey, Ministry of Environment, Ankara, 214 pp.). We know of no parasites reported from this salamander. The purpose of this note is to report the nematode *Cosmocerca commutata* in *N. strauchii.*

Nineteen *N. strauchii* (SVL = 154.6 mm ± 17.6 SD, range: 130–182 mm) were collected in Bitlis, Turkey (38°19'N, 42°05'E) during 2000–2002. Twenty two *N. strauchii* (SVL = 152.9 mm ± 11.9 SD, range: 130–171 mm) were collected in Malatya, Turkey (38°14'N, 38°37'E) during 2001. The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The infection site was the small and large intestines. Prevalence (infected salamanders/sample examined x 100) were: Bitlis (65%), Malatya (86%); mean intensity ± SD and range were: Bitlis 3.9 ± 3.0 SD, range 1–9; Malatya 10.9 ± 6.6 SD, range 1–23. Mean number of helminths was significantly higher at Malatya than at Bitlis, $t = 3.5$, $df = 30$, two tailed P value = 0.001. Selected nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as USNPC 93984. Voucher salamander specimens were deposited at Uludag University, Department of Biology.

Cosmocerca commutata is widely distributed in Palearctic anurans as well as the salamanders *Salamandra atra, S. salamandra*, and *Triturus cristatus* (Skrjabin et al. 1961. Oxyurata of Animals and Man, Part 2, Izdatel'stvo Akademii Nauk SSSR, Moskva. 460 pp.). *Cosmocerca commutata* in *N. strauchii* is a new host record.

Submitted by **HIKMET S. YILDIRIMHAN**, Uludag University, Science and Literature Faculty, Department of Biology, 16059 Bursa, Turkey (e-mail: yhikmet@uludag.edu.tr); **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu); and **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu).

PLETHODON CINEREUS (Red-backed Salamander). **ANOPHTHALMIA**. Abnormalities and malformations of limbs and eyes of amphibians are well documented in anurans (Ouellet et al. 1997. J. Wildl. Diseases 33:94–104; Meteyer 2000. Field Guide to Malformations of Frogs and Toads with Radiographic Interpretations. Biol. Sci. Rept., USGS/BRD/BSR-2000-0005, Madison, Wisconsin; Meteyer et al. 2000. Teratology 62:151–171). Deformities are known to occur on limbs and tails in the terrestrial salamander genus *Plethodon* (Wake and Dresner 1967. J. Morphol. 122:265–306) but abnormalities of the eyes have not been described for any plethodontid salamander, including *Plethodon cinereus* (J. Hanken, pers. comm.).

On 5 April 2002 an adult male lead-back phase *P. cinereus* missing its right eye was found by H. Germaine and M. Kangas in a sample of 35 under 22 pairs of coverboards in the Turkey Run Park section of the George Washington Memorial Parkway National Park (GWMP, Fairfax Co., Virginia). The habitat was hardwood forest dominated by oaks (*Quercus* sp.). The orbit was covered entirely with normally pigmented skin and did not appear injured, scarred, or unusual except for the missing eye. The abnormality appears to be congenital. Two other adult males each missing one eye were observed on 30 June and 4 July 2002 by E. Lanham in a sample of 400 studied at Mountain Lake Biological Station, Giles Co., Virginia. Like the one found in Fairfax County, the orbit on each was covered with normally pigmented skin suggesting a congenital defect. All of the salamanders appeared healthy. The GWMP specimen was lost following refrigerator mishap; the salamanders at Mt. Lake were released. Single cases of *P. cinereus* missing an eye (May 2001, Page Co., Virginia and July 2001, Fairfield Co., Ohio) are listed on the North American Reporting Center for Amphibian Malformations website (http://www.npwrc.usgs.gov/narcam/), although no descriptive information is available. Our observations are the first published records of anophthalmia in *P. cinereus* and the family Plethodontidae.

Submitted by **JOSEPH C. MITCHELL**, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA (jmitchel@richmond.edu), **ELVIRA LANHAM**, 5750 Trefalgar Park, Richmond, Virginia, 23228, USA (Present address: PO Box 64, Manly 1655, NSW, Australia), **MELISSA KANGAS, HEATHER GERMAINE**, National Park Service, c/o Turkey Run Park, George Washington Memorial Parkway, McLean, Virginia, 22101, USA, and **WILL BROWN**, 978 Bull Yearling Road, Stanardsville, Virginia, 22973, USA.

PLETHODON DUNNI, P. VEHICULUM (Dunn's Salamander, Western Red-backed Salamander). **BEHAVIOR**. Many amphibians that inhabit desert environments with a marked warm season display specialized behavior, morphology, or physiology that allow survival in hot dry conditions (Seymour and Lee 1974. Austral. Zool. 18:53–65; McClanahan et al. 1976. Copeia 1976:197–185; van Beurden 1980. Copeia 1980:787–799; Loveridge and Withers 1981. Physiol. Zool. 54:203–214). In contrast, amphibians that live in wetter environments often use mesic subterranean or woody debris refuges to evade seasonally brief drier or warmer conditions (Dumas 1956. Ecology 37:484–495; Hagar et al. 1995. *In* Beschta et al. [eds.], Cumulative Effects of Forest Practices in Oregon: Literature and Synthesis. Chapter 9, pp. 1–150. Oregon Dept. of Forestry, Salem, Oregon, USA.), and generally lack distinctive behavior to cope with unusually hot dry conditions. For this reason, we describe immersion and stream-use by *Plethodon dunni* and *P. vehiculum*, two terrestrial salamanders characteristic of the more pluvial North American Pacific Northwest, under drought and high temperature conditions.

During 29 July–5 August 2003, AEM and EPU made these observations while conducting amphibian surveys of 2nd-order stream reaches (*sensu* Strahler 1952. Bull. Geol. Soc. Amer. 63:1117–1142) of two non-fish bearing streams (A and B) in the Stillman Creek Basin, southwestern Washington State (Stream A: 46°31'28–35"N, 123°13'12–43"W; elev. 226–366 m; Stream B: 46°31'39–46"N, 123°13'17–14"W; elev. 238–390 m). Forests around the survey stream consisted of managed second growth stands of Douglas-fir (*Pseudotsuga menziesii*) over 40 years old. During surveys, two people moved upstream searching across the wetted width overturning moveable surface objects to enhance species detection. Before the first survey date on these streams, <12 mm of precipitation had fallen over the previous 10 weeks; the 2003 summer season was the driest in recorded history for Washington State (http://www.climate.washington.edu/details.html). Regional high air temperatures on the initial survey day were ≥ 34°C. Over

the 280 m of Stream A surveyed on that date, at least 20 *P. dunni* and 4 *P. vehiculum* were encountered, over 60% of which were found entirely immersed in the 160 m watered section of stream channel. Examination of both banks just centimeters above the wetted channel revealed it to be extraordinarily dry, both above and beneath surface objects. Furthermore, the water content of conifer needle litter and small organic debris on the substrate seemed very low, as it was brittle underfoot. Maximum daytime temperatures during the next four days (30 July, 4–6 August) when surveys were conducted in both streams were 3–5°C lower than on 29 July. Surveys over the next 660 m of Stream A on 30 July and 1660 m of Stream B on 4–6 August revealed 62 *P. dunni* and 46 *P. vehiculum* within a combined ca. 1900 m of watered channel length; no more than two of these were observed over the 450 m length of unwatered channel. In contrast to the individuals observed on the warmest survey date, 6.5% (N = 4) of the *P. dunni* and 7.1% (N = 3) of the *P. vehiculum* were immersed on the combined remaining survey dates, but all remaining non-immersed salamanders were encountered on moist or wet substrates within the hydrological influence of each of the two stream channels.

Although their hydration requirements differ somewhat (Dumas, *op. cit.*), *P. dunni* and *P. vehiculum* both exhibit greater near-surface activity under moist substrate conditions (Dumas, *op. cit.*; Peacock and Nussbaum 1973. J. Herpetol. 7:215–224; Ovaska and Gregory 1989. Herpetologica 45:133–143; unpubl. data). Furthermore, exposure to 32°C for < 20 minutes appear to be lethal to both species and stress becomes evident at 28–32°C (Dumas, *op. cit.*). Given this context, two aspects of our observations are notable. First, appearance of both species almost exclusively within the wetted channel margins implies that streambanks, a habitat both species often use (Dumas, *op. cit.*), became too dry to remain there. Second, salamanders being found predominantly in water only on the warmest day implies that air temperatures were high enough to make immersion in the stream channel a critically important refuge. More tolerable temperatures on subsequent days eliminated the importance of the water refuge. Both species are capable of swimming and surviving for some time in water (Dumas, *op. cit.*) and *P. dunni* in particular can be found in ponded or running water margins (unpubl. data), although observations suggest that both species typically avoid total immersion (Dumas, *op. cit.*). These observations suggest that even mesic-adapted plethodontids have an ability to respond to selected dry and warm condition extremes when suitable subterranean refuges may be unavailable. Greater attention needs to be given to understanding the range of such responses in view of global warming trends.

Anthony Melchiors facilitated permission to survey on Weyerhaeuser lands as part of the Amphibian Research Program of Forest and Fish Adaptive Management in Washington State. The Science Division of the Habitat Program of the Washington Department of Fish and Wildlife supported this research.

RHYACOTRITON CASCADAE (Cascade Torrent Salamander). **NEST**. On 14 Aug 2003, I discovered a nest of *Rhyacotriton cascadae* in a 2nd-order headwater stream on the west slope of the Cascade Mountains in Skamania County, Washington, USA (45°41'6"N, 122°1'48"W; elev. 740 m). The stream did not contain fish, but did support Tailed Frogs (*Ascaphus truei*) and giant salamanders (*Dicamptodon* spp.) A clutch of 5 eggs was found under a cobble-sized (14 x 15 x 5 cm) rock in the thalweg of a glide 10 cm deep x 60 cm wide x 72 cm long. The nest was located 473 m downstream of the flowing origin. Stream discharge immediately above the nest, measured by establishing a weir and recording fill time of a known volume, was 96 cm^3/sec and water temperature (at 0915 h) was 12°C. Eggs were neither attached to the substrate or each other; the current swept them away when I overturned the rock concealing them, precluding precise measurement. However, I was able to see that the ova were white, ca. 3–4 mm in diameter, and with ca.1-mm layer of clear jelly. The nest was unattended, but an adult female *R. cascadae* (46.3 mm SVL, 3.0 g, not visibly gravid) was captured 8 m upstream. The stream reach where the nest was located had a southerly aspect, 10% gradient, and bisected a power line right-of-way cleared of trees. However, vegetation cover over the nest site was 100%, multilayered, and made up of vine maple (*Acer circinatum*), salmonberry (*Rubus spectabilis*), and green alder (*Alnus sinuata*). The stream above the right-of-way to the origin was within a 30–121 m wide buffer (total width) within a 2–3 year old Douglas-fir (*Pseudotsuga menziessi*)-Noble Fir (*Abies procera)* plantation.

To date, the eggs of *R. cascadae* had not been found and oviposition in habitats similar to that of other *Rhyacotrotion*, i.e., in springs and seeps in deep cracks and crevices, may have been assumed (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest, Univ. Idaho Press, Moscow, 332 pp.; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC, 587 pp.). However, more recent information suggests that *R. variegatus* (Karraker 1999. Herpetol. Review 30:160–161) and *R. kezeri* (Russell et al. 2002. Northwest. Nat. 83:19–22) also oviposit in mid-channel under boulders and logs, well below the stream origin. Given the relatively few nest descriptions, understanding of habitat variation over which oviposition occurs undoubtedly is far from complete.

The number of eggs in the nest I found was less than that reported for other *Rhyacotriton* clutches (7–75; Nussbaum 1969. Herpetologica 25:277–278, Karraker, *op. cit.*; Russell, *op. cit.*), but within the range of mature ovarian eggs found in *R. cascadae* (Nussbaum and Tait 1977. Amer. Midl. Nat. 98:176–199).

Submitted by **JAMES G. MacCRACKEN**, Timber Department, Longview Fibre Company, 300 Fibre Way, Longview, Washington 98632, USA; e-mail: jmac@longfibre.com.

TARICHA GRANULOSA (Roughskin Newt). **FEEDING**. Roughskin Newts are predatory during both larval (Leonard et al. 1993. Seattle Audubon Society, Seattle, Washington. 56 pp.) and adult life stages (Chandler 1918. Oregon Agric. College Exp. Stat. Bull. 152:1–24; Efford and Tsumura 1973. Trans. Amer. Fish. Soc. 1:33–47; Evenden 1948. Copeia 1948:219–220). Adult Roughskin Newt predation on vertebrates has been recorded, but heretofore

prey taxa have been limited to the eggs and larvae of selected amphibians (Chandler, *op. cit.*; Efford and Tsumura, *op. cit.*; Evenden, *op. cit.*), all of which have limited evasive abilities when faced with a predator. By comparison, generally more elusive fishes are largely unrecorded as prey except among salamander taxa with aquatic life stages that engage in ambush predation and/or successfully co-occur with fishes. Here, we add *T. granulosa* to the list of salamanders known to consume fish, and describe their opportunistic predation on injured, disoriented fish.

On 2 July 2001, while performing amphibian surveys on the South Santiam River 6 mi E of Sweet Home (Linn Co., Oregon), CJR encountered a mixed-species school of ca. 200 small fish (ca. 30–60 mm fork length [FL]) in a seasonally isolated bedrock pool at the river edge. The pool, 1.5 x 2.0 m with a maximum depth of 7 cm, had ca. 3 cm of silt over its bottom, was surrounded by sedges (*Carex* sp.) 0.5 m high, and was connected to the river through a 70-cm wide channel that opened into a larger pool before reaching the river. Juvenile Northern Pikeminnow (*Ptychocheilus oregonensis*), adult Speckled Dace (*Rhinichthys osculus*), and Redside Shiner (*Richardsonius balteatus*) were the three dominant fish species in the pool; no newts were initially seen. After making one scoop through the school, CJR withdrew ca. 60 fish with a dipnet; they were examined briefly for identification. About 5 seconds after taking the sweep, 6 adult (65–85 mm SVL) *T. granulosa* emerged from among the sedge stems on the pool margin. During the sweep, a ca. 40 mm FL Speckled Dace that had been injured dropped into the water in front of an 85 mm SVL newt. This newt approached the fish and examined it briefly before engulfing it headfirst. Subsequently, CJR noticed 12 other fish in mid-pool (representing each of the three species observed) that the sweep had disoriented or incapacitated; all six newts converged on the fish and ate them. Observer presence did not appear to deter the feeding newts. Positioning of prey during ingestion appeared undirected; some fish were eaten headfirst, whereas others were grasped by the tail or at mid-body. On three occasions, a newt bit a fish protruding from the mouth of another newt and attempted to pull it away; all such attempts were unsuccessful. On one occasion, one newt grasped the leg of another newt and attempted to ingest it. The entire episode lasted ca. 10 min, during which time all compromised fish were eaten. Individual fish were completely ingested within ca. 45 sec. During the episode, five additional newts appeared in the pool connecting this one to the river, and approached the pool in which the feeding was taking place. After all compromised fish were eaten, both the newcomers and the feeding newts continued to search the pool. During this search, a 65 mm SVL newt lunged upward and captured an apparently healthy ca. 40 mm FL Redside Shiner from a passing school; the newt made one complete vertical revolution in the water and swallowed the fish in two gulps.

Fish consumption among salamanders can be grouped into those genera where it is more important (*Amphiuma, Cryptobranchus, Necturus*) versus less important (*Dicamptodon, Siren*). For all these genera, prey detection outside of the immediate visual field is probably based on olfaction (Green 1933. Proc. West Virginia Acad. Sci. 7:28–30; Green 1935. Proc. West Virginia Acad. Sci. 9:36; Harris 1959. Field Lab. 27:105–111; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC, 587 pp.; Smith 1907. Biol. Bull. 13:5–39). Our observations suggest that *T. granulosa* fits the less important grouping and that rapid recognition of compromised prey likely involved a non-visual modality as no *T. granulosa* appeared to be within visual range of the fish when they were injured. Furthermore, the five newts that approached the pool after feeding began did so from downstream, suggesting the presence of current-transported olfactory cues. As injured fishes, especially cyprinids, are known to release chemical compounds attractive to predators (Mathis et al. 1995. Amer. Nat. 145:994–1005; Wisenden 2002. J. Chem. Ecol. 28:433–438), the *T. granulosa* we described may have recognized and been attracted by such a cue (Neish 1970. A comparative analysis of the feeding behavior of two salamander populations in Marion Lake, B.C. PhD Diss., Univ. British Columbia, Vancouver. 108 pp.). Available data imply that *T. granulosa* consumes mostly small, slow-moving prey (Chandler, *op. cit.*; Evenden, *op. cit.*; Efford and Tsumura, *op. cit.*) but represent generalist predators that will eat almost any prey they can capture (White 1977. Northwest Sci. 51:114–118). We expect that Roughskin Newts rarely take fish due to the relative size and swiftness of such prey; however, our observations document the ability of Roughskin Newts to capture and consume fish when opportunities arise.

ANURA

ALSODES GARGOLA (Rana del Catedral). **OVERWINTERING TADPOLES**. Overwintering is a strategy that tadpoles seldom utilize. So far, the majority of the few published observations have come from the Northern Hemisphere (Bradford 1983. Ecology 64:1171–1183; Brown 1990. J. Zool. 220:171–184; Fellers et al. 2001. Herpetol. Rev. 32:156–157). Here, we report overwintering tadpoles for a South American species, *Alsodes gargola*, an endemic leptodactylid frog from the North Patagonian Andes of Argentina that has successfully colonized alpine environments.

At the end and at the beginning of three consecutive austral winters, as well as during the growing seasons in-between (2000–2003), we systematically surveyed two alpine lakes (Toncek, 1750 m and Schmoll, 1950 m elev.; 41°12'S, 71°30'W) along with the surrounding streams and shallow (depth < 1.5 m) pools. These water bodies are located within the Nahuel Huapi National Park (Río Negro Province, Argentina) and remain superficially frozen for 7–8 mo. per year.

At the end of each winter (December), just when the thawing period was starting, we observed several *A. gargola* tadpoles (ca. 5–20 per visit to the study site) through openings in the ice cap in the shallow (< 1 m) littoral zone of both lakes. These individuals were either hiding among the bottom rocks or swimming near the ice cap. Moreover, in slow current sections of streams and at the bottom of pools, some tadpoles (ca. 5–10) were observed through ruptures in the ice cap. All tadpoles observed during this period appeared in good physical condition.

During each growing season (January–April) many individuals (ca. 50–100 per visit) were seen in different sections of the shoreline of both lakes as well as at the bottom of pools and streams.

Many tadpoles were observed metamorphosing at the middle of the growing seasons. Judging from the size of the cohorts at the time, these were at least one year old.

At the beginning of each winter (May), when all the water bodies were already superficially frozen, we observed several tadpoles (ca. 10–25 per visit) along the shore of both lakes. They were either swimming just below the ice cap or hiding among the bottom rocks. Several individuals (ca. 5–15) were also found, under the ice cap, in the streams and pools.

Throughout the visits, tadpoles were normally found aggregated (ca. 2–20 individuals) in what seemed the most favorable microhabitats. These aggregations included individuals belonging to up to three cohorts (i.e., each cohort hatched in different summers) with total body lengths ranging between 20–90 mm (stages 32–38; Gosner 1960. Herpetologica 16:183–190). At the beginning and at the end of each winter, tadpoles were found in water at 0.1–3.0°C. Despite these low temperatures, they were usually active and, when inactive, they responded rapidly to mechanical stimuli. In conclusion, tadpoles of *A. gargola* overwinter (at least once) for 7–8 mo. in ice-covered alpine lakes, pools, and streams in the northern Patagonian Andes. During this period individuals do not enter a dormant state. Moreover, they seemingly do not experience high levels of winter mortality. The strategy of *A. gargola* tadpoles involves gaining as much biomass as possible by exploiting at least one complete growing season and thus metamorphose, at the middle of a certain summer, as bigger juveniles with higher probabilities to survive the approaching long winter.

AMOLOPS VIRIDIMACULATUS (Dahaoping Sucker Frog) **ARBOREAL ACTIVITY**. Frogs of the genus *Amolops* generally are reported from torrent streams. Adults usually are found at night on rocks at the sides of or in the middle of streams, or on wet vertical surfaces of waterfalls. During the day they have been found in rock crevices and low dense vegetation within the splash zone of the stream (Fei 1999. Atlas of Amphibians of China. Publishing House for Scientific and Technical Literature, Hunan, China. 432 pp.; Inger et al. 1990. Field. Zool. 58:1–24; Inger et al. 1999. Field. Zool. 92:1–46; Schleich and Kästle 2002. Amphibians and Reptiles of Nepal. A.R.G. Gantner Verlag Kommanditgesellschaft, FL 9491 Ruggell. 1201 pp.). Studies have shown that the expanded toe tips of *Amolops* are optimized for this type of wet surface habitat (Ohler 1995. Asiatic Herp. Res. 6:85–96). To date, no adult individuals of this genus have been reported from a high perch in vegetation outside of the splash zone. On 14 March 2002 at 2019 h during a light rain, an adult male *Amolops viridimaculatus* (76.9 mm SVL; California Academy of Sciences CAS 224378) was found at a height of 3.5 m on a bamboo plant above a stream. The animal jumped from one branch to another before diving into the stream. The *Amolops* was collected in Myanmar, Kachin State near Ngar Ngar village 27°49'55.9"N, 97°45'49.5"E (WGS 84) at an elevation of 1176 m in evergreen forest.

BUFO BOREAS BOREAS (Boreal Toad). **SCATS AND BEHAVIOR**. Adult Boreal Toads are known to engage in movements which sometimes are extensive (Carpenter 1954. Copeia 1954:197–200; Pimentel 1955. Herpetologica 11:72; Muths 2003. Copeia 2003:161–165), but the basis of movements is often unclear (Pimentel, *op. cit.*). Scattered data also indicate that *B. b. boreas* often eats ants, but identification of ant prey beyond a family level typically is not provided (Schonberger 1945. Copeia 1945:120–121; Campbell 1970. J. Herpetol. 4:83–85; Miller 1978. Northwest Sci. 52:243–239). Here, we report on the carpenter ant-filled scats of boreal toads from the Sky Lakes Wilderness in the Cascade Mountains of southern Oregon (USA), link their deposition to toad movements, and show their utility in revealing adult toad habitat use.

Observations were made during June–September in the Sky Lakes Basin (42°33'–42°38'N, 122°10'–122°14'W), a high-elevation (> 1700 m) plateau with > 200 lakes and ponds (0.01–9.62 ha in size) within a subalpine forest (Franklin and Dyrness 1973. Natural Vegetation of Oregon and Washington. USDA Forest Service, Portland, Oregon, General Technical Report PNW-8.) of mostly *Abies lasiocarpa*, *Pinus contorta*, and *Tsuga mertensiana*. In 1994, we conducted two visual encounter surveys (VES) between 0900 and 1700 h on 65 of these lakes and ponds with 2–3 surveyors via a slow perimeter walk that involved searching shallow water to a depth of around 0.4 m (Thoms et al. 1997. *In* Olson et al. [eds.], Sampling Amphibians in Lentic Habitats, pp. 35–46. NW Fauna 4, Soc. NW Vertebrate Biology, Olympia, Washington). In 1995–7, we similarly resurveyed nine of these sites twice yearly. We also made headlamp-assisted observations on 2–3 nights in all four years.

At 2330 h on 20 July 1994, we encountered two large (> 120 mm SVL) female Boreal Toads sitting ca. 0.5 m apart each within 15 cm of a Modoc Carpenter Ant (*Camponotus modoc*) column that was crossing the trail 30 m SW of Lake Elizabeth. Over the next five hours, we observed each toad take > 60 ants from the column. Feeding was irregular (3–18 min intervals between captures), and each toad made few movements, often capturing ants that strayed close rather than moving towards or interrupting the column to feed. Each toad stopped feeding ca. 30 min before sunrise. After feeding ceased, one female moved 35 m to the nearest lake margin to the NW; the other moved 80 m to the nearest lake edge to the SE. Each toad spent 10-15 min in shallow water after which each deposited a large, subovoid scat (25–30 x 10–13 mm).

Each scat had a gel-like translucent outer layer, which thickened slightly with hydration, and a dark interior. Examination of the interior revealed the scats to contain entirely carpenter ant parts. In one scat, the ant parts were entirely those of *C. modoc*; in the other, *C. laevigatus* and *C. modoc* parts were found. We made additional nocturnal observations of Boreal Toads feeding on carpenter ants on six different occasions during 1995–1997. Each observation began in the interval 2230–0250 h, and were similar in that adult toads were involved, toads posted on ant columns that crossed largely unvegetated patches, and in the four instances where we continued observations until the toads stopped feeding, each moved to shallow water and, after a period of 10–20 minutes, deposited one or two scats of a size and shape similar to that described above. In each case, scats were almost entirely *Camponotus* parts. The latter four observations differed from the above in that individual adults moved distances 15–285 m to the nearest water after feeding stopped, and cessation of feeding and movement to water occurred over the hour before sunrise.

Using VES in 1994, we found Boreal Toad life stages at nine sites: Big Heavenly Twin, Elizabeth, Isherwood, Liza, Florence, and North and South Snow Lakes, and two unnamed ponds (42°35'52"N, 122°11'27"W and 42°34'34"N, 122°12'32"W). During 1995–97 resurveys, which included Isherwood and Liza among resurveyed units, we found Boreal Toads at 4 sites, but recorded them in all resurvey years only from Isherwood and Liza. We also recorded them from Notasha and South Puck, respectively, only in 1995 and 1996. By contrast, we found evidence of reproduction (i.e., eggs, larvae, or metamorphosing toadlets) at only Isherwood and North Snow in 1994. During resurvey years, we recorded toad reproduction only at Isherwood every year and at Liza only in 1995.

After our initial observation of carpenter ant-filled scats in 1994, we were alert to similar-looking scats during VES. Ultimately, we recorded 47 carpenter ant-filled scats attributable to boreal toads in 20 different lakes and ponds in 1994, including 11 stillwater habitats at which we had not recorded boreal toads directly during VES. The latter were 4 named lakes (Deep, Martin, Tsuga, and Wind) and 7 unnamed ponds. Notably, Martin, Tsuga, and Wind were within 0.5 km of North Snow, one of two lakes with boreal toad reproduction (see above), whereas Deep and the remaining 7 ponds were within 0.6 km of Isherwood, the only other lake in which we identified toad reproduction. Similarly, during resurvey years, we found 13 toad scats at five sites, three at which we had not recorded toads during VES, and all of the latter were within 0.4 km of Isherwood.

Our observations are significant for three reasons. Data based on VES, a widely used method for amphibians (Thoms et al., *op. cit.*), had fewer than half the Boreal Toad sites than the scat data revealed. As Boreal Toads may be crepuscular or nocturnal (Linder and Fichter 1977. The Amphibians and Reptiles of Idaho. The Idaho State Univ. Press, Pocatello. 78 pp.), especially during the warmer months when many surveys are done, likelihood of making a Type II error about toad habitat use (not detecting a species when it actually uses a site) may be high, especially if one uses diurnal VES. Identifying the presence of toad scats offers one way to decrease Type II error if applying diurnal VES and perhaps other survey methods. This method needs further scrutiny to determine its effectiveness, but the approach might be more useful for high-elevation Boreal Toads. At high elevation, toads may be more dependent on carpenter ants, resulting in their consistently having more distinctive-looking scats that are less likely to be confused with those of other subalpine vertebrates, assemblages which are typically less speciose than their lower elevation counterparts. Second, all stillwater habitats where the only evidence of toad presence was scats found within 0.6 km of breeding sites shows that scat data can also augment understanding of the scale and foci of habitats used. This may be especially useful in landscapes densely populated with discreet stillwater habitats, such as the Sky Lakes Basin. Notably, aforementioned distances are in the range of reported movements for Boreal Toads (Muths, *op. cit.*; Carpenter, *op cit.*; Pimentel, *op. cit.*). Lastly, heavy carpenter ant use is consistent with the availability of this resource in high elevation systems, as several other organisms (e.g., woodpeckers) also heavily exploit this food source at high elevation (Torgersen and Bull 1995. Northwest Sci. 69:294–303).

Fieldwork was done under an Oregon Department of Fish and Wildlife scientific handling permit to MPH. The Bureau of Land Management, the Oregon Department of Fish and Wildlife, Pacificorp, The Nature Conservancy, Weyerhaeuser Company, and the U.S. Forest Service (Winema National Forest) contributed to the funding or logistics of this study. Aaron Borisenko, David Chiller, Lisa Krentz, Thomas Lossen, Kevin Pfeifer, and Chris Rombough assisted with fieldwork.

BUFO* cf. *CRUCIFER (Sapo Cururu). **DEFENSIVE BEHAVIOR.** Bufonids have characteristic paratoid glands on their dorsum that may help prevent predation (Stebbins and Cohen 1995. A Natural History of Amphibians. Princeton Univ. Press. 316 pp.). Field observations reported herein were carried out at the Ecological Station of Itirapina (ESI), municipality of Itirapina and Brotas, São Paulo State, southeastern Brazil. On 25 Nov 2002 an adult male *Bufo* cf. *crucifer* was found crossing a road at the ESI. At first, the individual tried to escape by making short and unidirectional hops for ca. 100 m. Apparently tired, it became immobile until my hand touched its back. The animal immediately tilted its body sideways in the direction that I had touched. When I touched its head, the animal flexed the head downward (Fig. 1A); when I touched its back, the anuran assumed a roughly erect posture, with its arms strongly stretched (Fig. 1B); when I touched one of the flanks, it tilted laterally toward the same side. This behavior may be common in species of the genus *Bufo* (Hanson and Vial 1956. Herpetologica 12:141–149; Duellman and Trueb 1994. Biology of Amphibians. McGraw-Hill Publ. Co., 670 pp.), although it has never been described for this species complex. This postural behavior 1) increases the likelihood that a predator might ingest toxic skin secretions; and 2) presents a large body surface that would make head-first ingestion (for example, by snakes) more difficult.

I thank Anne D'Heursel for comments on previous versions of the manuscript, Denise Zancheta for allowing access to Ecologi-

BUFO MARINUS (Marine Toad). **DEFENSIVE BEHAVIOR.** *Bufo marinus* occurs from extreme southern Texas (USA) through tropical Mexico and Central America to northern South America (central Brazil and Peruvian and Bolivian Amazon). It has been widely introduced (Antilles, Hawaii, Mauritius, Fiji, Philippines, Taiwan, Ryukyu Is., New Guinea, Australia, and many other Pacific islands) (Frost 2002. Amphibian Species of the World: an online reference. V2.21. http://research.amnh.org/herpetology/amphibia/index.html). On 6 July 2003, three juvenile *B. marinus* [Museu de Ciência e Tecnologia of the Pontifícia Universidade Católica do Rio Grande do Sul; MCP 7502, female, 39.2 mm SVL; MCP 7503, female, 42.5 mm SVL; MCP 7504, male, 51.4 mm SVL,] were collected in Itaituba municipality (04°29'40"S; 55°49'00"W), Pará State, Brazil. While being manipulated for photographs the specimens assumed a defensive behavior feigning death (Fig. 1). The posture observed during 45 sec was of retracted limbs and exposed belly. Defensive behavior is variable among Leptodactylidae, Hylidae, and Bufonidae (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins Univ. Press 670 pp.). A behavior similar to the one presented here has been observed in *Rhinoderma darwini* (Pough et al. 2001. Herpetology. 2nd Ed. Prentice Hall, New Jersey, 612 pp.), *Dendrophryniscus minutus* (Russel 2002. Herpetol. Rev. 33:302), and *Epipedobates femoralis*

ELACHISTOCLEIS* cf. *OVALIS (Common Oval Frog). **DEATH FEIGNING.** Numerous amphibian defense strategies have been described, including death feigning, or thanatosis, which is quite widespread in anurans. This strategy is utilized by members of several families including Bufonidae (Zamprogno et al. 1998. Herpetol. Rev. 29:96–97); Hylidae (Azevedo-Ramos 1995. Rev. Bras. Bio. 55[1]:45–47): Leptodactylidae (Hartmann et al. 2003. Herpetol. Rev. 34:50), and Ranidae (Gramapurohit et al. 2001. Herpetol. Rev. 32:103), although its function is still not well understood (Azevedo-Ramos, *op. cit.*). Observations reported herein occurred during January 2003 at Floresta Estadual "Edmundo Navarro de Andrade" (22°25'S; 47°33'W, 650 m elev.), municipality of Rio Claro, São Paulo State, Brazil. An adult male *Elachistocleis* cf. *ovalis* (25 mm SVL) was captured while calling and when manipulated for photographs, it turned its belly, arms, and legs up, with the arms outstretched and the legs close to the body (Fig. 1). The animal remained motionless for nearly 3 minutes. After resuming its normal position, the animal was handled again and it repeated the behavior twice. Rödel and Braun (1999. Biotropica 31[1]:178–183) described a similar behavior in *Kassina fusca*, although it was not identified as thanatosis. Thus this is the first observation of thanatosis in a microhylid, and the third defensive behavior described for the genus (Kokubum and Menin 2002. Herpetol. Rev. 33:198; Kwet and Solé 2002. Herpetol. Rev. 33:46). The effectiveness of death feigning needs to be tested as there are few data available that support the idea that such behavior could lead to avoidance by predators (Rödel and Braun 1999, *op. cit.*).

FIG. 1. Adult male *Elachistocleis* cf. *ovalis* feigning death after been handled.

I thank Cynthia Prado for helpful comments on previous versions of the manuscript, João Bosco for allowing the access to Floresta Estadual "Edmundo Navarro de Andrade," and IBAMA and Instituto Florestal for the authorizations provided.

Submitted by **LUÍS FELIPE TOLEDO**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil, Caixa Postal 199, CEP 13506-970; e-mail: toledolf@hotmail.com.

ELEUTHERODACTYLUS MIMUS (NCN). **DIET**. On 13 Jan 2003 at 1600 h at the La Selva Biological Station, Heredia Province, Costa Rica, an adult female *Eleutherodactylus mimus* (~45 mm SVL) captured and consumed an anole, *Norops limifrons* (~40 mm SVL; ~80 mm total). *Eleutherodactylus mimus* is not previously reported to take vertebrate prey.

The *E. mimus* jumped 13 cm vertically from the leaf litter to a small arching stick, apparently in response to movement of the *N. limifrons*. The frog bit the anole at midbody and dropped to the ground. The frog sat without moving, occasionally clenching its jaws while the anole struggled and appeared to gasp for air. After 15 min, the *E. mimus* used its forelegs to push the anole's head into its mouth with a lunging motion. Over a three-minute period, the *E. mimus* then swallowed the anole with quick, lunging bites followed by pauses. Once the anole had been completely consumed, it continued to move inside the frog for ca. 5 min, when the frog was captured by hand to verify identification.

Diet samples from 14 individuals of this species listed by Lieberman (1986. Acta Zool. Mex. 15:1–71) included no vertebrate prey. Lieberman reported that the greatest proportion of the diet is made up of termites (30%), orthopterans (20%), and miscellaneous larvae (20%). My observation suggests that occasional small vertebrate prey may be an important protein source for *E. mimus*.

I thank the Organization for Tropical Studies, Peace Frogs, and the Auburn University College of Agriculture, International Scholars Program for pilot funds supporting research during which this observation was made.

FEJERVARYA LIMNOCHARIS (Boie's Wart Frog). **OPHIOPHAGY.** Diet studies of *Fejervarya limnocharis* have been carried out in Japan (Hirai and Matsui 2001. Current Herpetol. 20[2]:97–103), China (Zhao 2001. Chinese J. Zool. 36[5]:43–45), and Vietnam (Kuzmin and Tarkhnishvili 1997. Adv. Amphib. Res. Form. Sov. Un. 2:103–109). None of these studies report *F. limnocharis* ingesting reptiles. On 27 July 2003 at 1914 h after heavy rains, in Myanmar, Shan State, Taung Gyi District, near Mine Thaung Village (20°34'39.8"N, 96°57'24.1"E datum WGS 84), G. Wogan and Kyi Soe Lwin found an adult *F. limnocharis* (California Academy of Sciences CAS 226161) on the ground with a half-ingested *Ramphotyphlops braminus* (CAS 226162). The *R. braminus* measured 122 mm total length and weighed 0.9 g. The *F. limnocharis* measured 40.6 mm SVL and weighed 7.8 g (after preservation). A second *R. braminus* (CAS 225157) was found within 3 m of the above animals, suggesting that they were active that night. Ophiophagy in *F. limnocharis* is likely opportunistic.

I thank U Khin Maung Zaw and U Than Htay, Nature and Wildlife Conservation Division, Forest Department, Ministry of Forestry, Myanmar, Van Wallach for confirming the identification of the *R. braminus*, Lihua Zhou for Chinese translation, Jeff Wilkinson for Japanese translation, and Alan Leviton, Jeff Wilkinson, and Jens Vindum for comments on this note. Funding was provided by NSF DEB 9971861.

HYLA CINEREA (Green Tree Frog). **DIET.** *Hyla cinerea* is commonly found on low-growing vegetation throughout the southeastern United States (Phelps and Lancia 1995. Brimleyana 22:31–45). Documented prey include 35 families of arthropods, with noctuid moth (Lepidoptera: Noctuidae) and soldier beetle larvae (Coleoptera: Cantharidae) the most commonly observed prey recorded from stomach samples (Freed 1982. Oecologia 53:20–26).

In August 2001, small forest gaps were created in bottomland hardwood forests on the Savannah River Site, Barnwell Co., South Carolina, USA. These gaps provide valuable habitat and resources for plants and animals that prefer open areas. In a recent survey, we found *H. cinerea* to be 7.5 times more abundant in the forest gaps than in the interior forest (unpubl. data). Previous researchers have noticed a similar preference for clearings by this species (Phelps and Lancia, *op. cit.*).

On 4 Sept 2003 (ca. 1030 h) we observed an immature *H. cinerea* (3–4 cm SUL) on switchcane (*Arundinaria gigantea*) in a 0.26 ha flooded canopy gap. The tree frog was observed consuming a narrow-winged damselfly (Odonata: Coenagrionidae). To our knowledge, this is the first record of *H. cinerea* preying upon this group of insects.

Dragonflies and damselflies (Odonata) occur in a number of habitats including streams, ponds, and swamps (Borror et al. 1981. An Introduction to the Study of Insects, 5th ed. Saunders College Publ., Philadelphia. 827 pp.). They seem to have benefited from the creation of forest gaps as they are much more abundant there than in the forest (pers. obs.). The most common prey of *H. cinerea* are immature insects, ants, spiders, or beetles which are weak fliers commonly found walking on vegetation (Freed, *op. cit.*). Although the majority of its prey may be small and slow-moving, our observation of *H. cinerea* catching and consuming such a large and actively flying insect shows it to be an opportunistic predator.

LEPTODACTYLUS FRAGILIS (White-lipped Foamfrog). **COURTSHIP.** Female reciprocal calling is a rare phenomenon in anurans and has been reported in only 14 species (Schlaepfer and Figueroa-Sandí 1998. Copeia 1998[4]:1076–1080). Two of these species are in the family Leptodactylidae, but none are *Leptodactylus*. Here we report an observation of courtship behavior and potential female reciprocal calling in *L. fragilis*. The observation took place in the canal area, Gamboa, Panama (9°07.0'N, 79°41.9'W).

During a rainy evening on 16 July 2003 we observed two *L. fragilis* apparently courting. One frog, almost surely a male, while hopping, intermittently emitted a characteristic advertisement call (Ibañez et al. 1999. The Amphibians of Barro Colorado Nature Monument, Soberania National Park and Adjacent Areas. Editorial Mizrachi & Pujol, Panama). The male called from open, exposed areas and kept moving, covering a distance of ca. 1.5 m during the period of observation. The other individual, presumably a female, followed him ca. 20 cm away. While this occurred, we heard a second type of call. This call was a rapid series of notes or short trill, longer and softer than the advertisement calls. Some of these calls were synchronized with movements of the abdomen of the male. Other calls were not and may have been given by the presumptive female. The second type of call, in contrast to the advertisement call, was barely audible at a distance of 2 m. While the male was broadcasting the second type of call, the other individual approached him until they were side to side, touching each other laterally. The male disappeared under some vegetation, apparently entering a burrow on the ground, and the other frog followed him. They were not seen again.

In *L. fragilis* males call during late afternoon and night during the rainy season (Ibañez et al. 1999, *op. cit.*). They construct burrows next to pools, where females deposit eggs (Heyer 1969. Evolution 23:421–428). Early development takes place within a foam nest until the burrow is flooded and the tadpoles reach the water (Ibañez et al. 1999, *op. cit.*; Prado et al. 2002. Copeia 2002:1128–1133). This reproductive mode is shared by members of the *L. fuscus* species group (Prado et al. 2002, *op. cit*). We are aware of descriptions of courtship behavior in *Leptodactylus* only for *L. fuscus* (Freitas et al. 2001. Comun. Mus. Ciênc. Technol. PUCRS, Sér. Zool., Porto Alegre 14:121–132) and *L. mystacinus* (Sazima 1975. Dissertação de Mestrado, USP Sao Paulo. 71 pp.). Touching was described to be present in both species. If the calling behavior that we observed in *L. fragilis* is associated with their reproductive mode, it is likely that female reciprocal calling occurs in other species of the *L. fuscus* group as well. The absence of previous reports may be explained by their secretive underground behavior that makes them difficult to locate and observe while breeding.

This observation was possible thanks to the support of NSF grant No. 0078150 to the University of Texas conducted to study *Physalaemus pustulosus* in the same area. We thank Stanley Rand for support and encouragement, Ron Heyer for comments on the manuscript, and the Smithsonian Tropical Research Institute for logistic support.

Submitted by **XIMENA BERNAL** (e-mail: xbernal@mail.utexas.edu) and **SANTIAGO R. RON** (e-mail: sron@mail.utexas.edu), School of Biological Sciences, Integrative Biology Section, University of Texas, Austin, Texas 78712, USA.

LEPTODACTYLUS OCELLATUS (Rã-manteiga). **TADPOLE ALBINISM.** Because they are more conspicuous to predators, albino individuals are expected to be relatively rare in nature (Sazima and Pombal 1986. Rev. Biol. 46[6]:377–381; Sazima and Di Bernardo 1991. Mem. Inst. Butantã. 53[2]:167–173).

On 4 Oct 2002, in the municipality of Uberlândia (Minas Gerais, Brazil), we found an albino *Leptodactylus ocellatus* tadpole. The tadpole was in a dense school of black siblings (>150 individuals) which was attended by an adult female, as is typical for the species (Vaz-Ferreira and Gehrau 1975. Physys 34, 88:1–14). The albino was in Gosner stage 25 (Gosner 1960. Herpetologica 16:183–190) and measured ca. 25 mm TL. Survival of this albino tadpole to a large size may have been facilitated by the schooling behavior and by maternal care.

We thank Ariovaldo A. Giaretta for critically reading the manuscript. FAPEMIG provided a fellowship to APR.

MEGAELOSIA BOTICARIANA (NCN). **ADULT SIZE.** *Megaelosia boticariana* is a rare and threatened species from southeastern Brazil (Giaretta and Aguiar 1998. J. Herpetol. 32:80–83). This species was diagnosed chiefly by its karyotypical features and the holotype is a female of uncertain degree of maturity; the two paratypes are juveniles. Herein we describe an adult male topotype (Parque Florestal do Itapetinga, Atibaia, São Paulo), housed at Museu de História Natural da Universidade Estadual de Campinas (ZUEC), Campinas, São Paulo. This male was found dead, from unknown causes, in a forest rivulet on 9 July 2000. Decomposition of this individual was not far advanced so that reliable measurements could be taken and morphological details analyzed as follows: adult male *M. boticariana* (ZUEC 11843); 100.4 mm SVL; vocal sacs visible externally as a thin whitish skin on each side of the head, slightly distended (inflated); each vocal sac with its correspondent vocal slit; tympanum ovoid, its diameter (parallel to the main body axis) being about 24% of the eye diameter; back smooth, uniformly gray; lower surfaces of thighs entirely smooth. Body proportions, in relation to SVL are: head length 37.8% (from posterior border of tympanum to tip of snout); head width 42.4%; thigh length 48.1%; shank length 47.8%; foot length 49.2%. In addition to the karyotypical features, the smaller size (about 13% in SVL) and lighter dorsal coloration help differentiate *M. boticariana* from *M. massarti*. SVL of this male *M. boticariana* (ZUEC 11843) is about 25% larger than the holotype (ZUEC 9561), which suggests the latter is a juvenile.

NYCTIXALUS PICTUS (Cinnamon Tree Frog). **DEFENSIVE BEHAVIOR.** *Nyctixalus pictus* is a common and widespread species from the Sunda regions of Southeast Asia, from southern Thailand, the Malay Peninsula, Sumatra, Borneo, and Palawan (Inger and Stuebing 1997. A Field Guide to the Frogs of Borneo. Natural History Publications [Borneo] Sdn Bhd., Kota Kinabalu, Sabah, Malaysia. 205 pp.). In our experience with this relatively com-

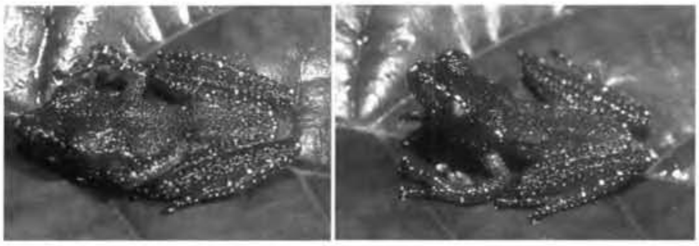

FIG. 1. Left: Defensive posture of *Nyctixalus pictus*, with eyes shut, back arched, and forearms covering part of head. Right: The same frog, ca. 30 secs later, in the more typical alert position.

mon rhacophorid species, about three out of four specimens handled will display a defensive response. Such behavior is herein described from observations of individuals encountered and/or collected in the field from different localities.

On 7 Aug 2003, while walking in the lowland dipterocarp forest, ca. 04°03'96"N, 114°51'99"E, 495 m elev., adjacent to the base of Sarawak Chamber, the largest cave chamber in the world, within the Mulu National Park, Sarawak, East Malaysia (Borneo), an adult female *Nyctixalus pictus* (31.4 mm SVL), was encountered sitting on a leaf of a sapling and was collected for photography. Upon manipulation of the frog, it closed it eyes, arched its back, and placed its forearms alongside its head with the palmal surface turned away from the body partially covering the posterior portion of the eyes (Fig. 1, left), at the same time, releasing a mossy smell. After ca. 30 secs, it returned to its typical position (Fig. 1, right), with eyes open, body upright, and hands and feet firmly on the ground. Similar reactions from individuals of this species have been elicited as a result of handling from other parts of Southeast Asia.

It is worth noting that *Nyctixalus pictus* shows a bright orange, red or cinnamon-brown coloration that may be considered aposematic, as is typical of many other species that show this "unken reflex".

We thank the Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, Universiti Brunei Darussalam, and the Department of Biological Sciences, National University of Singapore, for support of our research on the herpetology of Southeast Asia.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **REPRODUCTIVE BEHAVIOR.** The Cuban Treefrog (*Osteopilus septentrionalis*) was first recorded on mainland Florida in Dade County in 1951 (Schwartz 1952. Copeia 52:117–118). The subsequent spread of *O. septentrionalis* throughout peninsular Florida led to speculation concerning the impacts of this species on native anurans (Wilson and Porras 1983. The Ecological Impact of Man on the South Florida Herpetofauna. Univ. Kansas Mus. Nat. Hist. Spec. Publ. No. 9. 89 pp.; Meshaka 2001. The Cuban Treefrog in Florida. Univ. Press of Florida, Gainesville. 191 pp.). Here, I report an observation of reproductive interference by *O. septentrionalis* on a native anuran.

On 23 May 2003 at ca 0240 h, I observed a male *O. septentrionalis* in amplexus with a female Southern Leopard Frog (*Rana sphenocephala*) (Fig. 1). These individuals were found on the grassy margin of a drainage ditch in a residential development at the southeast corner of Kings and Lumsden Avenues in Brandon, Hillsborough Co., Florida. Thunderstorms had moved through the area late on 22 May. At the time of the observation, the air temperature was ca. 23°C and the relative humidity was 95%. *Osteopilus septentrionalis*, Eastern Narrow-mouthed Toads (*Gastrophryne carolinensis*), Pig Frogs (*Rana grylio*), and Florida Cricket Frogs (*Acris gryllus*) were calling from the drainage ditch. No other *R. sphenocephala* were seen or heard in this habitat, but several males were heard calling later from a retention pond ca. 200 m away.

FIG. 1. Male *Osteopilus septentrionalis* and female *Rana sphenocephala* in amplexus, Brandon, Hillsborough County, Florida.

This is the first published observation of reproductive interference by *O. septentrionalis*. The breeding calls of males of *R. sphenocephala* and *O. septentrionalis* are qualitatively similar (*pers. obs.*), but whether the female *R. sphenocephala* was drawn to the site by calling *O. septentrionalis* could not be determined. Although hybridization is a potential negative effect of nonindigenous species on native species (Simberloff 1997. *In* Simberloff et al. [eds.], Strangers in Paradise, pp. 3–17. Island Press, Washington, D.C.), hybridization between *O. septentrionalis* and *R. sphenocephala* seems unlikely since hybridization between families is uncommon. However, reproductive interference such as that reported here may decrease an individual's fitness if time and energy are spent in unsuccessful amplexus. The population-level effects of reproductive interference by *O. septentrionalis* on *R. sphenocephala* are probably minimal, however, since there is little temporal overlap in the breeding phenologies of these two species in Florida (Bartlett and Bartlett 1999. A Field Guide to Florida Reptiles and Amphibians. Gulf Publ. Co., Houston, Texas 280 pp.; Meshaka 2001, *op. cit.*).

These observations were made in conjunction with research supported by a U.S. Geological Survey Cooperative Ecosystem Study Agreement Grant. Ken Dodd and Sandy Echternacht commented on the manuscript.

Evolutionary Biology, 569 Dabney Hall, The University of Tennessee, Knoxville, Tennessee 37996-1610, USA.

PROCERATOPHRYS BOIEI (Smooth Horned Frog). **DEFENSIVE BEHAVIOR.** The leptodactylid *Proceratophrys boiei* has a large geographic range from northeast to southeast Brazil (Haddad and Sazima 1991. *In* Morelato [ed.], História Natural da Serra do Japi: Ecologia e Preservação de uma Área Florestal no Sudeste do Brasil, pp. 188–210). On 23 Oct 2003 an adult male (51.1 mm SVL) was captured in a semidescidual forest (Mata São José), at the municipality of Rio Claro, São Paulo State, Brazil (22°21'278"S; 47°28'722"W, 659 m). When manipulated for photographs the frog flattened its body, stretched its rear legs backwards and its front legs forwards. It remained motionless for about 5 minutes even when carefully touched on its back. This behavior was repeated whenever the animal was touched. Sazima (1978. Biotropica 10[2]:158) described a similar behavior in *P. appendiculata*, and suggested this behavior could enhance its appearance as fallen leaves, confusing visually oriented predators. It is also possible this posture could make the individual difficult for a predator to swallow or create a "hard-to-ingest-prey" image (Azevedo-Ramos 1995. Rev. Bras. Biol. 55[1]:45–47). This defensive strategy has been described in two species (*P. appendiculata* and *P. boiei*), suggesting that it could be a common behavior within the genus. Furthermore, this observation reinforces the suggestion that there is a behavioral convergence among anurans that inhabit leaf litter and are subject to similar predation pressures (Sazima 1978, *op. cit.*; Garcia 1999. Herpetol. Rev. 30:224).

We thank Joao R. Ennser and Celso A. Santos for help in the field. LFT also thanks to CNPq for providing a fellowship (proc. no. 130417/2003-3).

Submitted by **LUÍS FELIPE TOLEDO** (e-mail: toledolf@hotmail.com) and **JULIANA ZINA**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil, Caixa Postal 199, CEP 13506-970.

RANA AURORA (Northern Red-legged Frog) **HABITAT AND MOVEMENT**. Live trees retained in harvested areas may provide critical habitat for forest vertebrates that might otherwise disappear after timber removal (Franklin et al. 1997. *In* Kohm and Franklin [eds.], Creating a Forest for the 21st Century, pp. 111–140. Island Press, Washington, D.C.; Mitchell and Beese 2002. Forest. Chron. 78:397–403). Although the benefits of residual trees to birds (Tittler et al. 2001. Ecol. Appl. 11:1656–1666; Schieck et al. 2000. Forest. Ecol. Manag. 126:239–254) and mammals (Moses and Boutin 2001. Can. J. For. Res. 31:483–495; Sullivan and Sullivan 2001. J. Appl. Ecol. 38:1234–1252) have been well documented, the effects of residual trees on amphibians have received scant attention. Chan-McLeod and Moy (ms. submitted) recently quantified the 3-day use of residual trees by transplanted *R. aurora*, but longer-term use of residual trees by native amphibian inhabitants have not been documented.

Herein we report seven observations of resident, adult *R. aurora* in residual tree patches. The tree patches were located in three, 1-year old variable-retention cut blocks that had been harvested to leave 10–20% of the live trees standing as residual tree patches and as single residual trees. All frogs were observed in tree patches > 0.7 ha; none were observed in the cut matrix or in abundant, smaller tree patches. Most of the observed frogs were in tree patches that were close to or right at the cut block boundary. At cut block R799, two frogs were observed in a residual tree patch that was 50 m from a block boundary bordering a highway. The patch was 7424 m^2 in size and had an ephemeral stream that was dry when the frogs were observed. At cut block R818, four frogs were observed in two different tree patches. Two frogs were sighted at the edge of a 26,700 m^2 tree patch that was bordered by a running stream and a 13-year old regenerating stand defining the block boundary. Another two frogs were observed in an 8000 m^2 tree patch that was also at the block boundary and contiguous with an old-growth forest. One of these frogs was not actually a native inhabitant but had lived in or near the patch for the past year. This frog was transplanted to the residual patch the previous year in a failed attempt to radio-track its movements in the variable-retention cut block. The radio-transmitter failed soon after the frog was released, and it was not recovered until 12 months later when the frog was serendipitously observed, still wearing its failed transmitter, in the same residual tree patch < 3 m from where it was last observed a year earlier. At R800, a frog was observed in a 9670 m^2 tree patch located in the middle of the cut block and > 170 m from the nearest cut block boundary. The tree patch did not contain a wet stream but had two dry streambeds ending at its edge.

We were able to capture and radio-track four of the seven resident frogs. Three of the four radio-tracked frogs did not leave the tree patch where they were first observed; one frog was radio-tracked in the 7424 m^2 tree patch in R799 between 5–8 Aug; a second frog was radio-tracked from the 8000 m^2 tree patch in R818 between 1 July and 5 August; a third frog was radio-tracked from the same patch between 1–28 July. These three frogs were highly stationary and moved only a few meters between relocations, which were done at 1–3 day intervals. The frog that moved out of the patch from which it was first observed (7424-m^2 tree patch in R799) did so shortly after being radio-harnessed. The frog had crossed the 50-m matrix between the patch and the cut block boundary, then crossed the highway and was ca. 100 m up a forested slope on the other side of the highway when it was relocated two days after.

These observations were made during a frog movement study funded by Weyerhaeuser Ltd.

Submitted by **ANN ALLAYE CHAN-McLEOD** (e-mail: allaye@interchange.ubc.ca) and **BRAD WHEELDON** (e-mail: bwheeldo@sfu.ca), Department of Forest Sciences, 3041–2424 Main Mall, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z4.

RANA AURORA (Northern Red-legged Frog). **PREDATION.** Anurans have been at least occasionally recorded in Mallard (*Anas platyrhynchos*) diet, but historically, the species taken were not identified (McAtee 1918. U.S. Dept. Agric. Bull. [720]:1–36; Bent 1923. U.S. Nat. Mus. Bull. [126]:1–244; Martin and Uhler 1939. U.S. Dept. Agric. Tech Bull. [634]:1–156). Observations of wild Mallards consuming specific anurans, all relatively recent, remain infrequent. Mjelstad and Saetersdal (1989. Fauna norvegica Series C 12:47–48) recorded adult Mallards eating juvenile Com-

mon Frogs, *Rana temporaria*, in western Norway, and Eaton and Eaton (2001. Can. Field-Nat. 115:499–500) saw a female Mallard take an adult Wood Frog, *Rana sylvatica,* in central Alberta (Canada). Here, we augment available data on Mallard predation of anurans with observations of near-adult Mallards preying on juvenile Northern Red-legged Frogs (*Rana aurora*) in southwestern Oregon, USA.

We made the observations at a small (0.03 ha) pond on the Squaw Flat Research Natural Area (Tiller Ranger District, Umpqua National Forest; 42°57'52"N, 122°40'10"W; elev. 747 m) which is used by *R. aurora* for overwintering (unpubl. data) and is located ca. 50 m NE of a 0.6-ha pond used by the same species for breeding (Hayes et al. 2001. Herpetol. Rev. 32:35–36). Groundwater input gives the overwintering pond relatively stable water levels year-round. Except for a few clumps of low emergent vegetation along the N–NW shoreline, floating duckweeds (mostly Star Duckweed [*Lemna trisulca*]) and Watermeal (*Wolffia punctata*) cover most of the pond surface. A mature tree canopy of Douglas-fir (*Pseudotsuga menziesii*), Grand Fir (*Abies grandis*), Ponderosa Pine (*Pinus ponderosa*), and Madrone (*Arbutus menziesii*) keeps the pond relatively well shaded year-round. Little understory vegetation exists around the N half of the pond; in contrast, the S half has a dense Salal (*Gaultheria shallon*) bed that extends ≥ 10 m into the surrounding uplands. The pond has outflows on its NW and SW lobes, both of which drain into the aforementioned breeding pond.

While measuring *R. aurora* caught in this pond on 28 July 1998, we noted a pre-dispersal brood of seven subadult Mallards foraging in the pond. At 1510 h, we heard what sounded like the piercing scream (sensu Camp in Storer 1925. Univ. California Publ. Zool. 27:1–342) of a juvenile *R. aurora* coming from the NW lobe of the pond. After turning to examine the source of the sound, we saw one of the Mallards agitating the water in what appeared to be a frenetic search, but we could not identify the basis of its behavior. Two minutes after we had resumed processing frogs, we saw another of the Mallards make a flying run at the SW shoreline. Six meters in front of this duck, we saw a juvenile *R. aurora* (ca. 35 mm SVL) fleeing by rapid leaps over the dense duckweed mat in a shoreward direction. The Mallard caught the juvenile frog from behind just as it reached the shoreline, whereupon the frog gave a shrill scream identical to that heard earlier. Using two flips of its head, the Mallard swallowed the frog within 20 sec. As the other Mallards were still foraging in the pond, we stopped processing frogs to watch the ducks, in the event further predation might occur. Over the next 40 min, we witnessed different Mallards capture six more *R. aurora* juveniles, all in the 30–40 mm SVL range. Juvenile frogs were captured following chases lasting 15 sec to 6 min, and we heard one additional juvenile *R. aurora* make the shrill scream following its capture. During our subsequent survey of this pond, we captured five additional juvenile *R. aurora* in the size range taken by the mallards. These frogs averaged 34.5 mm SVL (range: 32.0–38.5 mm).

Two aspects merit comment. First, our observations suggest that amphibian prey may sometimes be more than incidental (see also Mjelstad and Saetersdal, *op. cit.*). We have observed a successful hatch and fledging from the only Mallard nest known to occur at this site in five of our six years of fieldwork there, so opportunity might exist for Mallard predation to alter frog recruitment if the predation levels we observed occur over extended periods. Second, apparent rarity of amphibians in Mallard diet may result in part from a bias against detecting more rapidly digestible animal food (Swanson et al. 1979. *In* Bookhout [ed.], Waterfowl and Wetlands—An Integrated Review, pp. 47–55. The Wildlife Society, Washington, DC), like frogs or anuran larvae. Direct observations may be important in testing this possibility.

A conservation grant from Oregon Zoo Foundation supported this research; this work represents a contribution from the Science Division of the Habitat Program of the Washington Department of Fish and Wildlife. A permit to handle *R. aurora* was issued by the Oregon Department of Fish and Wildlife.

RANA CATESBEIANA (Bullfrog). **GIGANTIC TADPOLE.** North American Bullfrog tadpoles are known to attain a large size and take 1–3 years to metamorphose, however, there are few accounts of maximum size for Bullfrog tadpoles or other anuran species (McDiarmid and Altig 1999. Tadpoles, the Biology of Anuran Larvae. Univ. Chicago Press, Chicago. 444 pp.). Bullfrog tadpoles normally range from 76–170 mm (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida, Part Three. The Amphibians. Windward Publishing Inc. 191 pp.; Wright 1929. Proc. U.S. Nat. Mus. 74:1–70). However Dickerson (1969. The Frog Book. Dover Publ., Inc. New York. 253 pp.) reported *R. catesbeiana* tadpoles can attain 177 mm. On 31 July 2002, we collected a 190 mm (total length) Bullfrog tadpole (Gosner stage 37, Fig. 1) from Nevens Pond, Keith County, Nebraska (41.20710°N, 101.4085°W), a small cattle tank overflow pond. To our knowledge this is the largest Bullfrog tadpole ever reported. Other tadpoles from this location were also large (ca. 150–160 mm TL), although none was comparable in size to this giant. Collins (1979. Ecology 60:738–749) indicated that biotic factors, especially density of conspecifics and the time of oviposition influence variation in size at metamorphosis of Bullfrogs. Additionally, abundant food and lower water temperatures during development increase anuran time to and body size at metamorphosis. We have no density data on the number of tadpoles from Nevens Pond, although our observations suggest that it was comparable to other ponds that had smaller Bullfrog tadpoles. Unfortunately, this gigantic individual died while being transported back to the laboratory, and we cannot say if this giant could transform into a froglet. Allen (1917. J. Exp. Zool. 26:499–519) produced giant tadpoles in *R. pipiens* by performing thyroidectomies on young tadpoles, and it may be that this individual did not posses a thyroid gland. However, two other large tadpoles collected from this locality (but not measured) metamorphosed in the laboratory, yielding froglets 65–70 mm SVL, indicating that some large tadpoles can metamorphose from this pond. The reported variation in tadpole size and size at metamorphosis in *R. catesbeiana* is probably related to the number of years that tadpoles took to metamorphose. To our knowledge, these are some of the largest newly transformed Bull-

FIG. 1. *Rana catesbeiana* tadpole Gosner stage 37. Bar = 50 mm.

frogs (see Collins *op. cit.*) and it suggests that some Bullfrogs at Nevens Pond take three years to develop before metamorphosing. During late summer and early fall most adult frogs in the large population at Nevens Pond look emaciated, probably due to a food shortage. It is unlikely that these Bullfrogs can migrate to other ponds during this time of year to feed, because of the large distances between ponds and the dry conditions of the sand hills of western Nebraska. We suspect that it might be advantageous for Bullfrog tadpoles at this location to metamorphose at a larger size to prevent being preyed upon by conspecific metamorphosed Bullfrogs, which are gape-limited predators.

We thank Richard J. Wassersug and Irena Rot-Nikcevic, Department of Anatomy and Neurobiology, Dalhousie University, Halifax, Nova Scotia, Canada for sharing their information on tadpoles and tadpole literature and reviewing the manuscript, and Melissa Ewert, Brigham and Women's Hospital, Harvard Medical School Teaching Affiliate, Boston, Massachusetts for reviewing the manuscript. We also thank the Nebraska Game and Parks Commission for scientific collecting sub-permit to MGB (Sub-Permit No. 226), Cedar Point Biological Station, University of Nebraska–Lincoln for laboratory space, and Brent Nickol, School of Biological Sciences, University of Nebraska–Lincoln for the use of his animal room. This work was supported by grants from the Initiative for Ecological and Evolutionary Analysis, University of Nebraska–Lincoln; The Franklin Kestner Memorial Fund, School of Biological Sciences, University of Nebraska–Lincoln; and the Center for Great Plains Studies graduate student Grant-in-aid, University of Nebraska–Lincoln.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). **COLORATION AND BEHAVIOR.** Both albinism (Childs 1953. Evolution 7:228–233) and aggregational behavior (Richmond 1947. Ecology 28:53–67; Bragg 1954. Herpetologica 10:97–102) have been previously observed among larval *Scaphiopus* spp. in various parts of the United States, mostly from central and western parts of the country. Herein, we report the discovery of two leucistic-like *S. holbrookii* tadpoles within larval aggregations at the Brookhaven National Laboratory, Upton, Suffolk County, New York, USA (40°52'20"N, 72°52'04"W).

During field research on 16 June 2003, we encountered *S. holbrookii* tadpoles in a temporary pool that had formed in a grassland area after a period of heavy precipitation. We estimate that the pool contained thousands of tadpoles, most of which were participating in several mass aggregations. Based on observations by Bragg (1954, *op. cit.*), the aggregations we found were likely feeding aggregations. At ca. 1700 h, we observed two leucistic-like tadpoles that were quite obvious among the black background created by their aggregating cohorts (Fig. 1). Using dip nets we captured both individuals in ca. 20 cm of water and brought them back to the lab for rearing.

The coloration of both tadpoles was identical. Their bodies were pale beige, but their eyes exhibited the dark color of a normal tadpole. Snout–vent length for the two tadpoles was 16 and 17 mm at time of capture. We maintained the tadpoles in captivity for 97 days, but the larvae failed to reach metamorphosis. To our knowledge, this is the first report of leucistic-like tadpoles and breeding aggregations for this species in New York.

SCINAX FUSCOMARGINATUS (NCN). **DEFENSIVE BEHAVIOR.** Anurans are known to be an important component in the diet of a large number of predators, although they have evolved several defensive mechanisms (Duellman and Trueb 1994. Biology of Amphibians. McGraw-Hill Book Co. 670 pp.). Some of the defensive mechanisms are shown by some hylid species (Azevedo-Ramos 1995. Rev. Bras. Bio. 55[1]:45–47; Manzanilla et al. 1998. Herpetol. Rev. 29:39–40; Napoli 2001. Herpetol. Rev. 32:36–37), however there is lack of descriptions of any of these

behaviors for *Scinax* species. Field observations were carried out in the Ecological Station of Itirapina (22°13'S; 47°54'W, 725 m elev.), municipalities of Itirapina and Brotas, São Paulo State, Brazil. Approximately 200 male *Scinax fuscomarginatus* were handled between October 2002 and March 2003. When handled they exhibited at least three identifiable defensive strategies: 1) to escape, some individuals jumped into the water staying submerged motionless for over two minutes while holding onto the submerged vegetation; 2) every adult male was noted to perform death feigning (thanatosis), with its belly, arms, and legs upturned, remaining immobilized for less than 1 min in most of cases, but for over 12 min during one observation; and 3) males inflated their lungs, puffing up the body for ca. 30 sec. The first strategy suggests the frog might be looking for a shelter to avoid possible terrestrial predators; nevertheless, the frog becomes exposed to aquatic predators instead (Hinshaw and Sullivan 1990. J. Herpetol. 24[2]:196–197; Haddad and Bastos 1997. Amphibia-Reptilia 18:295–298). Likewise, the efficiency of the two other strategies remains unrecognized (Azevedo-Ramos 1995, *op. cit.*). Data suggesting that sheltering underwater, feigning death, or creating a larger image actually reduces the risks of predation in most of Neotropical anurans (Azevedo-Ramos 1995, *op. cit.*) are lacking.

I thank Cynthia Prado for valuable comments on a previous version of this manuscript, Denise Zancheta for allowing access to the Ecological Station of Itirapina, IBAMA and Instituto Florestal for the authorization provided, CNPq (proc. no. 130417/2003-3) for a fellowship, and Idea Wild for the donation of equipment.

SMILISCA BAUDINII (Mexican Treefrog). **EGG PREDATION.** During June and July 2002, one of us (KK) found an apparent predator of the eggs of *Smilisca baudinii* near Las Cuevas Research Station (LCRS), in the Chiquibul Forest Reserve, Cayo District, Belize. The predator (Fig. 1) was vermiform, ca. 2–3 mm in length at time of emergence from frog eggs, and was found only within the eggs of *S. baudinii*. Herein we refer to this organism as a "worm" for lack of a more appropriate term, although its identity has not been determined. Under a compound light microscope at 300x, cilia were visible on the outside of the organism, and structures that appeared to be eyespots also were evident. Six of 10 clutches seen in June, and 1 of 50 clutches observed in July and August, were infested with this worm. Infected eggs displayed an amorphous gray region within the jelly, in place of the usual discrete black sphere. Every egg in an infested clutch contained one worm and was non-viable; no tadpoles hatched from any infected eggs. We do not know if the worms killed and consumed viable eggs, or if they entered eggs that were unfertilized or that had died from some other cause. On one occasion, KK found infested and non-infested clutches on the same day in the same pond. Infested clutches were found in two temporary ponds about 1 km apart, but not in an intervening permanent pond, nor in another temporary pond 5 km distant, despite the presence of *S. baudinii* eggs at all four sites.

KK collected portions of several infested clutches and held them in plastic containers containing pond water. Worms emerged from the frog eggs within 24 h, which is within the range that uninfected eggs would be expected to hatch (Pyburn 1966. Southwest. Nat. 11:1–18). Upon emerging from the frog eggs, worms were free-living, at first congregating along the edges of the container and then swimming throughout the water column 2–3 days later. Eggs were visible within the worms (Fig. 1) when they were viewed under a dissecting scope shortly after they emerged from the frog eggs, and eggs were found in the water after 3–4 days. Smaller worms were found in the containers several days after collection. Several worms were preserved in formalin and returned to Cleveland State University for identification. Specimens are available for loan upon request. Living specimens have been examined at LCRS by Dr. Jon Martin of the Natural History Museum, London, and images and/or preserved specimens have been examined by Drs. David Green of the USGS, Charles R. Bursey of Pennsylvania State University, Shenango, and Skip Sterner of the Manter Parasitology Lab, University of Nebraska, experts in anuran disease, platyhelminths, and nematodes, respectively. To date, identification of the organism is unknown.

Throughout much of its wide geographical distribution, *S. baudinii* is abundant, yet it may be less common than would be expected in the Las Cuevas area (Fitzherbert et al. 2001. Project Anuran Phase I Main Report). The worms described herein could be an important source of mortality for *S. baudinii* and possibly for other anurans in the Las Cuevas area. Many of the ponds in the vicinity of LCRS are heavily stained with organic matter or clouded with suspended material. Most species of anurans that reproduce at these ponds deposit their eggs within the water column or on the bottom, where they can be difficult to examine closely. The Mexican Treefrog, however, deposits its eggs in a dispersed monolayer at the surface where they can be observed closely, even if the water is opaque. This frog therefore may have represented one of the best opportunities at LCRS to detect this worm. Its apparent absence from the eggs of other anurans at LCRS may be as attrib-

Fig. 1. Photomicrograph of an unidentified predator found in the eggs of the Mexican Treefrog. The image is of a contracted specimen preserved in formalin a few days after it emerged from a frog egg. Scale bar represents 100 micrometers. The dark spots near the right end of the image may be eyespots. The oval masses within the body of the organism are assumed to be eggs.

utable to difficulty of observation as it is to possible specificity by the worm to the eggs of *S. baudinii*. We plan to continue to assess the impact of this apparent egg predator on anurans at LCRS, and to describe more fully the nature of the frog-predator relationship. We encourage others with the opportunity to examine the eggs of *S. baudinii* and other pond-breeding tropical anurans to look for this predatory organism.

We thank Barbara K. Modney for photographing the specimen. The Belize Forestry Department issued permits for research at LCRS and for export of organisms. The Columbus Zoo and Aquarium and the Department of Biological, Geological, and Environmental Sciences of Cleveland State University provided funding that made this research possible. We thank Las Cuevas Research Station and the Natural History Museum, London, for permission to use their site, and the staff at LCRS for aide and expertise in the field. We are grateful to Jon Martin for help in examining and preserving the specimens at LCRS, and to David Green, Charles Bursey, and Skip Sterner for examining the specimens or photographs thereof. Julian C. Lee reviewed the manuscript and provided much helpful advice.

CROCODYLIANS

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **NEST and NESTLING ECOLOGY.** The ecology of hatchling *Alligator mississippiensis* has been studied over much of its range. Yet, information on the ecology and natural history of *A. mississippiensis* within Arkansas, the northwesternmost part of its range, is particularly sparse. Here we help fill this gap with *A. mississippiensis* observations from southeast Arkansas.

On 7 August 2001, we found the first *A. mississippiensis* nest on record at Arkansas Post National Memorial, Arkansas County since prior to the 1980s (pers. comm., Kevin Eads, Resource Management Specialist, Arkansas Post National Memorial). This nest, located along Alligator Slough (a backwater of the Arkansas River) on the west side of the park, was ca. 2 m from the shore, 30 cm high and 1–1.5 m in diameter, and constructed of grasses and water lily leaves. No female was observed at the nest. We excavated only enough of the nest to reveal > 10 eggs. More eggs were apparent under the first layer, but we chose not to disturb them and repaired our excavation. Further searching of both banks of the slough and the rest of the park did not reveal more nests. Eggs in this nest were evidently close to hatching as Eads (pers. comm.) informed us that the nestlings emerged in mid-September.

At 2200 h on 12 April 2002, we returned to the nest site and observed 22 hatchlings within a 50-m radius of the original nest site. Numerous ghost shrimp (*Natantia* sp.) were present. While observing the hatchlings forage, they appeared to be feeding on these shrimp. Hatchlings averaged 31.6 mm TL (SD = 1.9, N = 5), 14.9 mm SVL (SD = 0.7, N = 5), and 81.7 g (SD = 7.6, N = 3) in mass.

Our observations suggest that spring body sizes of hatchlings from Arkansas may be substantially smaller than those in other parts of its range. Hatchlings (N = 220) from South Carolina that were 24.5 cm TL (SD = 1.4; 50 g, SD = 5.4) in September reached 36.2 cm TL (SD = 5.4; 128 g, SD = 5.2) the following May (Brandt 1991. Copeia 1991:1123–1129). This may indicate slower growth rates in Arkansas. Resource limitations caused hatchling *A. mississippiensis* from the Everglades to grow slower (i.e., ca. 16 cm/yr), and mature at a smaller size and at an older age than those known elsewhere in alligator range (Dalrymple 1996. Copeia 1996:212–216). Little research exists on growth rates and seasonal body sizes in *A. mississippiensis* from Arkansas; however, the longer winter may limit resources in a manner similar to the pattern observed in the Everglades, explaining why our May body sizes were smaller than those observed in South Carolina during May (Brandt, *op. cit.*).

The basis of the smaller size of Arkansas hatchlings has management implications because juvenile survivorship is size-specific; probability of death decreases as an individual grows (Rootes et al. 1991. Estuaries 14:489–494), and age is often determined by their size. It is crucial to know whether alligator growth is actually slower in Arkansas than in other parts of its range. At reduced growth rates, smaller animals may be vulnerable to a larger predator set for a longer interval. Thus, management of *A. mississippiensis* in Arkansas would require a somewhat different approach than in the more southerly parts of its range. More information is needed regarding growth rates of *A. mississippiensis* in Arkansas to effect proper management.

TESTUDINES

CHELONIIDAE (Marine Turtle). **NEST PREDATION**. On 19 June 2003 at 0217 h, an Opossum (*Didelphis virginiana*) was observed for 10 min while digging into a marine turtle nest and eating 4 eggs on the beach at St. Lucie Inlet Preserve State Park (SLIPSP) on Jupiter Island, Florida. The predation event was observed using night vision equipment as part of nightly patrols to protect turtle nests from Raccoon (*Procyon lotor*) and Armadillo (*Dasypus novemcinctus*) predation during the nesting season (Engeman et al. 2003. Biol. Cons. 113:171–178). After verification of an ongoing predation event, the Opossum was euthanized and removed. Prior to implementing predator removal on this beach, up to 95% of the turtle nests were destroyed annually by Raccoons (Bain et al. 1997. Sea turtle nesting and reproductive success at the Hobe Sound National Wildlife Refuge (Florida), 1972–1995. Report to U.S. Fish and Wildlife Service, ARM Loxahatchee NWR). In recent years, Armadillos, a species exotic to the east coast of Florida, have become severe predators of turtle nests (Bain et al., *op. cit.*; Engeman et al., *op. cit.*). While Foote

(2000. Proc. Sea Turtle Symp. 18:189–190) lists Opossums as incidental predators at marine turtle nests, our observation is the first that identifies an Opossum as a primary predator (excavator) of a marine turtle nest.

Three species of marine turtles nest on the SLIPSP beach: Loggerhead (*Caretta caretta*), Green (*Chelonia mydas*), and Leatherback (*Dermochelys coriacea*). Based on the ca. 60-cm depth of the nest, the nest could have belonged to either a Loggerhead or Green Turtle, but because nearly 90% of the marine turtle nests on the beach are Loggerhead (Engeman et al., *op. cit.*), the Opossum-predated nest most likely was Loggerhead. A Leatherback nest was unlikely, because it was too shallow and Leatherbacks nest infrequently on this beach (Engeman et al., *op. cit.*).

When a mammalian predator is not observed directly, determination of the species responsible for turtle nest predation is typically based on tracks. Our observation indicates that marine turtle researchers should pay close attention to track nuances, because superficial observation of a tail drag in the sand at a predated nest may not implicate an Armadillo as the predator. Care should be taken to also verify the footprints of the animal responsible. Opossum footprints are easily distinguished from Armadillo prints, because Opossum prints are hand-like with five digits on each foot, whereas Armadillo prints have all toes facing forward with claws usually evident and only four digits on the front feet (Murie 1974. A Field Guide to Animal Tracks, 2nd Edition. Houghton Mifflin Co., Boston, Massachusetts. 375 pp.).

CHELYDRA SERPENTINA (Snapping Turtle) **and *SCAPHIOPUS HOLBROOKII*** (Eastern Spadefoot). **PREDATION and DIET.** Snapping turtles are known to have an extremely wide and varied diet (Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Institution Press, Washington D.C. 578 pp). Here we note predation on the larvae of *S. holbrookii*.

On 16 June 2003, at 1000 h, while conducting fieldwork at the Brookhaven National Laboratory (Upton, Suffolk County, New York, USA [40°53'24"N, 72°52'27"W; WGS84/NAD83]) we observed a female *C. serpentina* submerged in ca. 15 cm of water with several *S. holbrookii* tadpoles clenched in her jaws. This observation was made adjacent to a dirt road in a depression that had filled with water following heavy precipitation. Thousands of *S. holbrookii* tadpoles were observed in the flooded depression, and these tadpoles may constitute an important seasonal food source for *C. serpentina* in temporarily flooded habitats. Predation on *S. holbrookii* by *C. serpentina* has been documented previously (Ernst et al. 1994, *op. cit.*), but to our knowledge, this is the first documentation of predatory interaction for these two species in New York.

Submitted by **JEREMY A. FEINBERG**, United States Fish and Wildlife Service, Brookhaven National Laboratory, Building 120, 81 Cornell Avenue, Upton, New York 11973, USA (e-mail: jerfein@aol.com), and **KRISTINE HOFFMANN**, University of Massachusetts - Amherst, P.O. Box 413, 113 Flanagan Hill Road, Sterling, Massachusetts 01564, USA (e-mail: khoffman@student.umass.edu).

DEIROCHELYS RETICULARIA (Chicken Turtle). **DIET**. Predation can be a key factor affecting the diversity and structure of larval aquatic amphibian communities (Azevedo-Ramos et al. 1999. Copeia 1999:22–33; Gomez-Mestre and Keller 2003. Copeia 2003:349–356). The role of reptiles and amphibians as predators of tadpoles may be more widespread than appreciated (e.g., Aresco and Reed 1998. Herpetol. Rev. 29:40; Beard and Baillie 1998. *ibid;* Gomez-Mestre and Keller 2003). Two recent studies (Jackson 1996. Chelonian Cons. Biol. 2:105–108; Demuth and Buhlmann 1997. J. Herpetol. 31:450–453), based on gut and fecal analyses, have confirmed *Deirochelys reticularia* as a specialized predator of aquatic organisms, chiefly arthropods, in the southeastern U.S. Although Carr (1940. Univ. Florida Publ., Biol. Sci. Ser. 3[1]:1–118; 1952. Handbook of Turtles: The Turtles of the United States, Canada, and Baja California. Cornell Univ. Press, Ithaca, New York. 542 pp.) noted seeing *Deirochelys* feed upon both dead and live tadpoles, neither of the recent studies identified amphibians as an important dietary component. Demuth and Buhlmann (1997, *op. cit.*) suggested, however, that this may relate to the lack of conspicuous, indigestible parts among amphibian larvae, which might conceal their presence because of rapid digestion. Here I report several instances of wild-caught *Deirochelys* consuming a large number and diversity of amphibian larvae offered to them in captivity, as well as an additional observation from nature.

In February 1997, I obtained two gravid female Chicken Turtles (197 and 173 mm plastron lengths) from Grady County, Georgia. Following induction of oviposition via oxytocin injection, turtles were maintained in a tank measuring 71 x 30 cm and filled with water to a depth of 22 cm. On 12 April I provided a large sample of living potential prey netted from a seasonal pond in Leon County, Florida. The sample included mostly odonate (dragonfly) nymphs, crayfishes, and approximately 150 larval amphibians, chiefly *Rana sphenocephala, Pseudacris* spp., and *Ambystoma talpoideum*. Amphibians measured 20–60 mm in total length (TL) and comprised ca. 80% of the sample biomass. Within 30 minutes, only three small beetles remained uneaten.

Subsequently, I experimentally introduced tadpoles to three other adult *Deirochelys* collected in northern Florida. From May-August 2000, an adult female (170 mm PL; Franklin County), whose fecal analysis indicated a typical diet of aquatic arthropods (crayfish, *Procambarus* sp.; aquatic hemipterans, *Ranatra* and *Pelocoris*), consumed the following tadpoles in captivity: 7 very large *Rana grylio* (100 mm TL, 10 g mass; body girth exceeded turtle's head diameter), 2 *R. sphenocephala* (20, 85 mm TL), 1 *R. clamitans* (45 mm TL), 8 *Acris gryllus* (25 mm TL), 1 *Hyla chrysocelis* (55 mm TL), 42 *H. femoralis* (30 mm TL), 2 *H. gratiosa* (50 mm TL), and 34 *Gastrophryne carolinensis* (25 mm TL). Many of the more advanced tadpoles bore hind legs. The turtle also ate a juvenile *Bufo terrestris* (20 mm body length).

Another adult female turtle (175 mm PL; Leon County) consumed four 30-mm *R. clamitans* tadpoles offered to it on 13 January 2000. An adult male (125 mm PL; Wakulla County) consumed 32 of 42 *R. sphenocephala* tadpoles (30–60 mm TL) within three days of the 20 April 2002 offering date. When fed conspecific tadpoles (35–50 mm TL) again one year later, it ate all 50 offered within 48 hours, as well as seven odonate nymphs. In none of the instances cited was there evidence, in the form of rejection, that any of the prey species was unpalatable to *Deirochelys* (contrast results for *Mauremys leprosa*: Gomez-Mestre and Keller 2003).

At least one herpetologist besides Carr has observed *Deirochelys* feeding on tadpoles in nature. M. A. Nickerson (pers. comm., 2003) observed an individual feeding on *Rana* tadpoles in a roadside ditch in Butler County, southeastern Missouri, in late spring 1983.

Amphibian larvae comprise a major if not principal component of the animal biomass in many seasonal ponds. Because of their ephemeral nature, such ponds typically lack predatory fish species large enough to prey upon most larvae. However, vertebrate predators that are not bound to water, such as turtles and snakes, may have a major predatory role in limiting (or even extirpating) amphibian larvae in such systems (Newman 1987. Oecologia 71:301–307; Gomez-Mestre and Keller 2003, *op. cit.*). In the southeastern U.S., the Chicken Turtle is one of the few reptiles that regularly inhabit such ponds. With its ability to strike prey rapidly, it can easily capture resting or schooling amphibian larvae and thus is a potentially important predator of the amphibian community, as may be turtles occupying similar habitats elsewhere (e.g., *Pseudemydura umbrina*: Kuchling 1999. The Reproductive Biology of the Chelonia. Springer. 223 pp.; *Emys orbicularis*: Gomez-Mestre and Keller 2003, *op. cit.*). At least three species of conservation concern (*Rana capito*, *Ambystoma cingulatum*, and *Notophthalmus perstriatus*) are among the roughly two dozen amphibian species that breed in ephemeral ponds that are sometimes occupied by *Deirochelys*.

I thank John Palis for insightful comments on an early draft, Max Nickerson for sharing his field data, and Caroline Coile, Karl Studenroth, Jr., Jean-Jacques Delaruelle, and Thierry Bourget for capturing the experimental turtles.

Submitted by **DALE R. JACKSON**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

GOPHERUS AGASSIZII (Desert Tortoise). **ASSOCIATION WITH AFRICANIZED BEES.** In the Sonoran Desert, *Gopherus agassizii* often utilize rocky outcrops and caliche caves as shelter sites (Van Devender 2002. *In* Van Devender [ed.], The Sonoran Desert Tortoise: Natural History, Biology, and Conservation, pp. 3–28. University of Arizona Press, Tucson). Native vertebrates and a variety of invertebrates also use these shelter sites. Here we report observations of Desert Tortoises sharing shelter sites with Africanized Honey Bees (*Apis mellifera scutellata*), a recent immigrant to the desert southwest.

During a radio telemetry study east of Tucson, Arizona in 2001 and 2002, four *G. agassizii* frequented (were found on > 20 weekly tracking occasions) rock outcrops or caliche caves with large, active, Africanized Honey Bee colonies. Tortoises freely moved in and out of the occupied shelters and appeared not to disturb the bees, even when within 0.5 m of the colony. However, when we approached with radio telemetry equipment, bees quickly became agitated. On warmer days (≥ 20°C), these occupied shelters with hives could not be approached to within 5 m without bees acting very aggressively toward us. On one occasion (April 2001), one of us (EWS) was chased > 50 m by an agitated colony but was not stung. In two additional encounters with different hives, (June 2002) we were stung before we could escape the infested area.

Africanized Honey Bees are the result of an accidental release in Brazil in the mid 1950s, and have slowly spread north into the southwestern United States. They reached Tucson, Arizona in 1993 (Kunzmann et al. 1995. *In* LaRoe, et al. [eds.], Our Living Resources: A Report to the Nation on the Distribution, Abundance and Health of U.S. Plants, Animals, and Ecosystems, pp. 448–451. USDI Nat. Biol. Serv., Wash. D.C.) and quickly displaced existing populations of non-native European Honey Bees (*Apis mellifera*). Distance sampling of Africanized Honey Bee colonies and tortoises indicates that both species occur at high densities in desert areas of Saguaro National Park (DES, unpublished data). Desert Tortoises apparently do not elicit bee attacks; perhaps their cool body temperatures, low carbon dioxide emissions, and slow movements are factors.

Thanks to Justin Schmidt (Southwestern Biological Institute) and the University of Arizona Herpetology Journal Review Group for reviewing this note.

GOPHERUS AGASSIZII (Desert Tortoise). **MOVEMENT**. In the Sonoran Desert, *Gopherus agassizii* occurs in rocky foothills associated with saguaro cactus (*Carnegiea gigantea*) and foothill paloverde (*Parkinsonia microphylla*) characteristic of Upland Sonoran Desert Scrub plant community (Turner and Brown 1992. *In* Brown 1992. Desert Plants 4, pp. 180–221). Although these populations appear to be isolated by low desert valleys, radiotelemetry data have shown that tortoises are capable of making long distance movements between populations (Barrett et al. 1990. Final report, Bureau of Reclamation, Arizona Projects Office, Phoenix; Averill-Murray and Klug 2000. Technical Report 161, Arizona Game and Fish Dept., Phoenix). Long-distance movements between disjunct populations may facilitate genetic exchange (Britten et al. 1997. Copeia 1997:523–530) and be important for long-term maintenance of populations. Here we report an extraordinary movement by a female *G. agassizii* and the anthropogenic barriers encountered during this event. We show that, while Desert Tortoises are capable and sometimes motivated to make inter-population movements, the urban topography of our modern landscape makes such movements increasingly difficult.

We affixed a radio transmitter (AVM G3, AVM Industries, Colfax, California) to an adult female *G. agassizii* (238 mm MCL, 2700 g) on 14 August 2000, as part of an ongoing study in the

Rincon Mountains at Saguaro National Park (SNP; 32°08'N, 110°41'W), Tucson, Arizona. At the time of transmitter attachment, the tortoise presented signs of upper respiratory tract disease (URTD; nasal discharge, wheezing, occluded nares, and exudate). Other tortoises at this study site have tested positive for *Mycoplasma agassizii*. We located the tortoise approximately every week. By 06 September, she had moved ca. 500 m SW of the original capture location. We then lost contact with her until 18 September when a SNP volunteer observed the tortoise along a roadway ca. 1.5 km S of the original locality (32°06'N, 110°41'W). On 25 September, we found her ca. 8 km further south on a rocky slope surrounded by low-density housing (32°02'N, 110°40'W). The terrain between these locations is primarily flat ground dominated by creosote bush (*Larrea tridentata*) and is atypical of Sonoran Desert tortoise habitat (Barrett 1990. Herpetologica 46:202–206). On 2 October, we found her on private property along a chain-link fence. We obtained permission and put her across. At this time, we affixed a note to the tortoise's carapace indicating she was part of a study at Saguaro National Park and included a contact phone number. We believe the tortoise over-wintered in Arizona Upland Sonoran Desert Scrub on a large expanse of private land; however, we did not receive a signal from her between 2 October 2000 and late July 2001.

On 31 July 2001 we were contacted by a resident who had found the tortoise in Vail, Arizona, in the middle of a paved street at a railroad crossing (ca. 15 km S of where she was first marked; 32°03'N, 110°42'W). We placed her south of the railroad tracks (within 0.5 km E of the crossing), oriented in the same general direction she was moving but away from residential housing. Over the next two months, we received three phone calls from residents who had found the tortoise and brought her home. Each time, we returned the tortoise to uninhabited areas in the vicinity. During this period she remained within 1.5 km N of Interstate 10 (a four-lane freeway due south of Vail), and traversed an approximately 3-km east-west distance. We made an *a priori* decision to facilitate the tortoise's movement across Interstate 10 if she continued moving south.

On 29 August 2001, we located the tortoise on a frontage road beside I-10 (32°01'N, 110°42'W) and decided to transport her across the interstate. We placed the tortoise on a north-facing slope of the Santa Rita Mountains ca. 7 km S of the interstate, where we observed tortoise sign (31°55'N, 110°42'W). We decided the 7-km distance was necessary because medium density housing and many fences bisect land south of the interstate. The tortoise made several east-west movements along the foothill slopes at the new location, and on 18 September, 2001 we were contacted by a landowner who found her in the middle of a new residential development, 5 km W of the release point (31°54'N, 110°53'W). We collected her and returned her to the original release site in the Santa Ritas. She spent the winter of 2000–2001 in the north end of the Santa Rita Mountains. We periodically found the tortoise at this same location until June 2002, when her transmitter failed prematurely. Not including the human-facilitated movement of ca. 7 km, this tortoise moved more than 30 km straight-line distance over the span of one year.

On 22 August 2002, we were contacted yet again by a family who found her on Interstate 10 under an overpass (32°01'N, 110°43'W), 7 km N of her overwintering site, toward the original capture site. We changed transmitters and re-released her at the first point of capture, at the south end of Saguaro National Park. She has remained at this site through the winter of 2003. The tortoise currently presents signs of URTD, but did not do so consistently since the time of transmitter attachment.

It seems unlikely that the behavior exhibited by this tortoise was in response to stress caused by initial handling because we have placed transmitters on > 70 tortoises since 1992 and no other tortoises have made long distance movements. Occasionally, within 24 h of being handled, tortoises will move from the capture site, but less than 1 km. It is possible that humans other than researchers facilitated portions of the movements reported here, particularly during the initial 8 km movement during 18 – 25 September 2001, which crossed two roads. However, the tortoise had already begun an unusually long movement through an unpopulated area to reach the first road from the study site (1.5 km) and was in atypical habitat.

This tortoise encountered several barriers that, without human facilitation, would likely have been insurmountable. A residential fence and an interstate highway both required human assistance to cross. We believe a set of railroad tracks may also have acted as a barrier and that the tortoise followed them for some distance before encountering a place to cross. Lastly, we note that at least four residents collected the tortoise and contacted us. It is possible the tortoise would have become someone's illegal pet if the identifying label had not been affixed to the carapace.

This project was funded by the Arizona Game and Fish Department Heritage Grant Program, the National Park Service, the Southwestern Parks and Monuments Association, and the US Geological Survey. Research was conducted under scientific research permits from the Arizona Game and Fish Department and the National Park Service. Tortoise handling protocols were approved by the University of Arizona (IACUC 00-084). We thank Kevin Bonine and Caren Goldberg for reviewing an earlier version of this note.

GRAPTEMYS OUACHITENSIS SABINENSIS (Sabine Map Turtle). **REPRODUCTION.** A clutch size of one egg (the minimum possible) has long been regarded as one expression of tropical adaptation in turtles (Moll and Legler 1971. Bull. Los Angeles Co. Mus. 11:1–102). Although not a tropical turtle, *G. ouachitensis* has a wide latitudinal distribution in North America (Vogt 1993. Cat. Am. Amphib. Rept. 603:1–4). We here report on its reproduction from close to the lowest latitudinal limit of its range (29.8°N; Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge, 300 pp.). Our data reflect on several aspects of reproduction, including intraseasonal clutch frequency, and clutch, egg, and hatchling size. We made 11 independent visits to nesting habitat in Louisiana and

Texas (from 30.6° to 31.1°N) during six years from 1972 to 2002. All data came from recently laid nests or dissection of female reproductive tracts.

The reproductive tract of a nongravid female collected on 16 May had numerous enlarged follicles. One female from 13 June and two females from 18 June contained two sets of corpora lutea, which indicate production of an initial clutch in late May or early June. Dates with recent nests or with females found gravid on land spanned 13 June 16 July. Reproductive tracts from eight females indicated productive capabilities of two clutches (by 1 turtle), three clutches (by 3 turtles), and two or three clutches (by 4 turtles) during the season.

Clutch size varied between one and four eggs, with a mean clutch size for 55 clutches of 2.34 ± 0.80 SD eggs, which includes means of 1.96 ± 0.49 SD (N = 30) for the Calcasieu River and 2.80 ± 0.87 SD (N = 25) for the Sabine River. The average mass of 61 eggs was 9.85 ± 1.44 SD g (from the Sabine habitat only) and of 94 hatchlings was 7.38 ± 1.17 SD g (36 from the Calcasieu at 7.6 ± 0.8 SD g; 58 from the Sabine at 7.2 ± 1.3 SD g).

One-egg clutches comprised 11% of the total and were found along both the Calcasieu River (N = 4) and the Sabine River (N = 2). However, 4-egg clutches (N = 5) came only from the Sabine. The modal clutch size was 2 eggs. Four of the 4-egg clutches came from June and one from July. Five of the six 1-egg clutches came from July, suggesting that clutch size declines during the season. We did not observe any 6-egg clutches as reported by Dundee and Rossman (1989, *op. cit.*), and their report left reason to question the assignment of such a clutch to *G. o. sabinensis* (Dundee, pers. comm.). However, we cannot rule out the occurrence of such clutches in *G. o. sabinensis* at localities farther north in the Sabine drainage.

That *G. o. sabinensis* has single-egg clutches and a small mean clutch size becomes appreciably more interesting in a contrast with the mean clutch size of *G. o. ouachitensis* from near the high latitude limit of the species distribution (i.e., 10.9 eggs; range: 6–17 eggs, N = 99; 43.7°N latitude; from Vogt 1980. Tulane Stud. Bot. Zool. 22:17–48 [fig 2], plus Janzen et al. 1995. Funct. Ecol. 9:913–922). Thus, across the range of *G. ouachitensis* there is a 4.66-fold difference in mean clutch size. This proportional difference may be the largest in any North American species of turtle. In contrast, the high latitude mean egg size of 10.97 g and hatchling size of 8.21 g (Vogt 1980, *op. cit.*; Janzen et al., *op. cit.*) differ relatively little from low latitude values (given above). The low latitude eggs and hatchlings are not larger as might be expected in a tradeoff between clutch size and egg size (sensu Smith and Fretwell 1974. Am. Nat. 108:499–506; Roosenberg and Dunham 1997. Copeia 1997:290–297). In absolute measures, no such tradeoff is apparent in this latitudinal comparison.

We thank Richard Anderson, Amanda Rosenzweig, Mark Antwine, and Jason Hatfield for helping with the fieldwork and Fred J. Janzen for measuring some of the hatchlings. Portions of the dissected females have been deposited at the Carnegie Museum of Natural History, Pittsburgh (CM8756877).

RHINOCLEMMYS AREOLATA (Furrowed Wood Turtle). **MAXIMUM SIZE**. The maximum straight-line carapace length (CL) given for *Rhinoclemmys areolata* is up " to 20 cm" (Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press, Washington, D.C. 313 pp.). On 28 July 2002 we found the intact shell of a female *R. areolata* with a CL of 20.7 cm (CUSC 2124) in the grassy margin between Cohune (*Orbigyna cohune*) forest and a citrus plantation (17°18.188'N; 88°31.213'W) on Tiger Sandy Bay Farm, Mile Marker 31, Western Highway, Cayo District, Belize. The turtle appeared to have been killed by a mowing machine several weeks previously. Large pieces of eggshell were found inside the shell indicating the female was gravid when killed. This specimen was deposited in the Campbell Museum, Clemson University, Clemson, South Carolina, USA.

We thank Steve Downard for allowing access to his property, Richard and Carol Foster for logistic support, and Earl Codd of the Belize Forest Department for issuing our research and collecting permit (Ref. No. CD/72/2/02 -173).

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). **POPULATION CHANGES**. *Terrapene carolina* populations often consist of long-term, long-lived resident individuals (Stickel 1978. Copeia 1978:221–225; Williams and Parker 1987. Herpetologica 43:328–335; Schwartz and Schwartz 1991. Copeia 1991:1120–1123; Schwartz 2000. Chel. Conserv. Biol. 3:737–738; Dodd 2002. North American Box Turtles, A Natural History, Univ. Oklahoma Press, 231 pp.). I studied a small suburban population of box turtles in my yard in West Point, Clay County, Mississippi (USA) (33°35'14"N, 88°37'46"W) from 1979 to 2003. The triangular yard was about 0.3 ha, partially wooded with mostly water oaks and some hackberry, sycamore, mimosa, and poplar. Most of the natural ground vegetation was cleared away and the yard fenced in the rear by 1985 and replaced with brick walks, flower gardens, fern beds, and border plants such as *Liriope*. Space under the fence still enabled access by turtles. Mowed lawns characterized the front and backyards of virtually all neighbors. Less-disturbed habitat for box turtles remained behind houses across the street in a horse pasture and adjacent patches of oak-hickory woodland.

Turtles were individually marked by notching marginal scutes of the carapace with a pocket saw, measured for carapace length (CL) to the nearest 0.1 mm with vernier calipers, and weighed to the nearest 0.1 g on an Ohaus mechanical balance. Overall, I marked and released 23 individual box turtles, as follows in 5-

year intervals (number of individuals, total captures): 1979–1983: 14, 21; 1984–1988: 3, 6; 1989–1993: 4, 14; 1994–1998: 3, 4; 1999–2003: 5, 6. None of the individuals captured in the latest group had been captured before 1999. Sex ratio was biased toward females (3:1) from 1979–1983, even (1:1) from 1984–1998, and all females from 1999–2003.

Sixteen of the 23 individuals were captured in only one year and two females in three years. Four individuals were longer-term residents, or at least visited the yard in more than one year over longer intervals: one female over four years (CL 108.0 in 1990, gravid road kill in 1994); one female in six consecutive years (1988–1993, growth below); one adult male captured in 1979 (CL 117.8), 1983 (CL 125.7), and 1988 (CL 125.7); and an older adult male captured in 1983, 1993, 1994, and 1996 (CL 123.5, no change during 13 years). One hatchling was captured in 1993.

One female was captured in six consecutive years (1988–1993) and illustrated growth from about age 7 to age 12 (CL, mm; weight, g): May 1988: 90.1, 138.1; June 1989: 100.0, 236.4; August 1990: 127.1, 400.1; August 1991: 137.2, 515.4; June 1992: 138.0, 545.5; July 1993: 141.0, 569.1 (estimated age based on plastral annuli).

With habitat alteration, road mortality, and possibly removal of box turtles for pets, this sparse population may have have declined. However, only the female in the previous paragraph, among the 23 marked and released, seemed to be a consistent resident. Other recaptured individuals were not seen in the yard for years and probably visited it at only irregular intervals. Transients from 1998–2003 have appeared healthy and included an adult male (CL 128.0), two juveniles (CL 81.4, 79.2), and two adult females (CL 131.0, 135.0), indicating a possibly viable source population.

LACERTILIA

ANELYTROPSIS PAPILLOSUS **(Mexican Blind Lizard). DEATH FEIGNING AND AUTOTOMY**. Almost nothing is known about the natural history of the distinctive blind lizard, *Anelytropsis papillosus*; the few available data are taxonomic (Campbell 1974. Cat. Amer. Amphib. Rept. 156.1; Greer 1985. J. Herpetol. 19:116–156). Here, we provide a preliminary report on its death feigning and caudal autotomy.

On 21 November 1996, two of us (RJTC and XHI) collected an adult male *A. papillosus* (137 mm SVL, 22 mm tail length, 3.5 g) under an old *Yucca carnerosana* trunk in xerophyll scrub at Rancho Nuevo, municipality of Guadalcázar, San Luis Potosí, México (22°52'0.1"N,100°10'1.1"W; elev. 1200 m). When first picked up, this individual responded by aggressively biting the collector's fingers continuously and intensely for 3–4 min. Immediately afterwards the *A. papillosus* became motionless in the collector's hand. The animal was relaxed, but slightly rigid, with a half open mouth, and adopted any position when manipulated. Engaging in this behavior, it appeared dead. After 2–3 min, it began to move slowly. Similar behavior was exhibited by a second adult male *A. papillosus* (136 mm SVL, 82 mm tail length, 3.8 g) that was collected 19 April 1999, under an old yucca trash log in xerophyll scrub along a road near Presa El Tepetate, also in the municipality of Guadalcázar (22°56'40.7"N, 100°13'52.8"W; elev. 1345 m). However, unlike the first *A. papillosus*, it remained motionless for only 10–15 sec after biting the collector's fingers. It acquired the same relaxed position, but in an S-shape. Subsequently, it made a sudden lash that autotomized almost half its tail (40 mm), and tried to escape the collector.

The Rancho Nuevo (IBH 13926) and Presa El Tepetate (IBH 1327) specimens were deposited in the herpetological collection of the Instituto de Biología, UNAM, and were obtained under collection permit DOO 750.10664/98 from SEMARNAP. We thank the authorities of the region and the local teacher Francisco Ávila-Pineda for help during the fieldwork. CONACYT Project 27618-N and CONABIO Project R045 supported this study.

ANOLIS EQUESTRIS **(Knight Anole). ENDOPARASITES.** *Anolis equestris* is native to Cuba and has been introduced to Oahu, Hawaii, where it was first noticed in 1981 (McKeown 1996. A Field Guide to Reptiles and Amphibians in the Hawaiian Islands. Diamond Head Publishing, Inc., Los Osos, California. 172 pp.). Helminth parasites of *A. equestris* in Cuba are listed in Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville. 720 pp.). The purpose of this note is to report two nematode species heretofore unknown in *A. equestris* from Hawaii.

Seven (2 female, 5 males) *A. equestris* (mean SVL = 141 mm ± 26 SD, range: 82–156 mm) collected on Oahu, Hawaii in 1999, 2000, and 2003 were examined for helminths. Lizards were deposited in the University of Michigan Museum of Zoology (UMMZ), Ann Arbor, Michigan, USA: UMMZ 226789–226791 and the Bishop Museum (BPBM), Honolulu, Hawaii, USA: BPBM 14821, 14822, 14998, 61961. The esophagus, stomach, small intestine and large intestine were opened and separately examined for helminths under a dissecting microscope. The body cavity was also searched. Three third-stage nematode larvae (*Physaloptera* sp.) were found in the large intestine of one *A. equestris* (UMMZ 226789). Cysts containing third-stage nematode larvae of *Physocephalus* sp. were found in the stomach wall or mesentery of six *A. equestris*. For *Physocephalus* sp., prevalence (number infected/number examined x 100) was 86% and mean intensity (mean number nematodes/infected lizards) was 99 ± 95 SD, range: 9–269. The nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as *Physaloptera* sp. (USNPC 93696) and *Physocephalus* sp. (USNPC 93697).

Neither *Physaloptera* sp. or *Physocephalus* sp. have been reported from *A. equestris* in Cuba (Schwartz and Henderson, *op. cit.).* Third-stage larvae of *Physaloptera* sp. (adults absent) are frequently found in amphibians and reptiles. Their occurrences were summarized in Goldberg et al. (1993. Bull. South. California Acad. Sci. 92:43–51). Hanley et al. (1998. Oecologia 115:196–205) reported *Physaloptera* sp. in *Hemidactylus frenatus* from

Oahu, Hawaii; Goldberg et al. (2003. Bishop Mus. Occas. Pap. Rec. Hawaii Biol. Survey 2001–2002. Pt 2: Notes, 74:72–76) reported them in *Phelsuma guimbeaui* from Oahu and *Phelsuma laticauda* from the Big Island, Hawaii. Encapsulated infective *Physocephalus* sp. larvae are commonly found in tissues of vertebrates that have ingested infected beetles (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission. CABI Publishing, Wallingford, Oxon, UK. 650 pp.). Cysts containing *Physocephalus* sp. have been reported in a variety of lizards from Hawaii (Goldberg and Bursey 2000. J. Parasitol. 86:750–755; Goldberg et al. 2003, *op. cit.*). *Anolis equestris* is an accidental host for *Physaloptera* sp. since the nematodes would have been voided from the large intestine with the feces. It is a paratenic (= transport host) for *Physocephalus* sp. since no further development occurs. Development to the adult stage occurs when *A. equestris* is eaten. This represents the first report of larvae of *Physaloptera* sp. and *Physocephalus* sp. in *Anolis equestris.*

ANOLIS LUCIUS (Coronel, Gorrita). **VOCALIZATION.** *Anolis lucius*, a Cuban endemic (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Florida Univ. Press, Gainesville. 720 pp.), inhabits coastal scrubwoods and semideciduous forests typically in association with limestone soils and outcrops (Rodríguez-Schettino 1999. *In* Rodríguez-Shettino [ed.], The Iguanid Lizards of Cuba, pp. 104–380. Florida Univ. Press, Gainesville, Florida). Some authors have described a sharp squeak when individuals are grasped (Barbour and Ramsden 1916. Mem. Soc. Cubana. Hist. Nat. Felipe Poey 2:124–143; Schwartz and Ogren 1956. Herpetologica 12:91–110; Allen and Neill 1957. Herpetologica 13:246–247; Ruibal 1964. Bull. Mus. Comp. Zool. 130:475–520; Peters 1970. Mitt. Zool. Mus. Berlin 46:197–234; Rodríguez-Schettino, *op, cit.*), but the gender or age of vocalizing animals has not been addressed. Herein we provide a quantitative description of the vocalizations produced by adult male and female *A. lucius*.

We recorded the calls of 11 *Anolis lucius* collected during October 2002 in Sierra de Najasa, Camagüey Province, Cuba. All recordings were made within 12 h of capture. We evoked vocalizations by gently grasping each animal between thumb and forefinger and orienting it within 10 cm of a Sennheiser ME 80 (K30 AV) microphone connected to a Marantz PMD-430 cassette recorder. Sounds were digitized at a sampling frequency of 44.1 KHz and 16 bits resolution, using an IBM Pentium computer fitted with Sound Blaster Live 1024 Sound Card and Batsound 2.1 software. Numerical data, sonograms, oscillograms, and power spectra were also obtained with the Batsound 2.1 sofware. Spectral variables considered were: fundamental frequency (FF), measured as the most intense frequency of the first harmonic on the sonogram; highest frequency (HF), measured at the upper frequency trace of the sonogram; and dominant frequency (DF); the frequency value at peak amplitude in the call's power spectrum. Call duration was measured to the nearest 0.01 s on the oscillograms. Measurements were averaged across individuals. The snout–vent length (SVL) of each individual was measured to the nearest 0.1 mm with Vernier calipers. We recorded air temperature (AT) at the site using a Miller-Weber quick-reading thermometer (± 0.2°C).

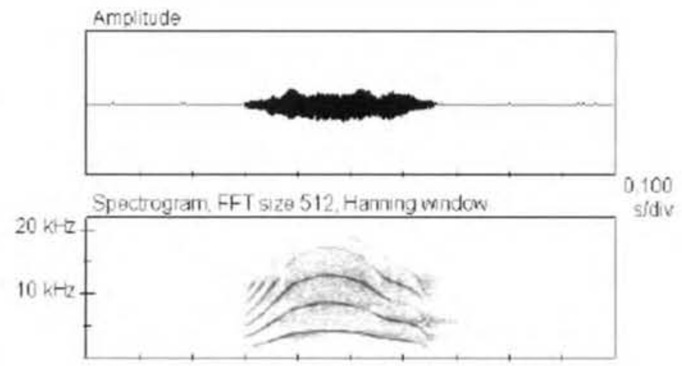

FIG. 1. Oscillogram (top) and sonogram (below) of one call of a male *Anolis lucius* recorded at La Belén, Sierra de Najasa, Camagüey province, Cuba. Air temperature = 26.5°C.

Eleven of 15 (73%) individuals vocalized in response to the procedure by producing short and high-pitched calls or "squeaks" with a clear harmonic structure (3–12 harmonics) distributed over a broad frequency range (Fig. 1). Generally, the first or second harmonic were dominant (mode = 2). Variation in vocalization variables for male and female *A. lucius* are summarized in Table 1. All acoustic properties analyzed varied considerably for the successive calls of a given subject and between different individuals (see Table 1). The air temperature, stable during the recordings (28.5 ± 0.1°C), should not have influenced acoustic feature variability. Despite the 13.2 mm range of variation in body size, acoustic parameters were not significantly correlated with lizard SVL.

The biological significance of these vocalizations is unclear, but we have also observed free-living animals emitting these calls during agonistic encounters with conspecifics. Moreover, the multi-

TABLE 1. Descriptive statistics of the acoustic features measured in vocalizations of *Anolis lucius*. For each parameter the mean, SD, and coefficient of variation (as %; in parens) are shown.

Gender Groups	CD ms	FF kHz	DF kHz	HF kHz	SVL mm
Males	0.33 ± 0.07	2.93 ± 0.75	4.89 ± 0.79	14.87 ± 1.31	58.11 ± 6.08
N = 8	(20.7)	(25.8)	(16.1)	(8.8)	(10.5)
Females	0.20 ± 0.03	2.51 ± 0.76	4.22 ± 0.62	12.95 ± 1.83	55.11 ± 3.57
N = 3	(12.4)	(30.5)	(14.8)	(14.1)	(6.5)

harmonic structure of these signals resembles selected distress or protest calls that have been documented in some mammals (Vencl 1977. Amer. Nat. 111:777–782; August 1985. Southwest. Nat. 30:371–375; Russ et al. 1998. Anim. Behav. 55:705–713), birds (Marler 1957. Behaviour 11:13–39; Neudorf and Sealy 2002. Biotropica 34:118–126), and frogs (Hoff and Moss 1974. Copeia 1974:533–534; Weber 1978. Copeia 1978:354–365; Höld and Gollmann 1986. Amphibia-Reptilia 7:11–21).

Historically, anoline lizards generally have been considered voiceless even though some Caribbean species have been known vocalize when individuals are grasped, as has been reported for several Cuban species: *Anolis isolepis* (Rodríguez-Schettino, *op. cit.*), *A. vermiculatus* (Neill and Allen, *op. cit.*; Ruibal, *op. cit.*; Peters, *op. cit.*), *A. bartschi* (Peters, *op. cit.*), and *A. jubar* (Rodríguez-Schettino, *op. cit.*). Also, *Anolis grahami iodurus* and *A. opalinus* from Jamaica are known to produce a sharp squeak when in distress or when fighting (Grant 1940. The Herpetology of Jamaica. II, Reptiles:88). Sound production in Caribbean *Anolis* does not appear to be restricted to members of an ecomorph class or to any phylogenetic groupings (Jackman et al. 1997. *In* Givnish and Sytsma [eds.], Molecular Evolution and Adaptive Radiation, pp. 535–557, Cambridge University Press, Cambridge). Detailed study will be needed to understand the basis of interspecific variation in anoline vocalization and identify their potential evolutionary significance.

We are grateful to Luis F. de Armas, Daysi Rodríguez, Hiram González, and Lourdes Rodríguez-Schettino for helpful suggestions on earlier drafts. Angel Daniel, Ignacio Ramos, and Rafael Borroto ably assisted in fieldwork. The Cuban project "Vertebrados de Cuba Central" of the Institute of Ecology and Systematics partly funded the fieldwork. Our thanks to the workers of the Protected Area "La Belen", Sierra de Najasa, Camagüey for their hospitality and help during our fieldwork.

ANOLIS STRATULUS (Saddle Anole). **EXTRAFLORAL NECTIVORY**. Nectivory or nectivory-like behavior has been recorded in lizards (Dearing and Schall 1992. Ecology 73:845–858; Eifler 1995. Oecologia 101:228–233; Font and Ferrer 1995. Herpetol. Rev. 26:35–36; Sáez and Traveset 1995. Herpetol. Rev. 26:121–123), including polychrotid anoles (*A. stratulus* from flowers: Perry and Lazell 1997. Herpetol. Rev. 28:150–151; *A. carolinensis* from hummingbird feeders: Liner 1996. Herpetol. Rev. 27:78), but extrafloral nectivory is undocumented among lizards. Here, I document extrafloral nectivory in *Anolis stratulus*, a medium-sized anole (48 mm maximum SVL) that frequently occurs in the forest canopy. This species is widely distributed in lowlands and intermediate elevations (up to 500 m) in mountains throughout Puerto Rico (Rivero 1998. The Amphibians and Reptiles of Puerto Rico, 2ed. Editorial de la Universidad de Puerto Rico, San Juan, 510 pp.).

Between 1200 and 1300 h on 20 July 2002, I observed an adult (ca. 40 mm SVL) male *Anolis stratulus* at a height of 1.5 m on a leaf of *Inga vera* (Leguminosae-Mimosoideae), a tree that can reach 15 m or more in height, on a karst hillside in Sabana Seca (18°27'N, 66°12'W), north coastal Puerto Rico. The anole was lapping nectar from the stipitate glands, which are located between opposite leaflets of *I. vera*'s compound leaves (Liogier 1988. Descriptive Flora of Puerto Rico and Adjacent Islands, vol. 2. Editorial de la Universidad de Puerto Rico, San Juan, 481 pp.). The anole lapped each of the four glands in sequence from the base of the leaf to its terminal axis. After 2–3 minutes of lapping nectar, the anole jumped to a nearby tree trunk and began displaying.

Anolis stratulus typically consumes ants (Wolcott 1924. J. Dept. Agric. Porto Rico 7:5–37; Lister 1981. Ecology 62:1548–1560; Reagan 1996. *In* Reagan and Waide [eds.], The Food Web of a Tropical Rain Forest, pp. 321–345. University of Chicago Press, Chicago, Illinois), but the extrafloral nectar of *Inga vera* in Puerto Rico, if similar to that of *I. vera* in Costa Rica, is energy and amino acid rich, and available continuously (i.e., nectar production occurs day and night: Koptur 1994. Biotropica 26:276–284). In general, extrafloral nectaries of *Inga* are visited by several species of ants that protect young leaves from insect herbivores (Koptur, *op. cit.*). In Puerto Rico, the ant, *Myrmelachista ramulorum* (NCN), which is predominantly arboreal, tunnels the stems of its domicile plants, and has a diet based largely on nectar and the exudate of homopterans (J. Torres, pers. comm.; Torres 1984. Biotropica 16:284–295). This ant species also occurs in Sabana Seca and elsewhere (the El Verde rain forest of northern Puerto Rico). *Myrmelachista ramulorum* is the most common ant in the diet of *A. stratulus* taken from understory and canopy strata (Reagan, *op. cit.*). Thus, extrafloral nectivory in *A. stratulus* may have evolved from the anole being exposed to the nectar while predating on ants of *M. ramulorum* which in turn, were feeding on extrafloral nectaries. Such a behavior would be advantageous for the anole at times when ants, its primary prey, were not abundant. Further, presence of *A. stratulus* on *I. vera* could also benefit the plant as anti-herbivore protection when other nectar feeding mutualists are rare or absent. The documentation of extrafloral nectivory deserves attention not only because it addresses a novel feeding behavior in lizards, but also for the possible influences of this behavior on the relationships among anoles, ants, and plants. This behavior might have consequences for plant fitness in islands like Puerto Rico, where anoles are among the most abundant diurnal insectivores (Reagan, *op. cit.*).

I thank Juan A. Torres for life history information on *M. ramulorum* and Frank Axelrod, U.P.R.-Río Piedras Herbarium, for confirmation of *I. vera*'s identity. I am indebted to Marc P. Hayes for valuable comments on an earlier version of the manuscript.

BRIBA BRASILIANA (Lagartixa). **PREDATION**. Records of predation on Brazilian geckos are scarce. Here, we report predation on *Briba brasiliana* by the burrowing owl *Speotyto cunicularia* (Aves: Strigidae) from central Brazil.

The observation occurred on 14 June 2003 at 2045 h in Parque Estadual do Jalapão (10°19'S, 46°53'W; elev. 400 m), municipality

of Ponte Alta, Estado do Tocantin. *Briba brasiliana* occurs in low densities in open habitats in the park and is sympatric with three other geckos (*Coleodactylus meridionalis*, *Gymnodactylus geckoides* and *Hemidactylus mabouia*). The predation event occurred in an area of cerrado *sensu stricto* (a savanna-like formation). We were conducting a night survey when we encountered a burrowing owl (*Speotyto cunicularia*) resting in an undeveloped roadway track on sandy ground. On approach, we saw that the owl was carrying a lizard in its claws as it flew off. The owl landed ca. 40 m away in the same roadway and then presumably killed the gecko with a bite to its head. On our second approach, we startled the owl and it flew off, leaving the gecko, which was almost intact; only bite marks on its head were evident. The gecko was an adult male *B. brasiliana* (65.5 mm SVL, 42.0 mm tail length).

Lizards are occasional prey of *Speotyto cunicularia*, but predation on *B. brasiliana* has not been previously reported (del Hoyo et al. 1999. Handbook of the Birds of the World. Vol. 5. Barn-owls to Hummingbirds. Lynx Ed., Barcelona, 759 pp.). *Briba braziliana* is a presumptively rare Brazilian gecko known from a handful of sites in northeastern Brazil and little is known of its ecology (Vanzolini et al. 1980. Repteis das Caatingas. Academia Brazileira de Ciencias. 161 pp.). This is the first record of predation on this species.

The gecko was deposited in the Coleção Herpetológica da Universidade de Brasília, Distrito Federal (CHUNB 30911).

CELESTUS CYANOCHLORIS (NCN). **ARBOREAL BEHAVIOR.** Largely due to inaccessibility, the biology of many vertebrates that inhabit tropical rainforest canopies is poorly known. Some anguid lizards, such as *Celestus hylaius* from the Atlantic lowlands of Costa Rica, are thought to be arboreal (Savage 2002. The Amphibians and Reptiles of Costa Rica, The University of Chicago Press, Chicago. 934 pp.), but, as with most cryptozooic forms, few observations exist. Here we report an observation of the poorly known anguid, *Celestus cyanochloris*, in the rainforest canopy providing preliminary evidence for arboreal behavior.

At 1400 h on 10 July 2003 (first half of rainy season), we encountered an adult *C. cyanochloris* (ca. 200 mm TL; full tail) 26 m above the forest floor in a tree (*Myrsine* sp.) along the Sky Walk tourist complex near Santa Elena, Costa Rica (84°95'N, 10°35'W; elev. 1450 m). The tree crown extended 4 m above the surrounding canopy, and the lizard was perched ca. 1 m from the tip of the branch closest to the Sky Walk bridge. The branch, ca. 75 mm dia, was laden in epiphytes: mosses, young bromeliads (predominantly *Tillandsia* spp.), and orchids. The lizard remained motionless during our observation (25 min). As the tree was ca. 8 m from the bridge, we could not capture the lizard, but we did voucher the observation with a digital photograph.

Celestus cyanochloris is considered as "rare and terrestrial, with the tendency to occasionally climb into low bushes" (Savage, *op. cit.*). Our observation suggests that its "rarity" may be a function of previously unrecognized arboreal behavior.

We thank Jay Savage, Matt Williams, Kristen Bell, and Jenny Roberts for useful suggestions on the manuscript. The photograph (MPM Herp Photo 713) was archived in the Milwaukee Public Museum herpetological collection.

Submitted by **ANDRES VAUGHAN**, Universidad de Costa Rica, San Pedro, Costa Rica (e-mail: andresvaughan@hotmail.com); and **JASON BROWN**, Department of Biology, East Carolina University, Greenville, North Carolina, USA (e-mail: JLB0627D2@mail.ecu.edu).

CHAMALELEO JACKSONI (Jackson's Chamaeleon). **ENDOPARASITES.** *Chamaeleo jacksoni* is endemic to east Africa (Spawls et al. 2002. A Field Guide to the Reptiles of East Africa. Academic Press, San Diego, California, 543 pp.). It is now well established in Hawaii due to released pet-trade animals (McKeown 1996. A Field Guide to Reptiles and Amphibians in the Hawaiian Islands. Diamond Head Publishing, Inc. Los Osos, California, 172 pp.). To our knowledge, the only species of helminth known from *C. jacksoni* is the nematode *Oswaldocruzia chamaeleonis* collected from an African specimen (Horchner 1963. Zeit. Parasiten. 22:537–544). The purpose of this note is to report three additional species of endoparasites from Hawaiian *C. jacksoni*.

Thirty-one (9 females, 22 males) *C. jacksoni* (mean SVL = 85 mm ± 20 SD, range: 41–117 mm) collected February 2000 in Honolulu, Oahu, were examined for helminths. Lizards were deposited in the herpetology collection of the Bishop Museum (BPBM), Honolulu as BPBM 13998–14028. The esophagus, stomach, small intestine and large intestine were opened and examined separately for helminths under a dissecting microscope. The body cavity was also searched. Five-hundred seventy-four third-stage nematode larvae (*Physaloptera* sp.) were found in the stomachs of 19 *C. jacksoni*. Prevalence (number infected lizards/number examined x 100) was 61%; mean intensity (mean number nematodes/infected lizards) was 30.2 ± 46.4 SD, range: 1–204. Seven-hundred thirty cysts containing third-stage larvae of *Physocephalus* sp. were found in the stomach wall or body cavity. Prevalence was 61%; mean intensity was 38.4 ± 46.1 SD, range: 1–139. Two cysts containing acuariid larvae were found in the body cavity. Prevalence was 6%; mean intensity was 1. The nematodes are deposited in the United States National Parasite Collection, USNPC, Beltsville, Maryland as *Physaloptera* sp. (94133); *Physocephalus sp.* (94134); acuariid larvae (94135).

Third-stage larvae of species of *Physaloptera* infecting mammals are frequently found in amphibians and reptiles (occurrences summarized in Goldberg et al. (1993. Bull. South. California Acad. Sci. 92:43–51). In Hawaii, *Physaloptera* sp. has been reported in *Hemidactylus frenatus* (Hanley et al. 1998. Oecologia 115:196–205), *Phelsuma guimbeaui, Phelsuma laticauda* (Goldberg et al. 2003. Bishop Mus. Occas. Pap. 74:72–76) and *Anolis equestris* Goldberg et al. (2004. Herpetol. Rev. 35:384–385). Species of *Physocephalus* infect mammals, but encapsulated larvae are commonly found in the tissues of vertebrates that have ingested infected beetles (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission. CABI Publishing, Wallingford, Oxon, UK. 650 pp.). Cysts containing *Physocephalus* sp. have been reported in *Norops sagrei, P. guimbeaui, P. laticauda, H. frenatus, Lepidodactylus lugubris, A. equestris* from

Hawaii (Goldberg and Bursey 2000. J. Parasitol. 86:750–755; Goldberg et al. 2003, *op. cit*; Goldberg et al. 2004, *op. cit.*). Members of the Acuariidae are parasites of terrestrial birds; eggs ingested by insects develop to third-stage infective larvae (Anderson, *op. cit.*). Acuariid larvae have been previously reported from Hawaii in *N. sagrei, P. guimbeaui,* and *P. laticauda* (Goldberg et al. 2002. Amer. Midl. Nat. 148:409–415; Goldberg et al. 2003, *op. cit.).* We know of no reports of larvae of *Physaloptera, Physocephalus,* or the Acuariidae in African chameleons; thus, we consider the occurrence of these species in *C. jacksoni* to represent an instance of an immigrant host capturing local helminths. *Chamaeleo jacksoni* would be a paratenic (= transport host) for these three species.

COLEONYX BREVIS (Texas Banded Gecko). **TAIL REGENERATON**. Reviewing data on caudal regeneration among lizards, Bellairs and Bryant (1985. *In* Gans and Billett [eds.], Biology of the Reptilia, Vol. 15, Development B, pp. 301–410. John Wiley & Sons, New York, New York) noted that the fastest and slowest regeneration rates were 4.7 mm/day for *Lacerta lepida* and 0.07 mm/day for *Anguis fragilis*, respectively. Yet, except for Mulaik (1935. Copeia 1935:155–156), no study has identified the actual rate of tail regeneration in the gecko, *Coleonyx brevis*. Dial and Fitzpatrick (1981. Oecologia 51:310–317) noted that regeneration is rapid, but gave no exact rate. Here we report an unusually rapid rate of tail regeneration in a free-living *C. brevis*, and discuss its significance.

On the night of 30 May 1998, an adult female *C. brevis* was caught in one of a series of 51 19-L pitfall traps deployed near the headquarters of Indio Mountains Research Station, 40 km SW Van Horn, Hudspeth County, Texas (30°46'35"N, 105°00'55"W; elev. 1215 m). Local vegetation consists of Chihuahuan Desert scrub and the trap site was on a gently sloping alluvial fan composed mostly of smaller rock fragments, sand, and silt. This female lizard (62 mm SVL, 2.6 g) had a 13 mm tail with regenerated tip, was not gravid (no developing eggs upon being backlit), was given a single unique toe clip (method of Tinkle 1967. Misc. Publ. Mus. Zool. Univ. Michigan [132]:1–182), and was released near its capture site. On the night of 12 June 1998, this female recaptured in the adjacent pit-fall trap 10 m away, measured 64 mm SVL, weighed 3.4 g and had a completely regrown tail 55 mm long. Again, no egg development was noted. The tail had grown 42 mm in 13 days, a mean of 3.2 mm/day.

This growth rate is 4 times that of the 0.8 mm/day Mulaik (*op. cit.*) described for the first 12 days of his study. In that time, he had a female *C. brevis* regenerate about 33% (or 9.5 mm) of its final total tail length (29.6 mm). Regenerating the total tail length required 68 days. Although not specified therein, Mulaik's (*op. cit.*) study was probably not performed in a natural setting where lizards could optimize feeding and activity periods; thus, the growth rate he recorded may have been constrained. Our female had a tail regeneration growth rate second only to the 4.7 mm/day maximum previously noted for *L. lepida* (Bellairs and Bryant, *op. cit.*). Dial and Fitzpatrick (*op. cit.*) discussed the factors associated with tail regeneration in *C. brevis*, indicating that temperature, reproductive timing, and life expectancy all affect regeneration rate. Briefly, tails are thought to regenerate faster with warmer temperatures and slower during vitellogenesis, and short-lived species, like *C. brevis* (Dial 1975. MS Thesis, Texas A&M University, College Station, Texas. 211 pp.) put more energy into reproduction versus tail regeneration because the probability of future reproductive success is low. However, we expect that the tradeoff between tail regeneration and vitellogenesis would become important only after females become reproductive. Moreover, as energy shunting from tail reserves for reproduction is a pronounced phenomenon in *C. brevis* (Dial and Fitzpatrick, *op. cit.*), we would expect maximal diversion into tail reserves prior to reproductive maturity. The rapid tail regeneration rate we found in our female *C. brevis*, which was pre-vitellogenic, seems consistent with these hypotheses, but examination of regeneration rates between vitellogenic and pre-vitellogenic females will be needed.

Submitted by **JERRY D. JOHNSON**, **G. WALKER JOHNSON**, and **HECTOR RIVEROLL, JR**. Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA; e-mail: (JDJ) jjohnson@utep.edu.

CYCLURA NUBILA LEWISI (Grand Cayman Blue Rock Iguana). **REPRODUCTION.** All published accounts of the reproductive ecology of West Indian Rock Iguanas (genus *Cyclura*) state or imply that these iguanas lay one clutch per year, typically in June or July (Auffenberg 1976. Bahamas Nat. 2:9–16; Carey 1975. Bull. Florida St. Mus., Biol. Sci. 19:189–233; Christian 1986. Caribbean J. Sci. 22:159–164; Grant 1940. Bull. Inst. Jamaica, Sci. Ser. No. 2; Iverson 1979. Bull. Florida St. Mus., Biol. Sci. 24:175–358; Iverson, Hines, and Valiulis, ms. in review; Wiewandt 1977. Ecology, Behaviour, and Management of the Mona Island Ground Iguana, *Cyclura stejnegeri*. Ph.D. dissertation, Cornell Univ., Ithaca, New York, 338 pp.; and seven papers in Alberts [ed.] 2000. West Indian Iguanas: Status Survey and Conservation Action Plan. IUCN, Gland, Switzerland. 111 pp.). With the exceptions of the genus *Brachylophus* (Gibbons and Watkins 1982. *In* Burghardt and Rand [eds.], Iguanas of the World: Their Behavior, Ecology and Conservation, pp. 418–441. Noyes Publ., Park Ridge, New York) and possibly *Dipsosaurus* (Mayhew 1971. Herpetologica 27:57–77), and a reference to possible multiple nesting by *Iguana delicatissima* in Dominica (Day et al. 2000. pp. 62–67 *in* Alberts, *op. cit.*), annual single clutches are reported as the reproductive strategy common to all iguanids (Wiewandt 1982, pp. 119–141 *In* Burghardt and Rand, *op. cit.*). My own observations of released, free roaming captive bred *Cyclura nubila lewisi* observed in the quasi-natural setting of the Queen Elizabeth II Botanic Park on Grand Cayman, Cayman Islands show these iguanas generally match this pattern, mating from late April through May, and laying eggs in June to early July each year.

In 2002 I observed a female *C. n. lewisi* which had then been living in the wild for 2.5 years, mating on 23 June, 21 days after she had laid her eggs. It is unknown whether she nested a second

time that year. The following year I observed the same female laying a clutch of 9 eggs on 24 May, and she nested a second time 53 days later, producing 7 more eggs. A second female laid 10 eggs on 10 June 2003 and nested a second time 60 days later, producing 6 more eggs: this individual had been living in the wild for 3.5 years. Schettino (1999. The Iguanid Lizards of Cuba. Univ. Florida Press, Gainesville, 428 pp.) reported that a captive *C. n. nubila* in Cuba produced two clutches in one year, and the same has occurred with *C. n. nubila* and *C. n. lewisi* in at least three zoos in the United States (J. Lemm, J. Ramer, and A. Verhey, pers. comm.), but these are the first documented cases of biannual nesting in wild *Cyclura*.

Mean turgid egg weight in the first clutches (87.3 g and 105.8 g) was larger than in the second clutches (41.5 g and 66.8 g respectively). All eggs in the first clutches were viable, whereas two in each of the second clutches were incompletely calcified and died early in incubation.

Male *C. n. lewisi* in the wild are frequently seen attempting to copulate with females some time after they have laid eggs, implying that the incidence of biannual reproduction in the population may be significantly greater than is currently recognized. The fact that this has not been observed in wild *Cyclura* before may reflect the paucity of extended observations on individual females rather than rarity of the phenomenon. If incidence of biannual reproduction in *Cyclura* populations is found to be significant, it may require reassessment of life tables and population projections used in conservation management for the taxa concerned, and scheduling duration and seasons for field studies.

EGERNIA STRIOLATA (Tree Skink). **REPRODUCTION**. *Egernia*, a genus of large, long-lived viviparous skinks (Greer 1989. The Biology and Evolution of Australian Lizards. Surrey Beatty & Sons, Sydney. 264 pp.), has reliable litter size estimates for only 13 of the 30 currently described species from Australia (Chapple 2003. Herpetol. Monogr. 17:145–180). Here, we help fill this data gap with litter size information on *Egernia striolata*.

In the first week of January 1999, 14 gravid female *E. striolata* were collected along the South Para River in the Para Wirra Conservation Park (34°68'S, 138°50'E), South Australia, and held in individual 70 x 30 x 30 cm glass tanks maintained at 25°C on a 12:12 photoperiod. Each tank had an overturned box (16 x 16 x 8 cm) for refuge. A 60-W lamp, provided temperatures of 35°C on a basking tile (9 x 9 x 2.5 cm) during the light phase of the photoperiod. Tanks were checked twice daily for the presence of new neonates until 25 February, 2 weeks after the last birth. The 14 females produced 46 young over 23 days (18 January–10 February). Mean litter size was 3.3 (SE 0.2; range: 2–4). Six of the litters were each produced in 1 day, whereas the remaining litters took up to 7 days. The mass and snout–vent length (SVL) of each female was measured on 10 January before parturition (mean mass 45.2 g; SE 1.5; range: 36.8–56.1; mean SVL 112.7 mm; SE 1.1; range: 104–118), and for each neonate on its birth date (mean mass 3.0 g; SE < 0.1; range: 2.3–3.7; mean SVL 50.6 mm; SE 0.2; range: 47–54). Relative clutch mass (RCM), total mass of new born juveniles in the litter as a percentage of the post-parturition mass of the mother, averaged 26.0% (SE 1.0; range: 19.2–31.6). No significant correlations were found between female SVL or mass and average SVL or mass of their offspring. However, longer mothers were significantly heavier ($r = 0.66$; $P = 0.011$), had significantly more young in their litters ($r = 0.71$; $P = 0.004$), had significantly higher total litter mass ($r = 0.78$; $P = 0.001$), and had significantly greater RCM ($r = 0.54$; $P = 0.046$).

Egernia striolata is similar to 14 of 15 other *Egernia* species in timing litter production to the middle of the Austral summer, and is in the middle of the range of RCM values (0.10–0.39) recorded from five other *Egernia* species (Chapple, *op. cit.*). Among *Egernia* species, mean clutch size (range: 2–6) increases with maternal SVL (Chapple, *op. cit.*) and *E. striolata,* with mid-range values for both parameters, also conforms to this pattern.

We thank the Australian Research Council for supporting this research and Douglas Eifler for help in the field. *Egernia striolata* were handled under permit K24117-01 issued to C. M. Bull by the National Parks and Wildlife Service of South Australia.

EULAMPRUS QUOYII (Eastern Water Skink) **PREDATION**. *Eulamprus quoyii* is an opportunistic insectivore also known to eat adult frogs, tadpoles, fish, small skinks (*Ablepharus* sp.) and occasionally carrion (Veron 1969. J. Herpetol. 3:187–189; Daniels 1987. Austral. J. Zool. 35:253–258). Here, I report an observation of predation by *E. quoyii* on one of its sympatric congeners.

On 21 September 2002 at South Mimosa Creek, Blackdown Tableland National Park, central Queensland, Australia (149°04'E, 23°47'S) I caught a female *Eulamprus quoyii* (107 mm SVL, 271 mm tail, 24.5 g) on a cockroach sticky trap baited with live mealworms (*Tenebrio* sp). During handling, the animal regurgitated the two mealworms used as bait and an adult male *Eulamprus sokosoma* (51 mm SVL, 89 mm tail, 3 g). The *E. sokosoma* seemed to have been recently eaten, as minimal digestion appeared to have occurred. Although *Eulamprus* ecology is well studied (e.g., Schwarzkopf 1993. Ecology 74:390–395; Morrison et al. 2002. Molec. Ecol. 11:535–546), this is the first report of interspecific predation within the genus. Both *E. quoyii* and *E. sokosoma* are sympatric in eastern central Queensland, and are also syntopic, as both dwell in rocky habitats. This observation suggests that intrageneric predation may be important for interactions between *Eulamprus* species, and raises the possibility that blood parasites in *Eulamprus quoyii* may be transmitted through predation of sister species (Mackerras 1960. Austral. J. Zool 9:61–134; Smith et al. 1996. Can. J. Zool. 74:1850–1856).

The *Eulamprus sokosoma* specimen has been deposited in the Queensland Museum (QMJ 78447). A Queensland Parks and Wildlife Service Permit (No. F1/000374/00/SAA) was granted to D. J. Salkeld for this work.

EUROLOPHOSAURUS DIVARICATUS (NCN). **DEATH FEIGNING.** Lizards of the subfamily Tropidurinae are common members of South America fauna (Frost 1992. Amer. Mus. Novit. 3033:1–68), exploiting a variety of habitats (Kohlsdorf et al. 2001. J. Morphol. 248:151–164). In general, Tropidurinae (*sensu stricto*) are heliothermic, territorial, sit-and-wait predators that thermoregulate behaviorally (Rodrigues 1988. *In* Heyer and Vanzolini [eds.], Proceedings of a Workshop on Neotropical Distribution Patterns, pp. 305–315. Academia Brasileira de Ciências, Rio de Janeiro). *Eurolophosaurus divaricatus*, a medium-sized (to 92 mm SVL) Brazilian species found west of Rio São Francisco, Estado da Bahia, Brazil (Rodrigues 1986. Papéis Avulsos de Zoologia, São Paulo 36:171–179), is common on dunes. This species typically relies on sprint speed to escape predators and attempts to reach nearby concealing vegetation or dives into sand when threatened (Rodrigues 1986, *op. cit.*). Presumptive death-feigning behavior in *E. divaricatus* behavior was first observed by one of us (MTR) on collecting trips, but this behavior is unstudied in this species. Here, we describe behavioral observations and experiments on *E. divaricatus* intended to provide insights into this behavior.

Our observations were based on two adult males and two females *E. divaricatus* collected at Alagoado, Estado da Bahia, Brazil (09°29'01"S, 41°22'21"W). Lizards were maintained for two weeks in large plastic boxes (50 x 70 x 40 cm) provided with infrared heating lamps and a vermiculite substrate. We confirmed death feigning in the lab when we first manipulated animals. Over the time interval 1000–1700 h when observations and tests were performed, animals were alert and ready to respond to observer approach. Upon capture, they sometimes struggled and attempted to bite. Struggle, however, ceased very quickly and was followed by relaxation of body, tail and limbs, closing of eyelids (Fig. 1) and deep slow ventilatory movements. This behavior continued even if lizards were released and placed upside down on the boxes. After less than three minutes the lizards recovered and quickly attempted to flee.

We manipulated animals at temperatures of 14, 24, and 42°C to explore whether thermal conditions might alter death feigning. The highest experimental temperature is probably close to field activity temperatures, as these thermophilic lizards select high temperatures in a thermal gradient day or night (day: mean = 36.1°C ± 2.11°C; night: mean = 37.9°C ± 0.56°C; overall range of temperatures selected: 25.6–44.3°C). In their dune habitat, substrate temperatures may reach 60°C between 1300 and 1500 h (Rocha 1998. PhD Dissertation, Depto. de Zoologia, Universidade de São Paulo, Brazil. 108 pp.). After maintaining each individual in a cloth bag at the experimental temperature for 40 min, we seized each lizard firmly by the neck. We recorded the time when death feigning was first performed and measured the animal's cloacal temperature at that time. We randomized the test temperature order and each animal was tested 6 times at each temperature, with intervals of 1 hour between tests.

Death feigning consistently occurred within 2 min following hand capture, and was not necessarily preceded by a struggle. Three individuals feigned death at all three experimental temperatures, but the largest male death-feigned only at 14 and 24°C, although it did not behave aggressively when not feigning death at high temperature. We did not detect differences among individuals either in the lag time to death feigning or temperature (lag time: $F_{3,24}$ = 2.2, P = 0.113; temperature: $F_{1,24}$ = 3.2, P = 0.087). The lag time to death feigning averaged 27 sec (SD = 19 sec; range: 10–96 sec). Death feigning was less frequent at 42°C, but differences were not significant and the result was due to only one animal (c^2 = 5.4, P = 0.067). However, we observed that animals habituated to manipulation so that they exhibited death feigning responses less often after a few days of captivity and manipulation.

Our data suggest that this behavior is analogous to the death feigning observed in other squamates (e.g., Burghardt and Greene 1988. Anim. Behav. 36:1842–1844; Mutoh 1983. Herpetologica 39:78–80). Some species have evolved complicated death feigning behaviors that apparently improve their chances of survival after predator attacks (Schieffelin and de Queiroz 1991. Herpetologica 47:230–237). Among lizards, the most common antipredator behavior is running (Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, vol. 16, pp. 1–52. Alan R. Liss, Inc., New York, New York), but at cold temperatures, when it may be difficult to outrun a predator, some species switch to aggressive behavior such as biting (Hertz et al. 1982. Anim. Behav. 30:676–679). In contrast, death feigning, although generally rare in lizards, may be common in the genus *Eurolophossaurus*. Anecdotal observations suggest that the other two members of this group, *E. amathites* and *E. nanuzae*, exhibit similar death-feigning behavior (MTR, pers. obs.). These observations are interesting because *E. amathites* is the sister species of *E. divaricatus* (Frost et al. 2001. Mol. Phyl. Evol. 21:352–371), and also a dune dweller, but found on the east side of the Rio São Francisco (MTU, pers. comm.). In contrast, *E. nanuzae* is a saxicolous species from campos rupestres in Central Brazil (Rodrigues 1981. Papéis Avulsos de Zoologia, São Paulo 34:145–149).

One could hypothesize that the apparent death-feigning we report is actually a manifestation of stress or exhaustion. However, given that most Tropidurinae do not exhibit such behavior under similar conditions, and that struggling was not a necessary precursor to death feigning, we suggest that the apparent feigning we observed in *E. divaricatus* is ecologically meaningful and related to an escape strategy in free-ranging lizards. This behavior may have evolved in response to predators that do not immediately consume captured prey. The main predators of *E. divaricatus* are *Didelphis albiventris* (a skunk), small hawks, and snakes like *Philodryas nattereri*, *P. offersi*, and *Oxyrhopus trigeminus* (MTR, pers. obs.). Some of these predators frequently wait before eating their prey because they go back to their nests or alternate attention between prey and their surroundings (MTR, pers. obs.). Thus, immobility followed by quick recovery and fleeing may allow these lizards to evade some predators. Field and laboratory tests of this hypothesis will be necessary to understand the functional significance of death feigning in *Eurolophosaurus*.

Financial support came from FAPESP grants to C. A. Navas (95/9378-6) and M. T Rodrigues (96/3554-0), and a FAPESP doctoral fellowship (00/06662-5) to T. Kohlsdorf. We thank C. Jared for the photograph, and C. Bevier for valuable comments on the manuscript. IBAMA-Brazil grants the collecting permit.

FEYLINIA ELEGANS (Elegant Feylinia). **ENDOPARASITES.** *Feylinia elegans* (Scincidae) occurs in Angola, Congo, Gabon, Uganda, and Zaire (Welch 1982. Herpetology of Africa, Krieger Publishing Company, Malabar, Florida. 293 pp.). To our knowledge, this is the first report of helminths from *F. elegans*.

One adult male (105 mm SVL) *F. elegans* (MCN 940) from the Museo de Ciencias Naturales de la Universidad Nacional de Salta, Salta, Provincia de Salta, Argentina that R. F. Laurent collected in Omaniundu (3°21'S, 23°16'E), Republic of the Congo, Africa, on 18 August 1959 was examined. It was fixed in 10% formalin then preserved in 70% ethanol. The abdominal cavity was opened, the gastrointestinal tract removed, slit longitudinally, and examined under a dissecting microscope. Helminths were removed to a drop of undiluted glycerol for identification.

One species of Nematoda, *Africana africana* (Heterakidae) was found in the stomach. The 2 female, 2 male *A. africana* specimens were placed in a vial of 70% ethanol and deposited in the collection of the Fundación Miguel Lillo (FML 01782), San Miguel de Tucumán, Provincia de Tucumán, Argentina.

Hosts of *A. africana* include *Chamaeleo cristatus* of Cameroon (Rasheed 1965. J. Helminthol. 39:67–100), *C. gracilis* of Republic of the Congo (Baylis 1939. Ann. Mag. Nat. Hist. Ser.11. 3:625–629), *Kinixys belliana* of Guinea (Gendre 1909. Actes Soc. Linn. Bordeaux 63:33–41) and Malawi (Fitzsimmons 1961. Ann. Parasit. Hum. Comp. 36:107–112), *K. erosa* of Republic of the Congo (Baylis 1940. Ann. Mag. Nat. Hist. Ser. 11. 5:401–416), *Varanus griseus* of Benin (Gendre 1911. Actes Soc. Linn. Bordeaux 65:68–78), and *V. niloticus* of Republic of the Congo (Graber 1981. Rev. Elev. Med. Vet. Pays Trop. 34:155–167). The life history of *A. africana* apparently has not been studied, but other heterakoids are monoxenous (no intermediate host); eggs containing the infective stage are ingested by the host (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission 2nd ed. CABI Publishing, Oxon, UK. 650 pp.). *Feylina elegans* represents a new host record for *A. africana*.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). **COMMUNAL NESTING.** *Hemidactylus mabouia* is an exotic gekkonid presumably introduced via slave ships to Brazil (Vanzolini 1978. Papéis Avulsos Zool., S. Paulo 31:307–343). *H mabouia*, like many other gekkonids, consistently produces two eggs per clutch (Vitt 1986. Copeia 1986:773–786). Although communal nesting is known for a number of gekkonids (Flower 1933. Proc. Zool. Soc. London 1933:735–851; Bustard 1967. Herpetologica 23:276–284; Shanbhag 1999. Herpetol. Rev. 30:166), it has not been reported in *H. mabouia*. Here, we report on oviposition in *H. mabouia* from southern Brazil that suggests communal nesting.

On 27 March 2003, we collected 10 *H. mabouia* eggs on a ca. 50 x 30 cm piece of granite in urban environment in neighborhood to the Parque Jardim Botânico de Porto Alegre (30°04'S, 51°11'W; elev. 47 m), Rio Grande do Sul. The eggs were incubated in vermiculite. The mean volume of the eggs was 472.0 cm^3 (SD = 85.8), and the mean mass was 0.4 g (SD = 0.2). One hatchling emerged on each of 27 and 30 April; 14 May; 25, 27 and 30 June and 9 July. Two eggs did not hatch. The staggered pattern of hatching implies that at least four clutches were represented. Individuals that hatched were released at the location where the eggs were found.

Porto Alegre, Rio Grande do Sul, Brazil; e-mail (RLB): rbalestrin@pucrs.br.

HEMIDACTYLUS (House Geckos). **ANTI-PREDATOR BEHAVIOR.** Florida, which has experienced a dramatic influx of exotic lizards, now has more non-indigenous than native species (Butterfield et al. 1997. *In* Simberloff et al. [eds.], Strangers in Paradise: Impact and Management of Nonindigenous Species in Florida, pp. 123–138. Island Press, Washington, D.C.). Many of these exotics have remained near their points of initial arrival, but three *Hemidactylus* geckos (*Hemidactylus garnotii*, *H. mabouia*, and *H. turcicus*) have substantially expanded their ranges (Butterfield et al., *op. cit.*). All three species appear to occupy similar niches, being found largely on buildings with external lights. *Hemidactylus turcicus*, native to the Mediterranean, northern Africa, and southwest Asia (Henkel and Schmidt 1995. Geckoes: Biology, Husbandry, and Reproduction, Krieger Publishing Company, Malabar, Florida. 237 pp.), has been recorded in Florida since ca. 1915 (Butterfield et al. 1997, *op. cit.*). *Hemidactylus garnotii*, a parthenogenetic form from southeast Asia and the Pacific region (Kluge and Eckhardt 1969. Copeia 1969:651–664), probably arrived in Florida around 1963 (Butterfield et al., *op. cit.*). Most authors suggest a southern African origin for *Hemidactylus mabouia* (Powell et al. 1998. Cat. Amer. Amphib. Rept. 674:1–11), which was first recorded in Florida in 1991 (Lawson et al. 1991. Herpetol. Rev. 22:11–12) and has been spreading rapidly in mainland Florida (Butterfield et al. 1993. Herpetol. Rev. 24:111–112; Meshaka et al. 1994. Herpetol. Rev. 25:80–81). In southern Florida, reduction in *H. turcicus* populations seem to correspond to the increased presence of congeners (Meshaka et al., *op. cit.*). *Hemidactylus mabouia* has been documented replacing *H. garnotii* (Meshaka and Moody 1996. Florida Sci. 59:115–117), so that *H. mabouia* seems to be currently expanding its range as the other two species are contracting in distribution. In an effort to identify mechanisms that may contribute to the patterns of range expansion and species replacement among these geckos, we undertook a study to compare their anti-predator

behaviors.

During 11–17 March 2000, we surveyed geckos on 55 buildings within Brevard, Okeechobee, Highlands, and Orange counties, Florida. On 52 buildings, only one species was found. Two species were recorded on two buildings. All three species were observed on one building. Surveys were generally conducted in the interval 2015–0115 h. Twenty-eight of the buildings were hotels; the remainder were non-residential structures (banks, churches, stores, and restaurants) that had some kind of external lighting. All but two of the buildings had their exterior lights on during surveys.

At each building, pairs of observers walked the perimeter searching for geckos. When a gecko was sighted, one observer approached the building at a slow steady pace and, upon reaching the wall, attempted to manually catch the lizard. We kept approach speed uniform (ca. 0.25 m/sec) among observers. The second observer remained back from the building, and recorded anti-predator responses: 1) approach distance (A_d) - the distance (cm) between the approaching observer and the gecko, when the latter first fled, and 2) flight distance (F_d) - the distance (cm) the gecko moved on its first escape attempt after being approached. An A_d of 0 was assigned to geckos who allowed observers to reach the wall before fleeing. An F_d of 0 was assigned to geckos who did not flee before the observer reached the wall. Sample sizes for F_d were smaller than for A_d. It was not always possible to see where a flight ended. For geckos that were captured, we recorded whether they tried to bite as a defense, as well as their snout-to-vent length (SVL, mm).

We used nonparametric statistics for analyses. Statistical significance was assigned using an initial rejection criterion of < 0.05. We adjusted for multiple tests using the sequential Bonferroni method (Sokal and Rohlf 1995. Biometry 3rd edition, W. H. Freeman and Company, New York. 887 pp.). All tests were performed using Minitab (3801 Enterprise Drive, State College, Pennsylvania).

Both A_d and F_d varied significantly among the three species (Kruskal-Wallis: H = 15.3, df = 2, $P < 0.001$; H = 13.41, df = 2, $P = 0.001$ respectively). *Hemidactylus mabouia* allowed the closest approach, with the median A_d being 0 cm (range 0–475 cm, N = 63) and had the shortest F_d (median = 5 cm, range 0–130 cm, N = 54). *Hemidactylus garnotii* had the longest A_d (median = 106 cm, range 0–460 cm, N = 42), and a median F_d of 25 cm (range 0–420, N = 39). *Hemidactylus turcicus* displayed a median A_d of 50 cm (range 0–500 cm, N = 19), and F_d of 27 cm (range 0–125 cm, N = 14). Post hoc comparison revealed that the A_d for *H. mabouia* was significantly shorter than that for both *H. garnotti* (Mann Whitney: $P = 0.0003$) and *H. turcicus* (Mann Whitney: $P = 0.044$), whereas A_d did not differ significantly between *H. turcicus* and *H. garnotti* (Mann Whitney: $P = 0.36$). Post hoc comparison also revealed that the F_d for *H. mabouia* was significantly shorter than that for both *H. garnotti* (Mann Whitney: $P = 0.0015$) and *H. turcicus* (Mann Whitney: $P = 0.012$), but F_d did not differ significantly between *H. turcicus* and *H. garnotti* (Mann Whitney: $P = 0.78$).

Approach distance was unrelated to F_d for both *H. garnotii* and *H. turcicus* ($F_{1,34} = 0.0$, $P = 0.95$; $F_{1,12} = 0.8$, $P = 0.38$, respectively), but a significant but weak positive relationship existed between A_d and F_d for *H. mabouia* ($F_{1,51} = 9.25$, $r^2 = 15.4$, $P = 0.004$; $F_d = 7.73 + 0.095\,A_d$). Body size was unrelated to either A_d or F_d in any of the species (Approach Distance: *H. garnotii*: $F_{1,26} = 0.08$, $P = 0.78$; *H. turcicus*: $F_{1,14} = 1.57$, $P = 0.23$; *H. mabouia*: $F_{1,45} = 0.53$, $P = 0.47$; Flight Distance: *H. garnotii*: $F_{1,23} = 1.16$, $P = 0.29$; *H. turcicus*: $F_{1,10} = 0.01$, $P = 0.91$; *H. mabouia*: $F_{1,36} = 2.10$, $P = 0.15$).

Upon capture, interspecific differences existed in the likelihood of using biting as a defense (Chi-square: $c^2 = 27.5$, df = 2, $P < 0.001$). *Hemidactylus mabouia* was much more likely to bite than the other two species. *Hemidactylus mabouia* attempted to bite during 55% of captures (N = 47). Only 5% of captured *H. garnotii* (N = 38) and 16% of *H. turcicus* (N = 19) tried to bite. We observed no indication that the animals that avoided capture were likely to behave differently than the captured geckos. In addition, biting by *H. mabouia* was significantly related to body size; biting individuals (median SVL = 57 mm) were significantly larger than non-biting individuals (median SVL = 41; Mann-Whitney: U = 422, N = 27, 22; $P = 0.01$).

The more aggressive and less flighty behavior we quantified in *H. mabouia* may help explain why this species is expanding its range, while the other two species are contracting in distribution. *Hemidactylus mabouia* may be behaviorally dominant to the other two species. In addition, the tendency of *H. mabouia* to remain stationary upon approach may make it an effective predator of juvenile *H. garnotti* and *H. turcicus*. As behavioral dominance is a documented mechanism contributing to species displacement in some gecko assemblages (Petren et al. 1993. Science 259:354–358; Petren and Case 1996. Ecology 77:118–132), and predation by *H. mabouia* on hemidactyline geckos has been documented (Meshaka 2000. J. Herpetol. 34:163–168), further tests of these hypotheses is warranted.

Our thanks to the University of Wisconsin–Stevens Point for funding, Maria Eifler for assistance in the planning of the study and comments on the manuscript, and Louisa Kerwin for making housing and facilities available at the Riverwoods Field Laboratory.

LEIOCEPHALUS CARINATUS CORYI (NCN). **NEST LOCATION.** Although among the most conspicuous lizards in the West Indies, curly-tailed lizards (*Leiocephalus* spp.) have few published accounts of their nesting behavior. Smith and Iverson (1993. Can. J. Sci. 71:2147–2151) describe one nesting episode for *L. psammodromus,* where the eggs were deposited ca. 5 cm deep in sand at the base of a small shrub (*Borrichia arborescens*). Here, we report the first observation of the use of a termite mound for nesting by *L. carinatus coryi.*

On 16 August 2003, we discovered two *L. carinatus coryi* eggs adjacent to an active *Nasutitermes rippertii* termite mound during excavation of an Andros Iguana (*Cyclura cychlura cychlura*) nest on Sandy Cay, South Andros, Bahamas (24°05'24"N, 77°41'44"W; elev. 1.5 m). Both *Leiocephalus* eggs were buried in a uni-directional skirt of loose termite carton with mixed loam and leaf litter. The eggs were directly in front of a tunnel entrance excavated and filled by a female iguana on 13 June 2003. The eggs were

deposited at the base of the mound ca. 3 cm in front of the entrance with ca. 5 cm of carton covering them. At the time of excavation, one of the eggs (25.2 x 12.2 mm) was flaccid and appeared lifeless, whereas the other (24.9 mm x 14.2 mm) appeared viable. Egg sizes closely match those Schwartz and Henderson reported (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Press of Florida. 720 pp.; i.e., 25.1 x 11.5 mm), and two appears to be the typical clutch size for the genus (Smith and Iverson, *op. cit.*; Nelson et al. 2001. Contemp. Herpetol. http://www.cnah.org/ch/ch/2001/1/index.htm). We tried to incubate the eggs in a plastic container filled with termitaria carton, but aborted incubation after two days when it was clear that the eggs were lifeless. The embryo in the flaccid egg was slightly less developed than the other, but both embryos were clearly identifiable as *L. carinatus coryi;* the better developed specimen was deposited in the Florida Museum of Natural History (UF 138902). We estimated the clutch to be a maximum of 64 days old based on our 13 June 2003 observation of oviposition by the female *C. c. cychlura* in the same mound.

South Andros offers little vertical relief and has a substrate composed of jagged karst limestone with scant soil accumulation. The island has a distinct wet season from May to October when high water often results in a raised water table toward the limestone surface. Ovipositing in the loose termitaria media accumulated by nesting female iguanas may be advantageous for *L. carinatus coryi* because mounds are elevated above flood level and remain dry throughout the rainy season. Additionally, the soft, soil-like carton offered by using termitaria, and the constant temperature created by the adjacent termite colony, may provide a convenient incubation site in an environment with little soil and moderately fluctuating temperatures (Magnusson et al. 1985. J. Herpetol. 19:199–207).

We thank the Bahamas Department of Agriculture for permission to conduct our research and for issuing permits, and Ken Dodd for comments on the manuscript.

Shedd Aquarium, Chicago, Illinois 60605, USA, and Department of Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA (e-mail: cknapp@ufl.edu).

LIALIS BURTONIS (Burton's Snake Lizard). **ENDOPARASITES.** *Lialis burtonis* (Pygopodidae) occurs throughout continental Australia and parts of New Guinea (Cogger 2000. Reptiles and Amphibians of Australia. 6th ed. Ralph Curtis Books, Sanibel Island, Florida, 808 pp.). Previous reports of endoparasites of *Lialis burtonis* include the cestode *Kapsulotaenia tidswelli* (Johnston 1914. Proc. Roy. Soc. Queensland 26:76–84), physalopterid larvae (Jones 1995. J. Wildl. Dis. 31:299–306), and the acanthocephalan *Porrorchis hylae* (Bolette 1996. J. Wildl. Dis. 32:704–706). The purpose of this note is to add an additional nematode to the host list of *L. burtonis.*

We examined one adult (152 mm SVL) female *Lialis burtonis* (FML 06515) from the Herpetological Collection of Fundación Miguel Lillo, San Miguel de Tucumán, Argentina that Simon Oliver collected in Queensland, Australia, 29 March 1993. It had been fixed in 10% formalin and preserved in 70% ethanol. The abdominal cavity was opened, the gastrointestinal tract removed, slit longitudinally, and examined under a dissecting microscope. Helminths were removed to a drop of undiluted glycerol for identification.

One species of Nematoda, *Ophidascaris pyrrhus* (Ascarididae) was found in the stomach. The 3 female, 3 male specimens were placed in a vial of 70% ethanol and deposited in the collection of the Fundación Miguel Lillo (CHFML 07417).

Ophidascaris pyrrhus was originally described from the snake *Pseudechis porphyriacus* collected in New South Wales, Australia (Johnston and Mawson 1942. Rec. Aust. Mus. 21:110–115) and subsequently reported from the snakes *Denisonia punctata, Echiopsis curta, Notechis ater, Pseudechis australis, Pseudonaja nuchalis, P. textilis,* and *P. modesta* from western Australia (Jones 1980. Aust. J. Zool. 28:423–433). The life history of *O. pyrrhus* apparently has not been studied, but other ophidascarids have been found to require an amphibian or mammal intermediate host (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission. 2nd ed. CABI Publishing, Oxon, UK. 650 pp.). *Lialis burtonis* represents a new host record for *Ophidascaris pyrrhus.*

MABUYA LONGICAUDATA (Long-tailed Skink). **PREDATION**. Of the four species of the near-pantropical skink genus *Mabuya* that inhabit Taiwan, *M. longicaudata* inhabits lowland areas (< 500 m elev.) in central and southern Taiwan (Lue et al. 2002. The Transition World - Guidebook of Amphibians and Reptiles of Taiwan. SWAN, Taipei, 145 pp. [In Chinese]; Shang and Lin 2001. Natural Portraits of Lizards of Taiwan. Big Trees Publishers, Taipei, 80 pp. [In Chinese]). Here, we report observations relating to predation by *M. longicaudata* on Brown Anoles (*Anolis sagrei*), a species introduced to Taiwan (Norval et al. 2002. Zoological Studies 41:332–336).

At 1018 h on 15 March 2001, a *M. longicaudata* (ca. 120 mm SVL) was observed basking on a piece of black plastic along an irrigation ditch in an agricultural area of Santzepu, Shuisan District, Chiayi County, Taiwan (23°25'45"N, 120°28'59"E). The weather was partially overcast (air temperature = 25.2°C). A young *A. sagrei* (ca. 35 mm SVL, sex undetermined) approached the basking skink. When the *Anolis* was ca. 30 cm away from the *Mabuya*, the skink dashed towards the anole, seizing it by the head. With the neck clamped in the skink's jaws, the anole's body protruded from the left side of the skink's mouth. The anole was held in this position until it stopped struggling. The skink then moved to nearby vegetation where it swallowed the anole.

At 1005 on 27 March 2001, a smaller skink (ca. 85 mm SVL) was seen in the same area attempting to capture another small (ca.

30 mm SVL) Brown Anole at the base of a 17.5-cm diameter Betel Palm (*Areca catechu*). Weather was sunny (air temp. = 27.7°C). When first observed, the skink was ca. 40 cm from the anole. Almost immediately the anole spotted the skink and fled up the trunk of the palm, whereupon the skink discontinued the chase.

As the diet and feeding behavior of *M. longicaudata* is poorly understood, it is not known whether predation on other lizards is common. Cooper and Whiting (2000. Copeia 2000:112–118) reported ambush foraging in *Mabuya acutilabris* and *M. spilogaster*, as well as active foraging in *M. striata sparsa*, *M. sulcata*, and *M. variegata*. Our foraging observations of *M. longicaudata* resemble ambush foraging in the first case and active foraging in the second.

NOROPS CUPREUS (Copper Anole). **ENDOPARASITES.** *Norops cupreus* occurs in a wide variety of habitats in Costa Rica and Nicaragua (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas, University of Chicago Press, Chicago, 934 pp.). To our knowledge, no reports exist of endoparasites from this species. The purpose of this note is to report the presence of two nematode species in *N. cupreus* from Costa Rica.

Ten (4 females, 6 males) *N. cupreus* (mean SVL = 41 mm ± 4 SD, range: 33–45 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles (California, USA): LACM 146707–708, 146710, 146716–146721, 146723 collected in San José and Guanacaste Provinces, Costa Rica in 1973 and 1996, respectively were examined for helminths. The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The body cavity was also searched. Three *Physaloptera retusa* were found in the stomach of LACM 146719 and one *Physocephalus* sp. (larva in cyst) was found in the stomach wall of LACM 146721. Both infected anoles were from Guanacaste Province. Prevalence (infected lizard/lizards examined x 100) was 10% for each nematode species. The nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as *Physaloptera retusa* (USNPC 93678) and *Physocephalus* sp. (USNPC 93679).

Physaloptera retusa is known in a variety of lizards from the Western Hemisphere (Goldberg et al., Comp. Parasitol. *in press*). Various insects serve as intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, 2nd ed., CABI Publishing, Wallingford, Oxon, UK. 650 pp.). *Norops cupreus* represents a new host record for *P. retusa*. Costa Rica is a new locality record. Encapsulated larvae of *Physocephalus* commonly occur in gut tissues of terrestrial vertebrates which have ingested infected dung beetles; no further development occurs (Anderson, *op. cit.*). *Norops cupreus* represents a new host record for *Physocephalus* sp. but is most likely only a paratenic (transport) host. Costa Rica is a new locality record for *Physocephalus*.

PETROSAURUS REPENS (Central Baja California Banded Rock Lizard). **SCALE VARIATION**. According to Grismer (2002. Amphibians and Reptiles of Baja California including its Pacific Islands in the Sea of Cortés. University of California Press, Berkeley, California. 399 pp.), possession of a postorbital stripe and one scale between the nasal and supralabials is diagnostic for the rock lizard species, *Petrosaurus repens*. In contrast, its congener, *P. thalassinus*, lacks the stripe and presents two scales between the nasal and supralabials. Here, we report the occurrence of a *P. repens* with the nasal scale morphology of *P. thalassinus*.

At 1100 h on June 15 2003, one of us (OHG) collected a young female *P. repens* (69.4 mm SVL) near Santa Rosalia, Baja California Sur, México (27°11'17"N, 112°14'41"W; elev. 541 m). This specimen, collected next to a microwave station in rocky desert scrub habitat, had the postorbital stripe characteristic of *P. repens* and was found at least 350 km (straight line distance) outside of the range where *P. thalassinus* has been recorded (Grismer, *op. cit.*). However, this specimen has two scales between the nasal and supralabials (Fig. 1). This find suggests caution regarding field diagnosis of the species of *Petrosaurus* exclusively relying on scale morphology in the nasal region.

The specimen, the identity of which was verified by L.Grismer, was deposited in the Colección Nacional de Anfibios y Reptiles, Instituto de Biología, UNAM (IBH-14608). We thank L. Grismer for the verification and reading a draft of this note.

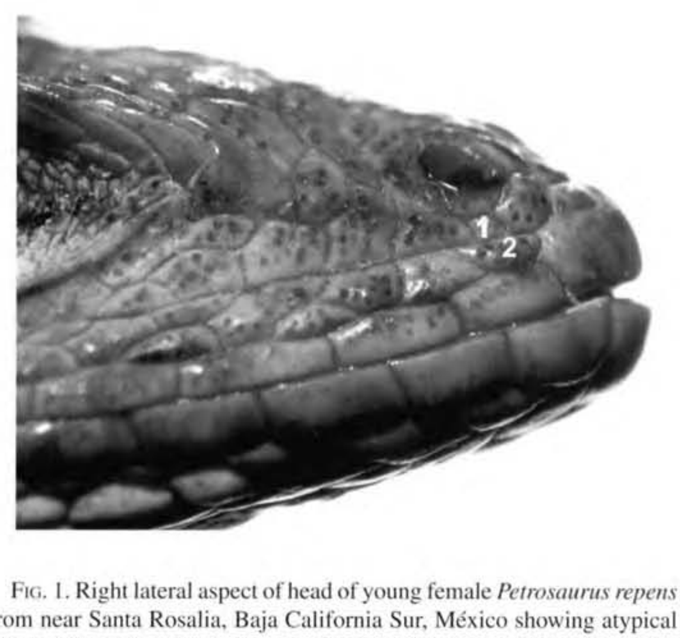

FIG. 1. Right lateral aspect of head of young female *Petrosaurus repens* from near Santa Rosalia, Baja California Sur, México showing atypical nasal scale morphology. Numbers indicate the two scales between the nasals and supralabials.

PHYLLODACTYLUS REISSII (Peter's Leaf-toed Gecko). **ENDOPARASITES.** *Phyllodactylus reissii* is known from coastal Ecuador and Peru (Peters and Orejas-Miranda 1986. Catalogue of the Neotropical Squamata. Part II Lizards and Amphisbaenians. Smithsonian Institution Press, Washington, D.C. 293 pp.). To our knowledge, no reports exist of its endoparasites. The purpose of this note is to report two species of Nematoda from *P. reissii.*

Ten (8 females, 2 males) *P. reissii* (mean SVL = 58 mm ± 5 SD, range: 49–67 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA (LACM 123091, 123093–123095, 123097–098, 123117, 123119–123121) were examined for helminths. Geckos were collected in Lambayeque Department, Peru during May–June 1976. The esophagus, stomach, small and large intestines were opened and separately searched for helminths under a dissecting microscope. The body cavity was also examined for helminths. Found were two species of nematodes: in the large intestines, adults of *Spauligodon oxkutzcabiensis* prevalence (infected lizards/lizards examined x 100) = 80%; mean intensity ± 1 SD (mean number nematodes per infected lizard) = 68 ± 42, range: 13–128; in the stomach, one third-stage larva of an unidentified species of *Physaloptera,* prevalence 10%. The nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as *Spauligodon oxkutzcabiensis* (USNPC 94032) and *Physaloptera* sp. (USNPC 94033).

Spauligodon oxkutzcabiensis was described from *Thecadactylus rapicauda* from the Yucatan, Mexico (Chitwood 1938. Publ. Carnegie Inst. Washington 491:51–66). It has also been found in sceloporine lizards (*Sceloporus malachiticus*) from Costa Rica (Goldberg 1992. J. Helminth. Soc. Washington 59:125–126) and (*S. formosus, S. grammicus, S. megalepidurus, S. mucronatus*) from Mexico (Goldberg et al. 2003. Southwest. Nat. 48:208–217). Third-stage larvae of *Physaloptera* sp. (adults absent) are commonly found in amphibians and reptiles. Their occurrences were summarized in Goldberg et al. (1993. Bull. South. California Acad. Sci. 92:43–51). *Phyllodactylus reissii* represents new host records for *S. oxkutzcabiensis* and *Physaloptera* sp.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu), and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania, USA (e-mail: cxb13@psu.edu).

PHYLLODACTYLUS TUBERCULOSUS (Yellow-bellied Gecko). **ENDOPARASITES.** *Phyllodactylus tuberculosus* occurs from central Sonora, Mexico to central Costa Rica (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). To our knowledge, no reports exist of its endoparasites. The purpose of this note is to report one species of Nematoda from *P. tuberculosus.*

Ten (5 females, 5 males) *P. tuberculosus* (mean SVL = 64 mm ± 6 SD, range: 58–78 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA (LACM 93818, 19821, 93826, 93828–93830, 93832, 93833, 93838, 93846) were examined for helminths. Geckos were collected in Sonora, Mexico during 1961–1964. The esophagus, stomach, small and large intestines were opened and searched for helminths under a dissecting microscope. The body cavity was also examined for helminths. Found in the large intestines was one species of Nematoda, *Spauligodon giganticus*; prevalence (infected lizards/lizards examined x 100) = 80%; mean intensity ± 1 SD (mean number nematodes per infected lizard) = 19 ± 8, range: 9–32. The nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as *Spauligodon giganticus* (USNPC 94034).

Spauligodon giganticus was described from *Sceloporus graciosus* by Read and Amrein (1953. J. Parasitol. 39:365–370). It is a widespread nematode that occurs in a variety of lizards both in the United States and Mexico (Bursey and Goldberg 1992. Amer. Midl. Nat. 127:204–207; Goldberg et al. 1996. Amer. Midl. Nat. 135:299–309; Goldberg et al. 2002. Texas J. Sci. 54:282–285; Goldberg et al. 2003. Southwest. Nat. 48:208–217). *Phyllodactylus tuberculosus* is a new host record for *S. giganticus.*

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania, USA (e-mail: cxb13@psu.edu).

PHYLLOPEZUS POLLICARIS (Rock Gecko). **CLUTCH SIZE AND OVIPOSITION SITES.** Knowledge of the reproductive ecology and life history of Brazilian lizards has expanded enormously during the last decade. However, Brazilian geckos have generally remained less studied. Vitt (1986. Copeia 1986:775–786) conducted a quantitative study of four gecko species from northeastern Brazil that included data on *Phyllopezus pollicaris.* Here, we add data on clutch size and oviposition sites for *P. pollicaris* from southeastern Brazil.

During a survey on 2–3 January 2003, we found five groups of eggs of *P. pollicaris* in the municipality of Diamantina (18°14'S, 43°36'W; elev. 1113 m), Estado de Minas Gerais, in the Espinhaço Mountains. The habitat consists of vegetation typical of rocky substrates, termed "campos rupestres," with a predominance of the families Eriocaulaceae, Velloziaceae, and Melastomataceae. The eggs had calcified shells, a characteristic of many gekkonids (Packard et al. 1982. Herpetologica 38:136–155), and were glued to each other as well as to furrows in the rock (we were not able to measure the eggs as we avoided disturbing them). The highly calcified shell and egg microhabitat excluded sympatric teiids, *Ameiva ameiva* and *Kentropyx paulensis,* and tropidurids, *Eurolophosaurus nanuzae* and *Tropidurus montanus.* Egg shape and dimensions excluded the sympatric gecko, *Gymnodactylus guttulatus*, which has smaller eggs with a more spherical shape (unpubl. data). Clutches of *Phyllopezus pollicaris* were exposed to the environment in furrows ca. 4 cm deep on rock surfaces and

found at heights 0.8–4.5 m above ground (mean = 1.96 m ± 1.49). Number of eggs grouped together varied from 2 to 10 (mean = 6.4 ± 4.1).

Gekkonids have small clutches (Sinervo 1994. *In* Vitt and Pianka [eds.], Lizard Ecology, pp. 73–90. Princeton University Press, New Jersey; Dunham and Miles 1985. Amer. Nat. 126:231–257), typically depositing only one or two eggs. The number of eggs on three of the oviposition sites (two with 10 and one with 8) agrees with the finding of Vitt (*op. cit.*) that this species oviposits communally; he found that 1–3 female *P. pollicaris* deposited eggs at oviposition sites in northeastern Brazil. Our data imply that a minimum of 4–5 females comprised the communal clutches we observed in the Diamantina population.

We thank Marc P. Hayes for offering helpful suggestions on previous versions of this manuscript. This work was completed while CABG was supported by a graduate fellowship from Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES).

SCELOPORUS MAGISTER UNIFORMIS (Yellow-backed Spiny Lizard). **FAILED PREDATION**. Few passerine birds are large enough to prey on small vertebrates, shrikes (Passeriformes: Laniidae) are prominent among them. Shrikes kill with blows of their bills to the head or backbone and usually impale their prey on plant thorns or spines or other sharp objects (e.g., barbed wire) for later consumption (Elphick et al. [eds.] 2001. The Silbey Guide to Bird Life & Behavior. Alfred A. Knopf, Inc. New York. 407 pp.). Numerous records exist of squamates as prey of Loggerhead Shrikes (*Lanius ludovicianus*), but most represent relatively small (< 15 g) prey (Miller in Bent 1950. *In* Life Histories of North American Wagtails, Shrikes, Vireos and their Allies, pp. 131–182. Dover Publications, Inc. New York; Chapman and Castro 1978. Wilson Bull. 84:496–497; Judd 1898. *In* Beal and Judd [eds], Cuckoos and Shrikes in their Relation to Agriculture, pp. 15–26. U.S. Dept. Agric., Div. Biol. Surv. Bull. 9; Miller 1932. Univ. California Publ. Zool. 50:531–643; Reid and Fulbright 1981. Southwest. Nat. 26:204–205; Scott and Morrison 1990. Proc. West. Found. Vert. Zoology 4:23–57; 1995. *ibid.* 6:186–193). Loggerhead Shrikes occasionally take prey of a mass that approaches their own (Balda 1965. Condor 67:359; Vaiden in Bent, *op. cit.*), but experiments have shown that where possible, they select smaller prey (Slack 1975. Auk 92:812–814). For the latter reason, we report here an attempt at predation by a Loggerhead Shrike on a relatively large prey, an adult *Sceloporus magister uniformis* from the Mojave Desert, California, USA.

On the relatively warm (air temperature ca.16°C max.), sunny, late afternoon of 26 December 1999, we noted a Loggerhead Shrike hovering above a large (ca. 2 m tall) *Yucca schidigera* along a rocky outcrop ca. 18 km NE Apple Valley, just W of Sidewinder Mountain, San Bernardino County (34°35'N, 117°03'W; elev. ca. 1000 m). As we approached, the shrike dropped into the base of the yucca and began to struggle to remove an object. Closer inspection revealed that the shrike was attempting to extract a large (> 100 mm SVL; ca. 40 g, Vitt et al. 1981. Ecology 62:398–410) male *Sceloporus magister*. When we approached to within 2 m, the shrike flew several meters away and perched on a Creosote Bush (*Larrea tridentata*) while the lizard retreated deep into the yucca. After we retreated several meters, the lizard reappeared within 5 min and the shrike renewed its attack. After struggling with the lizard for several more seconds, the shrike ceased its attack, flew off, and did not return during the ensuing 15 min we were at this site.

Hatchling and juvenile *S. magister* (largely < 20 g.; see Vitt et al., *op. cit.*) appear small enough to fall prey to loggerhead shrikes, but this species has not been reported in the diet of shrikes. Regardless, our observation suggests that adult *S. magister* are unlikely to routinely serve as prey for Loggerhead Shrikes.

We thank Brian Grogan for assistance in the field; Samuel Droege for researching food records of shrikes at Patuxent Wildlife Research Center; Laurie Vitt for literature; Marc Hayes for literature and helpful comments on the manuscript, and Christopher Briand for reviewing an early draft of the manuscript.

KRYSKO**, Florida Museum of Natural History, Division of Herpetology, P.O. Box 117800, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@flmnh.ufl.edu).

SCELOPORUS OCCIDENTALIS (Western Fence Lizard). **FAILED PREDATION BY SNAKE.** Despite the many adaptations of snakes for swallowing prey large relative to their body size (Cundall and Greene 2000. *In* K. Schwenk [Ed.], Feeding: Form, Function and Evolution on Tetrapod Vertebrates, pp. 293–333. Academic Press, San Diego, California), gape-size places an upper limit on the maximum size of prey that these animals consume (Shine 1991. Funct. Ecol. 5:493–502). However, gape-limitation may more strongly determine the size of prey successfully consumed than that attacked by snakes. Larger prey may still be attacked and even killed without being consumed if gape-limitation prevents ingestion after prey capture and dispatch. Here we report on an observation of failed predation by a snake on a gravid female *Sceloporus occidentalis* in which the egg mass carried by the female lizard prevented an otherwise successful predation event.

This observation took place in a riparian cobble bar habitat along the South Fork (SF) Eel River, Mendocino Co., California, USA. In coordination with an ongoing study of overnight retreat site selection by *S. occidentalis*, we had previously attached (8 June 1999) a 1.3 g radio transmitter (Holohil, Inc., Carp, Ontario,

Canada) to a gravid female lizard (70 mm SVL, 14.7 g). On the morning (0630 h) of 20 June 1999, we found this female dead and fully exposed on the cobble bar surface. This was the second largest *S. occidentalis* marked with a transmitter on the site. The head and thorax of this individual were severely compressed (Fig. 1) and coated with a shiny residue indicating that this animal had been partially swallowed. In addition, dried blood was found in the nostrils, suggesting that the lizard had been crushed in the process of being swallowed. The cylindrical compression of this animal extended posteriorly to ca. 15 mm from the pelvic region where the entire clutch (11 eggs, 3.7 g wet mass) was compressed against the posterior end of the abdomen. The radio transmitter was >15 mm posterior to the point of egg mass constriction.

These observations led us to conclude that this lizard had been captured, partially swallowed but regurgitated by a predator, most likely a gape-limited snake. Moreover, we conclude that the observed predation event was unsuccessful as a direct result of the girth of the gravid female. Snake predators of fence lizards, including Racers (*Coluber constrictor*) and juvenile Northern Pacific Rattlesnakes (*Crotalus oreganus*), are common at the SF Eel River. For example, on the evening prior to our discovery of the dead female lizard, we observed a Racer hunting a male Western Fence Lizard ca. 50 m from the point of discovery of the dead female. This snake continued to hunt after this first pursuit and may have attempted to consume the dead female lizard as well.

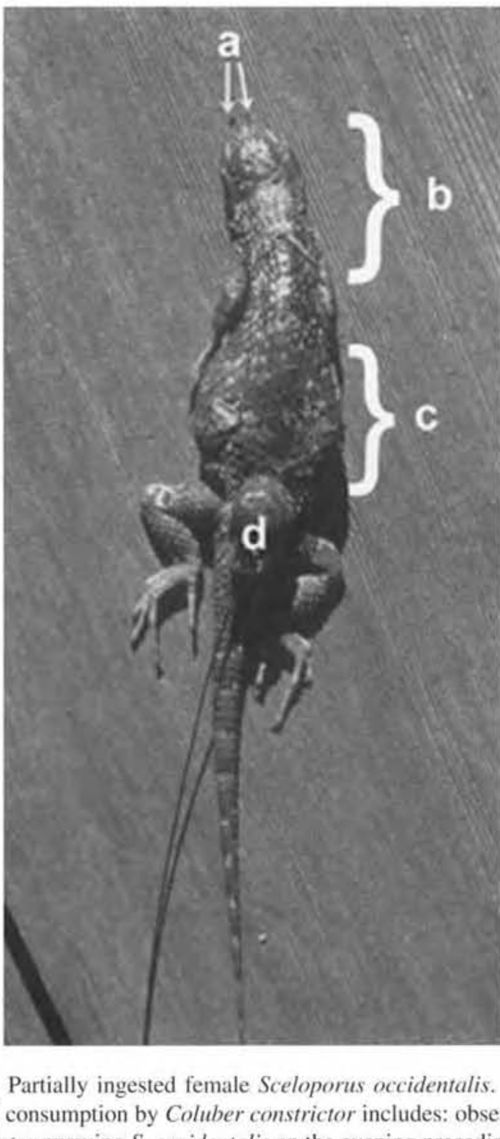

FIG. 1. Partially ingested female *Sceloporus occidentalis*. Evidence for partial consumption by *Coluber constrictor* includes: observation of *C. constrictor* pursuing *S. occidentalis* on the evening preceding the discovery of dead female, blood in nostrils (seen here as nostril accentuation, a), cylindrical anterior compression and glossy coat (b), clutch gathered in swollen posterior end of abdomen (c) but anterior to the radio transmitter (d).

The observation of failed predation is important because it demonstrates that the predation process in gape-limited snakes may involve successful and unsuccessful encounters, both of which may be unsuccessful from the perspective of the attacked prey. Predators may actively choose prey based on size-specific cues (e.g., prey body depth; Hambright 1991. Trans. Am. Fish. Soc. 120:500–508). Alternatively, prey size selection by predators may occur passively, as a result of diminished success in handling larger prey (Jaunes and Conover 1994. Mar. Ecol.-Prog. Ser. 114:59–69). In the latter case, attack may be independent of prey size but large prey may be more likely to escape an attack.

In the case of the observed gravid female lizard, failed predation may have occurred either because cues used by the snake to judge the size of non-gravid individuals (e.g., head width) did not apply to this large, gravid female lizard, or simply because successful handling, rather than attack, of prey was dependent on prey size. In either case, the lizard did not escape the attack as a result of a mistake made by its potential snake predator.

We thank D. DeNardo and K. Zamudio for advice on telemetry techniques with lizards. B. Butterfield, H. Greene, J. B. Hauge, J. Rodriguez, B. Suttle, and V. Vredenburg provided valuable comments on previous versions of this note. This study was funded by NSF grants grants DEB-FD 96-15175 to Mary E. Power et al., DEB-FD 97-00834 to JLS and MEP, and by the Department of Integrative Biology, UC Berkeley. JLS thanks the Museum of Vertebrate Zoology, UC Berkeley for supplying the radio receiver and the National Center for Ecological Analysis and Synthesis for support while completing this work.

SABO*** and **MARTIN KU**, Department of Integrative Biology, University of California, Berkeley, California 94720, USA.*Current address/corresponding author: Faculty of Ecology, Evolution and Environmental Science, School of Life Sciences, Arizona State University, USA; e-mail: John.L.Sabo@asu.edu.

SCELOPORUS UNDULATUS (Eastern Fence Lizard). **FIRE AVOIDANCE BEHAVIOR**. Few direct observations of reptile response to fire exist (reviewed in Russell et al. 1999. Wild. Soc. Bull. 27:374–384). Here, we report on the behavior of *Sceloporus undulatus* in response to a prescribed burn in northwestern Florida, USA.

At ca. 1130 h on 22 Mar 2003, we observed the behavior of two lizards for 10 min during a prescribed burn of a Longleaf Pine (*Pinus palustris*) – Turkey Oak (*Quercus laevis*) sand hill community at Eglin Air Force Base, Okaloosa County (30°31'N, 86°53'W; elev. 35 m). Prior to the arrival of the flames, lizards were basking on a dirt mound (ca. 0.5 m high) on the shoulder of a recently scraped road serving as a fire break. The low-intensity fire was moving less than 1 m per minute towards their location. As the fire approached, both lizards began digging separate bur-

rows into the side of the dirt mound and were completely buried by the time the flames were within 1 m of their locations. It is unknown what aspect of the fire (sight of the flames, heat, smoke, or sound of the fire) triggered their response. Unfortunately, our work required us to cease observation, and we were unable to determine the duration and effectiveness of the retreat.

TROPIDURUS HYGOMI (NCN). **CANNIBALISM.** Cannibalism, well known among lizards (e.g., Luiselli et al. 1999. J. Zool. 247:127–131), is described from continental (Kiefer and Sazima 2002. Herpetol. Rev. 33:136) and island (Stone and Snell 2002. Herpetol. Rev. 33:53) populations. In island populations, cannibalism is frequently interpreted as a response to scarcity of space and food resources, whereas in continental populations, it may be triggered by many factors, including group social structure. Here, we add to data on continental populations with an observation of cannibalism in *Tropidurus hygomi* from northeastern Brazil that may arise out of its group social structure.

In August 2002, during a field trip to the sand dunes of Salvador, Estado da Bahia (12°58'16"S, 38°30'39"W; elev. > 1 m), we observed a predatory episode involving an adult (62.3 mm SVL, 12.7 mm head width) male *T. hygomi* eating a conspecific juvenile male (26.5 mm SVL, 5.6 mm head width). The juvenile was in the shade of a small bush near the adult male. The latter quickly caught it by the neck without a chase, and then ate it head first. The adult took less than two minutes to swallow the juvenile. We collected the adult after it had eaten, and sacrificed it to examine its gut contents. Two hours after ingestion, the juvenile was almost intact, only its tail was broken. Both animals were deposited in the University of Bahia, Department of Zoology's museum collection, Salvador, Brazil (LVT collection numbers: adult: PEU-SQ-200201; juvenile: PEU-SQ-200202).

Lizards of the genus *Tropidurus* are territorial sit-and-wait predators (Bergallo and Rocha 1993. Amphibia-Reptilia 14:312–315) that are insectivorous, eating mostly ants (Rocha and Bergallo 1994. Herpetol. Rev. 25:69; Van Sluys 1993. J. Herpetol. 27:347–351). Cannibalism is known in *T. montanus* (Kiefer and Sazima 2002. Herpetol. Rev. 33:136), a saxicolous species from Estado de Minas Gerais, Brazil. Some *Tropidurus* found in rocky environments (e.g., *T. torquatus* and *T. itambere*) are socially organized as harems (TK, pers. obs.), with a dominant male, many females, juveniles, and other males living around the dominant male's territory. *Tropidurus hygomi* seems to exhibit a similar pattern of social organization. In such cases, coexistence of dominant males and juveniles may increase the likelihood of cannibalism.

We thank to Pedro L. B. Rocha for lab support at Federal University of Bahia, Salvador, Brazil. Funding provided by FAPESP (doctoral fellowship to TK - 00/06662-5), and authorization for collecting *Tropidurus* lizards was provided by IBAMA (022/02-RAN-IBAMA).

NAVAS**, Departamento de Fisiologia, Instituto de Biociências, Universidade de São Paulo, São Paulo, SP, Brazil.

TROPIDURUS HYGOMI (NCN). **JUVENILE PREDATION.** The diurnal, heliophilic, terrestrial lizard *Tropidurus hygomi* is a medium-sized (to 80 mm SVL) tropidurid endemic to "restinga" habitats (coastal xeric sand dunes) of northeastern Brazil. Despite its frequent occurrence at high densities, information regarding most aspects of its ecology or natural history is lacking. Only systematic studies and anecdotal observations exist (Vanzolini and Gomes 1979. Papéis Avulsos de Zoologia, São Paulo 21:243–259; Rodrigues 1987. Arquivos de Zoologia, São Paulo 31:105–230). Here, we report two cases of predation on juvenile *T. hygomi*.

On 13 February 2003, during a lizard community study of "restinga" habitat at Dunas do Abaeté (12°57'03"S, 38°22'30"W; elev. 15 m), municipality of Salvador, Estado da Bahia, one of us (EJRD) captured a juvenile *T. hygomi* (27.7 mm SVL) in a pitfall trap. After marking, the juvenile was released; as soon as it started moving away, it was attacked by an adult male *T. hygomi* (61.2 mm SVL) that emerged from nearby vegetation. The adult grabbed the juvenile by the mid-body region and swallowed it tail first. The capture and swallowing process took ca. 5 min. The adult was collected and deposited at the Museu Nacional, Rio de Janeiro (MNRJ 10036).

Occasional cannibalism is reported among other tropidurids, including *Liolaemus lutzae* also from Brazilian restinga habitat (Rocha 1992. Herpetol. Rev. 23:60), an insular *T. torquatus* in the Abrolhos Archipelago, Estado da Bahia (Dutra 1996. Bachelor's Thesis, Departamento de Biologia, Univ. Fed. de Minas Gerais. 48 p.), *T. torquatus* from Corrientes Province, Argentina (Alvarez et al. 1985. Historia Natural, Corrientes 31:281–288) and montane *T. montanus* (Kiefer and Sazima 2002. Herpetol. Rev. 33:136). Opportunistic foraging has been regarded as the main explanation for cannibalism in lizards (e.g., Polis and Myers 1985. J. Herpetol.19:99–107; Zamprogno and Teixeira 1998. Herpetol. Rev. 29:41–42) and might explain this pattern.

During a study of the feeding habits of the whiptail lizard *Cnemidophorus abaetensis* from the Dunas do Abaeté, one of us (EJRD), found a juvenile *T. hygomi* (35 mm SVL) in the stomach of an adult male *C. abaetensis* (65.2 mm SVL) on 4 October 1997. The whiptail is deposited at the Museu Nacional, Rio de Janeiro (MNRJ 8654). In a review of data available on cannibalism for lizard species from eastern Brazil, Rocha et al. (2000. *In* Esteves and Lacerda [eds.], Ecologia de Restingas e Lagoas Costeiras, pp. 117–149. NUPEM/UFRJ, Macaé, Brazil) showed that all cannibalistic events involved juvenile prey and adult predators. These authors suggested that cannibalism should be associated with species having sexual dimorphism in size and that the cannibalistic behavior should be more frequently displayed by individuals of the largest sex, usually males (in the only instance in which the female was the cannibal [the scincid *Mabuya frenata*],

females were the larger sex [Vrcibradic and Rocha 1996. Herpetol. Rev. 27: 201–202]). *Tropidurus hygomi* is sexually dimorphic in body size (Vanzolini and Gomes, *op. cit.*), with males being the largest sex, so our observations reinforce the idea of Rocha et al. 2000 (*op. cit.*). Our finding also indicates that *C. abaetensis* is a source of mortality for juvenile *T. hygomi* in the Abaeté restinga.

Davor Vrcibradic kindly reviewed the manuscript. We thank the Conselho Nacional do Desenvolvimento Científico e Tecnológico (CNPq, processes 300819-4 and 477981/03-8), the Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ) and Ideawild for funding.

ROCHA** (e-mail: cfdrocha@uerj.br), Setor de Ecologia, Instituto de Biologia Roberto Alcântara Gomes, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, 20550-019, Rio de Janeiro, RJ, Brazil.

TUPINAMBIS MERIANAE (Tegu). **DIET**. *Tupinambis merianae* is a generalist, but many aspects of its ecology remain unstudied. Even the most complete report on its diet does not specify the identity of most vertebrate species taken. This is especially true for amphibians despite the fact that anurans were recorded from 27% of tegus examined (Mercolli and Yanosky 1994. Herpetol. J. 4:15–19). At least one anuran has been identified from the related *T. teguixin* (Souza 2002. Herpetol. Rev. 33:209), but no anurans in *T. merianae* diet have been identified to species. For this reason, we describe an apparent predation event by *T. merianae* on a leptodactylid frog from southeastern Brazil.

On 16 January 1998 at ca. 1700 h, we encountered a small (ca. 40 cm shoulder height) "vira lata" dog with a dead juvenile male (17.4 cm SVL) *T. merianae* in its mouth at km 116 on road RS 030, Glorinha, Estate of Rio Grande do Sul (50°46'S, 29°52'W; elev. 58 m), in an abandoned horticultural plot in humid lowlands. Upon examination of the *T. merianae* removed from the dog's mouth, we found an adult *Leptodactylus ocellatus* (ca. 65 mm SVL) inside the lizard's mouth with its head in its throat.

During the predation event on this frog, the dog may have surprised the tegu. Because the frog was lodged in the throat of the lizard, it is unclear whether this represented a successful predation attempt by the lizard, or whether the dog took advantage of a lizard already encountering problems with an oversized prey item.

SERPENTES

CHILOMENISCUS STRAMINEUS (Variable Sandsnake). **PREDATION**. Although some scorpions occasionally prey on small vertebrates including snakes (Polis 1990. The Biology of Scorpions. Stanford University Press, Palo Alto, CA. 587 pp.), a search of the literature revealed no records involving *Chilomeniscus stramineus*. On 20 March 1997 at 1833 h MST in Maricopa County, Arizona, an adult female *Hadrurus arizonensis* (77 mm TL) was discovered under a cover board feeding on the anterior 35 mm of a *C. stramineus* (ASU 30878), which she clasped in her pedipalps. We estimate that the snake was ca. 180 mm TL, based on comparison with conspecific museum specimens.

Submitted by **PETER J. MAYNE**, 17510 N 85th Lane, Peoria, Arizona 85382, USA, and **RANDALL D. BABB**, Arizona Game and Fish Department Region VI Headquarters, 7200 E University Drive, Mesa, Arizona 85207, USA (e-mail: rbabb@gf.state.az.us).

CLONOPHIS KIRTLANDII (Kirtland's Snake). **REPRODUCTION**. Eight cover boards placed on a recently burned restored prairie near Allerton Park in Piatt County, Illinois yielded a male *Clonophis kirtlandii* (291 mm SVL, 13 g) on 14 May 2003. On 5 August 2003, a gravid female (415 mm TL, 38.0 g) was found under the same cover board. The female was fed earthworms of an unknown weight on 18 and 19 August 2003. A brood of 8 was born 23 August 2003. Mean length of the brood was 160 ± 77 mm TL (range = 151–171 mm). Mass averaged 1.3 ± 0.1 g (range = 1.421–1.209 g). Post-partum mass of the mother was 21.9 g, while the sum of the brood's mass was 10.7 g. Little is known of the natural history of *C. kirtlandii*, but feeding just prior to parturition appears to be unusual. Tucker (1976. J. Herpetol. 10:53–54) reported a 16-day interval between last acceptance of food and parturition and Conant (1943. Amer. Midl. Nat. 29:313–341) reported food was refused for two to three weeks prior to parturition. Brood size reported here approximates previously reported mean brood sizes of 7.8 (Conant, *op. cit.*) and 7.3 (Tucker, *op. cit.*). The most recent Piatt County record in the Illinois Department of Natural Resources Natural Heritage database is dated 1990.

CONOPHIS LINEATUS (Road Guarder). **REPRODUCTION.** *Conophis lineatus* is a colubrid that occurs from central Mexico to western Nicaragua (Savage 2002. The Amphibians and Reptiles of Costa Rica; A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago. 934 pp.). There are previous reports of clutches containing 4–6 eggs (Campbell 1998. Amphibians and Reptiles of Northern Guatemala, The Yucatán, and Belize. University of Oklahoma Press Norman, 380 pp; Savage, *op. cit.*). Here I report on a new maximum clutch record for this species.

One *C. lineatus* from Nicaragua (LACM 67653), 550 mm SVL, was collected January 1969 in León Department. It contained 8 oviductal eggs (mean length = 18.9 mm ± 1.1 SD, range = 17–21 mm), which is a maximum clutch size for *C. lineatus*. The eggs are deposited in the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

CROTALUS CERBERUS (Arizona Black Rattlesnake). **ENDOPARASITES.** The endoparasites of the Arizona Black Rattlesnake (*Crotalus cerberus*) have not been reported. Here we report on the presence of larvae (tetrathyridia) of tapeworms (Cestoda) and larvae (cystacanths) of spiny-headed worms (Acanthocephala) in this species.

The body cavities of 64 *C. cerberus* from Arizona from the herpetology collections of Arizona State University (ASU), Tempe, Arizona (N = 29) and the University of Arizona (UAZ), Tucson, Arizona (N = 35) were examined for helminths. A mid-ventral incision was made in the body wall, and organ surfaces and mesenteries in the posterior portion of the body cavity were visually examined. Oblong whitish bodies, ca 1 x 3 mm, were found in six snakes, which proved upon microscopic examination to be tetrathyridia (larvae) of *Mesocestoides* sp. (ASU 7038, UAZ 27860, 27862, 27924–925) or oligacanthorhynchid acanthocephalan cystacanths (UAZ 27922, 27860, 27925). Prevalence of infection (percent of infected snakes in sample) and mean intensity ± SD (mean number parasites per infected snake) and range for *Mesocestoides* sp. was 8%, 9.6 ± 8.2, 1–23; oligacanthorhynchid acanthocephalan cystacanths, 5%, 1. Voucher specimens were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as tetrathyridia of *Mesocestoides* sp. (USNPC 94151) and acanthocephalan cystacanths (USNPC 94152).

Mesocestoides sp. and oligacanthorhynchid cystacanths are commonly found in North American rattlesnakes. Their occurrences were summarized in Goldberg and Bursey (2000. Herpetol. Rev. 31:104). Both have since been found in *Crotalus enyo* (Goldberg et al. 2003. Herpetol. Rev. 34:64–65 and oligacanthorhynchid cystacanths in *Crotalus cerastes* (Goldberg and Bursey 2002. Herpetol. Rev. 33:138). Rattlesnakes may serve as paratenic (transport) hosts for species of *Mesocestoides* (Bolette 1997a. J. Parasitol. 83:751–752) and acanthocephalans (Bolette 1997b. Southwest. Nat. 42:232–236). *Crotalus cerberus* is a new host record for both tetrathyridia of *Mesocestoides* sp. and cystacanths of oligacanthorhynchid acanthocephalans.

We thank M. E. Douglas (formerly of Arizona State University) and G. L. Bradley (University of Arizona) for permission to examine snakes in their museums.

BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA; (e-mail: cxb13@psu.edu).

CROTALUS MOLOSSUS (Black-tailed Rattlesnake). **FATAL INGESTION**. At 2128 h on 25 July 2003 we collected a dead male *Crotalus molossus* (UTEP 18857, 760 mm SVL, 313.3 g including stomach contents) on the shoulder of State Route 96 in Yavapai Co., Arizona, 26.7 road miles E of the junction with State Route 97 (34°28.023'N, 112°48.178'W, 1190.5 m elev.). Upon dissection, an exceptionally large mid-body bulge yielded a 125.3 g White-throated Woodrat, *Neotoma albigula* (identification by A. H. Harris). Comprehensive examination revealed no signs of externally inflicted blunt trauma. The skin was free of abrasive injuries and free of subcutaneous bleeding. Apart from obvious mid-body distortion, the internal organs, viscera, and major vessels were intact. We also failed to note any fractures in a skeletal preparation of the specimen. In view of the evidence presented we consider death due to injury by automobile or predator unlikely. Ingestion of prey often compromises locomotory performance in snakes, particularly endurance capacities (Garland and Arnold 1983. Copeia 1983:1092–1096). In this case a prey/predator mass ratio of 0.67 may have severely compromised locomotory ability and, along with some other circumstance, resulted in exposure to lethal daytime temperatures. Alternatively, the prey bolus may have constricted vital anatomical structures.

Although the ability to capture and ingest large prey items has obvious adaptive benefits for snakes, large prey/predator size-ratios can also increase vulnerability to predation and exposure to lethal temperatures (Fitch 1949. Amer. Midl. Nat. 41:513–579; Holycross et al. 2001. Southwest. Nat. 46:363–364; Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. University of California Press, Berkeley. 1533 pp.; Mulcahy et al. 2003. Herpetol. Rev. 34:64; Pauly and Benard 2002. Herpetol. Rev. 33:56–57; Turner 2001. Herpetofauna 31:112–115). Whereas some of the extreme prey/predator weight-ratios are captivating and compelling, less drastic ratios might also result in death. Unfortunately, there has been no attempt to quantify the relationship between variation in prey/predator mass ratios and mortality, let alone locomotory performance.

Submitted by **RANDY L. POWELL**, Natural Toxins Research Center, MSC 158, Texas A&M University at Kingsville, Kingsville, Texas 78363-8202, USA (e-mail: randy.powell@tamuk.edu); **MATTHEW McMILLAN**, University of Nevada at Reno, Biological Resources Research Center, Las Vegas Field Station, 2331 Silverwolf Drive, Henderson, Nevada 89015, USA; and **JENNIFER D. FARANCIA ABACURA (Mud Snake). **COURTSHIP BEHAVIOR.** Courtship behavior by *Farancia abacura* is undescribed (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington and London. 680 pp.). Although Meade (1937. Copeia 1:12–15) reported mating, it apparently was not preceded by courtship behavior.

Here we report courtship behavior in *F. abacura* for the first time, on a trail separating a tupelo-gum swamp from annually flooded hardwood bottomlands on Mound Island in the Mobile-Tensaw Delta Wildlife Management Area (Baldwin Co., Alabama, USA). On 19 June 2003 at 1430 h we spotted the movement of the dorsum of what appeared to be a single *F. abacura* at the surface of a pool of rainwater (15 m x 3 m). The snake appeared to be struggling with something underwater. Upon capture with tongs, it became clear that there were two *F. abacura*, intertwined in a loose ball. The male (ca. 1000 mm TL) was biting the female's (ca. 1200 mm TL) neck and attempting cloacal apposition. Hemipenes were not observed, suggesting that intromission had not yet occurred (Seigel et al. 1987. Snakes: Ecology and Evolutionary Biology. McGraw-Hill Inc., 529 pp). Despite handling, the pair appeared oblivious to our presence and continued court-

ship behaviors. The male was forcibly removed from the female's neck three minutes after capture by applying light pressure to the anterior portion of his jaws. Minuscule teeth marks were observed on the female's neck. Although the snakes were released together in the pool, no further courtship behavior was observed. It was partly cloudy with no breeze, the air temperature was 32°C, and water temperature was ca. 25–27°C.

We thank D. H. Nelson, B. Gill, T. Rice, and the Alabama Department of Conservation and Natural Resources.

HIEROPHIS VIRIDIFLAVUS (European Whip Snake). **COLOR CHANGE**. In heterotherm animals, color change can be physiological or morphological. The former is caused by displacement of melanosomes along the processes of dermal melanophores and occurs over minutes or hours, the latter is due to the change in the number of melanosomes and/or melanophores and occurs over weeks or months; for example during ontogenesis or between different seasons of activity (e.g., Johnston 1994. J. Herpetol. 28:109–112 and citations therein). Morphological changes in color and/or reflectance are seldom reported in snakes, but have been reported in four elapids (Banks 1981. Herpetofauna 13:29–30; Johnston, *op. cit.*; Johnston 1996. J. Zool. 239:187–196; Mirtschin 1982. Herpetofauna 14:97–99) and in one viperid (Rehák 1987. Vest. s. Spole. Zool. 51:300–303; Madsen and Shine 1992. Evolution 47:321–325). To our knowledge, only physiological color changes have been observed in colubrids (natural: Boundy 1994. Herpetol. Rev. 25:126–127, in *Thamnophis rufipunctatus*; induced: Rahn 1941. Biol. Bull. 80:228–237, in five American species).

Two adult *Hierophis viridiflavus* changed their body color during the course of radio-telemetric observations in Groane Natural Park in Lombardy, Italy. In this region, color pattern varies from black-and-yellow patterned dorsum with a pale yellow venter to melanotic (i.e., no yellow markings, with a pale grey or cream belly). During the study, we captured 34 adult snakes and recaptured three. Snakes were individually marked by scale clipping, sexed, measured, and color and pattern were also recorded (usually photographically). A very dark male (940 mm SVL, 1250 mm TL) captured on 4 June 1999 was radio-tagged and released. It was recaptured 21 June 1999 with a head wound, due to a dog bite. Over the course of a month-long recovery in captivity, this snake shed several times. With each shedding episode, the yellow coloration typical of the species became increasingly evident, ultimately attaining typical dorsal coloration and pattern. A female (900 mm SVL, 1160 mm TL) captured and radio-tagged 16 of September 1998 showed a bright black and yellow coloration but when recaptured on 21 October 1998 appeared melanotic. In both cases, the color change appears to be morphological (Johnston 1994, *op. cit.*).

LAMPROPELTIS GETULA CALIFORNIAE (California Kingsnake). **OVIPOSITION SITE**. Records of reproduction in northern populations of *Lampropeltis getula* are rare (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow. 332 pp.; St. John 2003. Reptiles of the Northwest: Alaska to California; Rockies to the Coast. Lone Pine Publ., Edmonton, Alberta, Canada. 272 pp.), as they are for most snakes at the northern edge of their distribution (Blem 1981. Brimleyana 5:117–128). At 1800 h on 20 September 2003 near Roseburg, Oregon I found the recently shed skins of nine hatchling *L. getula* surrounding a burrow (within 1 m). A tenth sloughed skin was found in a burrow 4.2 m away. Excavation revealed that the burrows descended vertically and were joined at a depth of ca. 19 cm by a straight tunnel. A recently shed hatchling male *L. getula* (ca. 220 mm SVL) was found basking ca. 1 m from the first burrow. The burrows, skins, and hatchling were below an electric fence separating a gravel driveway from a grass field and ca. 23 m from a small, artificial wetland established 6 years earlier via damming of an intermittent stream. *Lampropeltis getula* shed within 9–13 days of hatching and disperse almost immediately thereafter (Tu et al. 2002. J. Exp. Biol. 205:3019–3030). For this reason I believe the eggs were oviposited and hatched inside the burrow. Although within 20 km of the northern limit of the species' range, this record coincides with most aspects of kingsnake reproduction in other regions. Specifically, oviposition of 2–12 eggs in rodent burrows near wetlands is not atypical (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C., 680 pp.).

MASTICOPHIS FLAGELLUM RUDDOCKI (San Joaquin Coachwhip). **CANNIBALISM**. Cannibalism or attempted cannibalism by *Masticophis flagellum* has been reported once in captivity (Cunningham 1959. Herpetologica 15:17–19) and three times in the wild (Guidry 1953. Herpetologica 9:49–56; LaDuc and LaDuc 2003. Herpetol. Rev. 34:252). Watson and Stuart (2003. Bull. Chicago Herpetol. Soc. 38:222) report cannibalistic carrion feeding in *M. flagellum* and suggest cannibalism "does not appear to be common in this species." I found a *M. flagellum ruddocki* (ca. 1.2 m TL) swallowing a slightly smaller conspecific headfirst at ca. 1100 h on 22 April 2001 on the Carrizo Plain National Monument (35°02'45.8"N, 119°36'18.2"W; 696 m elev.), San Luis Obispo County, California, USA. Forty minutes later, neither snake was observed during a brief search of the site. This observation is novel for the subspecies and suggests cannibalism is not uncommon in *M. flagellum*.

NATRIX NATRIX (European Grass Snake) **MALE COMBAT**. On 1 May 2001 during my field studies in the Stawy Milickie Nature Reserve (51°31'51"N, 17°20'12"E; Wroclaw, Poland) I observed two male (545 and 555 mm SVL) *Natrix natrix* engaged in combat in the presence of a female. Each male attempted to force his rival's anterior body to the ground. The snakes were often completely entwined. After three to five minutes the female moved into high grass, apparently in response to my presence, while the males continued to fight. After half a minute the males rapidly moved 60–70 cm forward, while still wrestling. This sequence was repeated several times before the two males suddenly ceased combat (ca. four minutes after the female left) and both began to follow the female's path while rapidly flicking their tongues. At this point I captured both males and measured and marked them for future identification.

Although *N. natrix* is common across most of Europe, this is the first report of combat in the species. The only previously reported form of male-male competition is tail wrestling (e.g., Madsen 1983. Oikos 40:77–82). Male combat can shape population structure and lead to the evolution of sexual size dimorphism (Shine 1993. *In* Seigel and Collins [eds.], Snakes: Ecology and Behavior, pp. 49–86. McGraw Hill, New York; Shine 1994. Copeia 1994:326–246) and is given much attention in snake studies. It is therefore difficult to conceive how such a conspicuous behavior has remained unreported in this common and widespread species. I believe that male combat is not ubiquitous in *N. natrix*, and expression of the behavior might vary geographically.

AMBYSTOMA TALPOIDEUM (Mole Salamander) USA: ARKANSAS: Clark Co: Populations of *Ambystoma talpoideum* in southwestern Arkansas appear to be isolated or disjunct from populations in northern Louisiana, northeastern Texas, and eastern Oklahoma (Trauth et al. 1993. Proc. Arkansas Acad. Sci. 47:154–156; Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 509 pp; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C., 587 pp; Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville, 421 pp.), and available information seldom defines whether populations are metamorphic or paedomorphic. Recent records (Caldwell and Tumlison 2003. Herpetol. Rev. 34:379; Tumlison and Campbell 2002. Herpetol. Rev. 33:143–144) prompted a survey for *A. talpoideum* in southwestern Arkansas, outside of its previously known range. Using dipnets and seines, we sampled aquatic habitats because aquatic *A. talpoideum* are more easily captured than the burrowing terrestrial adults (Bishop 1947. Handbook of Salamanders. Comstock Publishing Company, Inc, Ithaca, New York). All specimens are housed in the Henderson State University (HSU) Vertebrate Collections in Arkadelphia, Arkansas. Identifications were verified by Stan Trauth. Metamorphic salamanders were collected from temporary pools. Paedomorphic forms were collected in small, permanent, fishless ponds. Clark Co., 0.8 km NW Gurdon (S27 T9S R21W), 23 February 2002 and 15 March 2002, R. Tumlison, HSU 903–906 paedomorphic larvae, HSU1281 metamorphic form. Other paedomorphic and metamorphic specimens from Clark County locations are catalogued as HSU 1041, 1278, and 1299. Columbia Co., 3 km E McNeil (S16 T16S R20W), 25 April 1992, R. Tumlison, HSU1282, metamorphic larvae. Dallas Co., jct. County Roads 245 and 247 (S6 T9S R17W), 22 April 2003, B. Caldwell and T. Fulmer, HSU 1293, metamorphic larvae. An additional Dallas County specimen is catalogued as HSU 1294. Hempstead Co., County Rd. 32, 0.6 km from jct. with County Rd. 27 (S9 T9S R26W), 26 April 2003, B. Caldwell, HSU 1295, metamorphic larvae. Howard Co., 5 km W jct. Hwys 26 and 369, (S30 T8S R27W), 27 and 28 April 2003, B. Caldwell, HSU 1297, 1302, metamorphic larvae. Pike Co., 3 km SW of Murfreesboro, off Hwy 27 (S14 T8S R26W), 27 April 2002 and 26 April 2003, B. Caldwell and T. Fulmer, HSU 1274, 1300, metamorphic larvae. Additional Pike county vouchers are catalogued as HSU 1275–1277, 1279, 1296, and 1305.

We thank Stan Trauth for verifying identification of specimens, Fred Kizzia for permission to collect on his land, and Tobin Fulmer for field assistance.

Photographic Identification as a Noninvasive Marking Technique for Lacertid Lizards

ANNA PERERA*
and
VALENTÍN PÉREZ-MELLADO
Department of Animal Biology, University of Salamanca
Campus Unamuno, s/n, 37071 Salamanca, Spain
**e-mail: a21279@usal.es*

Color and body patterns have long been used to identify individual lacertid lizards (Schmidt-Loske 1996), but may be unsuitable for long-term studies because they vary with reproductive condition, age, and other factors (Henle et al. 1997). Elbing and Rykena (1996) found that individual *Lacerta viridis* could be recognized by patterns of head scalation, and although these scales do not vary over time (Fox 1975), Elbing and Rykena (1996) considered this method of identifying individuals to be excessively time consuming and, in some cases, difficult to use because of the small size of the scales. Recently, Steinicke et al. (2000) found photographic identification of the scales of the first four rows of ventrals to be a suitable technique for recognizing individuals of five species of lacertids (*Lacerta agilis*, *L. bilineata*, *L. viridis*, *L. vivipara*, and *Podarcis muralis*). Photographic identification of individuals by means of scale patterns is an emergent technique with a promising future, but it is necessary to examine other species before it can be considered suitable for lacertids, and other lizards generally. The method also must be improved to reduce the time required for identification, especially when many individuals are involved in the study.

We tested the suitability of using ventral scalation to identify individual *Lacerta perspicillata* (SVL = 46.8 ± 0.34, range: 40.5–54.0, N = 99; unpubl. data). From November 2000 to May 2001, we collected 53 individuals on Menorca Island, Spain. We toe clipped and took two pictures of each lizard with a digital camera (Sony Mavica®). Digital photographs (resolution 640 x 480 pixels) were enhanced in the laboratory with Microsoft Photo Editor® (brightness, contrast, and conversion from color to black and white) and printed (600 x 300 dpi). Ninety-three recaptures of the 53 toe-clipped lizards were identified from photographs using ventral characters (i.e., scales of the chin and collar area, arrangement of scales in the chest area and of the longitudinal and transverse scale rows of the trunk, Fig. 1) by two observers. Photographic identification of individuals matched identification based on toe clips in 100% of cases. All individuals were easily identified, and no apparent change in scale pattern was noted.

Our method was subsequently used in a capture-recapture study involving the same population later the same year (June–October 2001). Lizards were photographed and individuals were added to a previously assembled reference collection of pictures. Individuals collected in the field were identified via comparison with the reference file. To reduce time spent on identification, the photographic reference file was organized by sex, and then by natural amputations, scale anomalies (e.g., aberrations, asymmetries), and

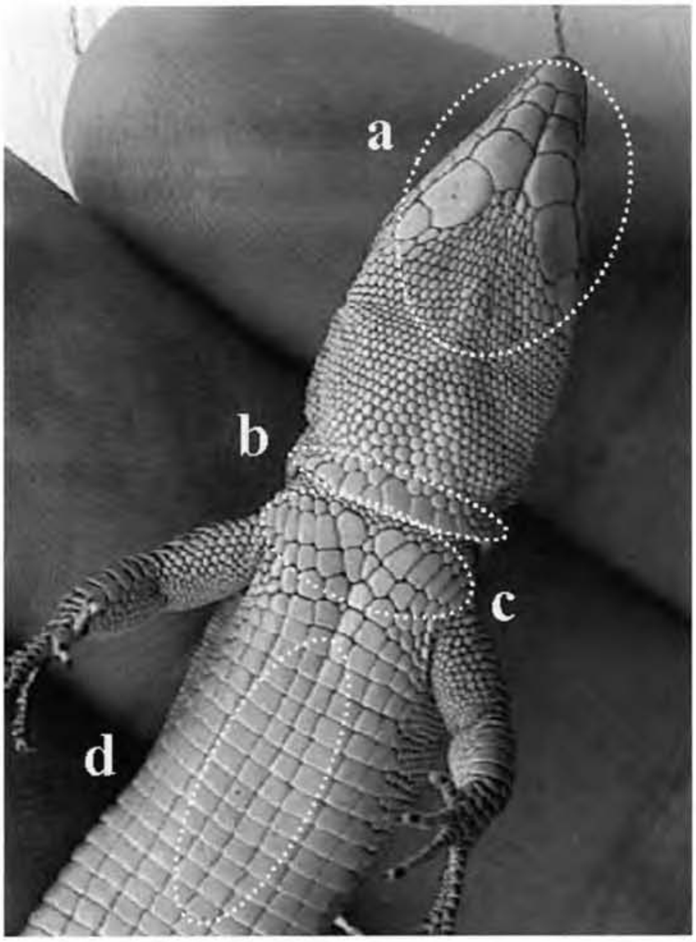

FIG. 1. Ventral characters used in the reference file: (a) chin-scale symmetry, (b) collar scales, (c) scale arrangement in chest area, and (d) position of longitudinal and transverse rows.

the ventral scale characters illustrated in Fig. 1. Consequently, the time needed to identify a lizard was reduced to < 2 min.

Our study corroborates the findings of Elbing and Rikena (1996) and Steinicke et al. (2000) and extends the use of photographic identification of lacertid scalation patterns as a means of permanent specimen identification in field studies. Digital cameras and printers greatly reduce the time and expense required for this technique, making individual recognition by means of photographic identification only slightly more time consuming and expensive than toe clipping. However, photographic identification has the advantage of being both nontraumatic and permanent, making it suitable for field research.

Acknowledgments.—We thank G. Cortázar and R. Jovani for help in the field, and "Lithica" for facilities utilized during the study. Special thanks are due to R. Jovani, R. Brown, R. Espinoza, and an anonymous reviewer for suggestions that greatly improved the manuscript. Financial support was provided by project PB98-0270 and an FPI grant by the Spanish Ministry of Science and Technology to A. Perera. This research was conducted under permit from the Balear Government (8001/2001).

A Preliminary Test and Report on the Efficiency of a New Funnel Trap for Semi-Aquatic Snakes

JEAN-JAY MAO

and

GERRUT NORVAL
Global Village Education Center. No. 436, Chong-San Rd. Chiayi City 600
Taiwan, R.O.C.

Baited and unbaited glue-traps (Glor et al. 2000; Vargas 2000; Whiting 1998), funnel traps with and without floats (Casazza et al. 2000), drift fences in conjunction with pitfalls, round and square funnel traps (Christiansen and Vandewalle 2000), and habitat traps (Allan et al. 2000) have recently been proposed for the collection of reptiles and amphibians. Several collection techniques, such as collecting by hand, drum nets, fykenets, and funnel traps, have been successfully used for ecological and life history studies of aquatic or semi-aquatic snakes (Casazza et al. 2000; Fitch 1986; Shine 1986). In long-term ecological studies, funnel traps have proven to be an efficient method to systematically collect specimens, not only for aquatic species, but also for terrestrial and arboreal species (Casazza et al. 2000).

From August to October 2002, we conducted a preliminary population study on three sympatric water snakes (*Enhydris chinensis*, *Enhydris plumbea*, and *Xenochrophis piscator*) in Tamsui, Taipei County, Taiwan. Over a period of three months, two funnel trap-types were utilized in this population study to determine their effectiveness. During the three-month test, a total of 20 medium-size shrimp funnel traps (12.5 cm diameter) and 15 small-size (10 cm diameter) funnel traps modified with polyvinyl chloride (PVC) piping (referred to in the text as PVC funnel traps) were set in a private farmland composed of five ponds and adjacent paddy fields. The medium-size (12.5 cm diameter) shrimp funnel trap was 35 cm in length with a single entrance. The first funnel is situated in the entrance of the trap and the second funnel is positioned ca. 11 cm into the trap, with the funnel cones pointing inwards. A container compartment is created by the remaining part of the trap (Fig. 1). These traps were positioned horizontally and half-submerged along the shoreline of the pond and paddy field habitat

with pegs at approximately three-meter intervals.

The new PVC funnel trap is an inverted "T" in design (Fig. 1) and it has two entrances, one at each side of the bottom, with an upright vertical air circulation pipe to prevent the snakes from drowning once they become trapped. Every PVC funnel trap was constructed out of the container compartment and two entrance parts of the small-size shrimp funnel traps (10 cm in diameter). These parts were attached to a 50 cm long PVC pipe (80 mm inside diameter) fitted to a PVC T-piece connector as follows: the PVC pipe was attached to the T-piece connector, the container compartment was fitted to the upright end of the PVC pipe and the two entrance parts, fitted with funnels, were attached to the two open ends of the T-piece. Every PVC trap was kept in an upright position by tying it to a bamboo rod planted in the mud of the pond bottom. The PVC trap can also be tied to the vegetation. When the trap is set in a deep-water trapping site the air circulation pipe can be extended by attaching another pre-manufactured PVC connector. Some semi-aquatic snake studies have indicated that individuals of different gender and size utilize different water depths (Shine 1986). For that reason, every PVC trap is calibrated on the vertical air circulation pipe for measurement of water depth (Fig. 1). The PVC traps were set at approximate equal intervals from each other in the testing pond habitat. Both trap-types were baited with loaches (*Misgurnus anguillicaudatus*) to increase the capture rate.

After three months and 1636 trap-nights, we collected a total of 49 snakes of four species (Table 1) using both trap-types. Snakes were marked and released, and some snakes were trapped more than once, resulting in a total of 70 snake captures. The trap-rate was 3.42 per 100 trap-nights in the PVC traps (33 snakes in 965 trap-nights) and 5.51 per 100 trap-nights in the medium-size shrimp funnel trap (37 snakes in 671 trap-nights). Because of the water depth of the test ponds, the water depth of the PVC funnel traps was between 21 and 97 cm, much deeper than the unmodified shrimp funnel traps (< 12 cm). At this depth *E. chinensis* was more effectively trapped with the PVC funnel traps than *E. plumbea* and *X. piscator*, which might reflect some difference in microhabitat utilization among these species.

The unmodified medium-size shrimp funnel traps were effectively utilized in shallow aquatic conditions (e.g., creeks, ditches, rice paddies, and swamp habitats) in population studies of the two species of *Sinonatrix* snakes in Taiwan by the first author (Mao 2003) and in the present test. Various amphibian and reptile species and individuals of the same species, but in different age classes, might utilize different aquatic environments and depths. In deep pond environments, the PVC funnel trap proposed here allows trapping at greater depths than standard funnel traps and offers great potential for semi-aquatic snake studies.

TABLE 1. Comparison of trap rates (per 100 trap-nights) of unmodified shrimp funnel traps and PVC funnel traps. The PVC traps were used in a pond, and the shrimp funnels in swamp, creek, ditch and paddy field. *Sinonatrix* data from Mao (2003).

Species	PVC funnel trap-rate/100 nights (965 nights)	Shrimp funnel trap-rate/100 Nights (671 nights)
Enhydris chinensis (N = 32)	2.8	0.75
E. plumbea (N = 2)	0.0	0.30
Xenochrophis piscator (N = 35)	0.62	4.32
Bungarus m. multicincintus (N = 1)	0.0	0.15
Sinonatrix spp. (N = 617)	—	2.75

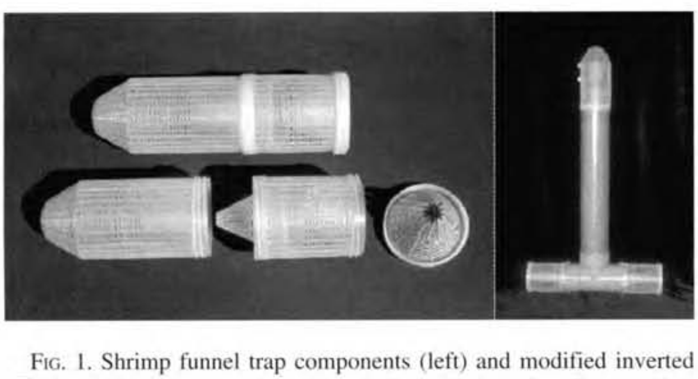

FIG. 1. Shrimp funnel trap components (left) and modified inverted "T" design (right). The upright vertical air circulation pipe allows snakes access to air.

Rates of Tricaine Methanesulfonate (MS-222) Anesthetization in Relation to pH and Concentration in Five Terrestrial Salamanders

JASON LOWE
2566 Menlo Avenue
Clovis, California 93612, USA
e-mail: jason.lowe@mindspring.com

Tricaine methanesulfonate (MS-222) is commonly used to anesthetize fish and amphibians, but while studies have investigated its effects on fish, no studies have been carried out on terrestrial salamanders (e.g., family Plethodontidae). Existing general guidance recommends MS-222 baths of 500 mg/L for anesthetizing adult salamanders (Cooper 2003), however species-specific dose recommendations and pH buffering instructions are nonexistent. Neutralizing the pH of MS-222 solutions is necessary because when dissolved in water with poor buffering ability, such as tap or distilled water, MS-222 lowers the pH (Smit et al. 1977). For example, a 50 mg/L MS-222 solution prepared using distilled water has a spontaneous pH of 3.9, and a 5000 mg/L solution has a spontaneous pH of 2.8 (Ohr 1975a). Such low pH baths induce anesthetization more slowly than neutral solutions (Smit and Hattingh 1979; Ohr 1975a), and low pH solutions injure the epithelial transport systems for sodium chloride and water in leopard frogs (*Rana pipiens*; Ohr 1975b). Crawshaw (1993) recommends neutralizing the pH by adding sodium bicarbonate, but this method is cumbersome because the reaction takes some time to equilibrate, which can cause difficulty in determining the appropriate amounts of sodium bicarbonate required to attain neutrality. For example, adding 3.5 g of sodium bicarbonate to 250 ml of a 2000 mg/L MS-222 solution results in a spontaneous pH of 7.0, however after 4 hours the pH will reach >8.2 (pers. ob.).

I experimented with commercially available aqueous pH buffers consisting of dihydrogen potassium phosphate and sodium hydroxide (Fisher Scientific, catalogue numbers SB112-20, SB108-10, SB104-20) to stabilize the pH of MS-222 (Sigma, catalogue number A-5040) solutions. I investigated the relation of pH and concentration on anesthetization time in five terrestrial salamander species (*Plethodon elongatus, P. cinereus, Ensatina eschscholtzii, Batrachoseps attenuatus, Desmognathus ocoee*). I tested the null-hypotheses that there are no differences in anesthetization time among three pH levels (6, 7, 8), between two concentrations (2000 mg/L, 500 mg/L), or among species.

Materials and Methods.—Twenty salamanders (4 each of the five species) were subjected to six experimental treatments of MS-222 that included two concentrations (2000 mg/L and 500 mg/L) at three pH levels (6, 7, 8). Salamanders were submerged in the aqueous solutions and timed with a stopwatch until they were completely anesthetized. The criterion for complete anesthetization was the inability to right themselves when turned onto their backs. The experiment was stopped if after 30 minutes a salamander was not completely anesthetized. Full submersion of terrestrial salamanders may have caused stress to the animal as vigorous swimming behavior was observed for the first few seconds of anesthetizing. As an alternative method, salamanders could be partially submerged in a more shallow bath that would allow their heads to remain out of the anesthetizing solution. Following anesthetization, salamanders were rinsed with water and aquarium conditioner and allowed to recover. Salamanders were housed in an environmental control chamber at 14°C in plastic containers with clay pot shards and moist paper towels prior to and between experiments. Salamanders were fed fruit flies once per week. Aqueous solutions of MS-222 were at room temperature, and salamanders were acclimated to room temperature for 30 minutes prior to anesthetization. MS-222 solutions were prepared by mixing MS-222 powder with aqueous pH buffers. For a 2000 mg/L concentration, 0.5 g MS-222 was mixed with 250 ml of aqueous buffer. For a 500 mg/L concentration, 0.125 g MS-222 was mixed with 250 ml of aqueous buffer.

I used a three-factor repeated measures experimental design with time to anesthetization as the response variable and factors being species, pH, and concentration. Six repeated measures, representing the six treatment combinations of pH and concentration, were taken on each subject. The washout period (time between treatments) in repeated measures designs is intended to be long enough to allow subjects to fully recover, thereby preventing a previous treatment from affecting the outcome of a following treatment. I observed that after anesthetization with a 2000 mg/L solution of MS-222 at pH 7, salamanders were able to lift their heads and walk within 17 (± 2 SE) minutes. Hormonal effects of acidic (pH 3) MS-222 baths endure at least 5 h after anesthetization of leopard frogs, but these effects were attributed to the acidity of the baths not MS-222 itself (Ohr 1975b). Arterial pH of bullfrogs (*Rana catesbeiana*) exposed to neutralized (pH 7.4) and acidic (pH 3) MS-222 baths return to normal levels after one day (Ohr 1975b). No information exists on long-term physiological recovery or the effect of repeated anesthetizations. Therefore, I chose a washout period of 14 days between treatments. Repeated measures ANOVA requires the assumption of circularity, which is met when treatment effects are independent. When the assumption of circularity is not met, I report Box's epsilon adjusted p-values. A sample size of 4 individuals each of the five species (20 salamanders total) was chosen because only that number was available in the lab. I used the computer program Number Cruncher Statistical Systems™ 2000 (J. Hintz, Kaysville, Utah) to perform two, 2-factor repeated measures ANOVA tests. Factors were species and pH in one test and species and concentration in the other. I used Tukey-Kramer's multiple comparison procedure to differentiate groups of species according to their anesthetization time. The response variable (time in seconds) was normalized by the log transformation. I analyzed the effect of snout-vent length (SVL), weight, and SVL-weight ratio as potential covariates using Pearson's correlation coefficient.

Results.—The time required for treatment solutions of MS-222 to anesthetize salamanders ranged from 1 minute 9 seconds to 30 minutes (mean = 7 minutes 5 seconds) and varied by species, pH, and concentration (Fig. 1). Snout–vent length, weight, and SVL-weight ratio were not significant covariates to anesthetization time ($R = 0.14, 0.01, 0.13$ respectively). Significant differences were found in the ANOVAs among species, among pH levels, and between concentrations (Table 1).

Tukey-Kramer's multiple comparison procedures, which were applied to each ANOVA test separately, produced the same species grouping pattern in the pH ANOVA as in the concentration ANOVA. In both tests the two members of the genus *Plethodon*

took significantly longer to anesthetize than the other species (concentration ANOVA: MSE = 0.02, CV = 4.37; pH ANOVA: MSE = 0.03, CV = 4.37). Tukey-Kramer's multiple comparison procedures used on the pH factor showed that the significant differences among pH were between pH 8, which took less time to anesthetize, and pH 6 and 7, which took more time (MSE = 0.01, CV = 3.51). Significant interaction terms in both ANOVAs (Table 1) indicate that the manner in which species were affected by treatments of a factor were not consistent between treatments of that factor.

TABLE 1. Species, pH, and concentration had significant effects on time to anesthetization (repeated measures ANOVA), but interaction terms were also significant indicating that the degree of change between levels of a factor was not consistent among species. Tukey-Kramer's multiple comparison procedures showed pH 6 and 7 were different than pH 8 (MSE=0.01, CV=3.51) and *Plethodon* species were different than all others (MSE=0.02, CV=4.37).

Response Variable	Source of Variation	DF	MS	F	p
Time (seconds)	A: species	4	0.42	12.37	0.0001
	B(A): individual	15	0.03		
	C: pH	2	0.41	28.76	<0.0001*
	AC	8	0.03	4.63	0.0016*
	BC(A)	26	0.01

	BC(A)	15	0.02		

* Box's epsilon adjusted p-value.

Discussion.—Using aqueous pH buffers to prepare MS-222 solutions is a convenient way to keep the solution pH stable. Because neutralizing pH using sodium bicarbonate results in solutions that require up to an hour or more to equilibrate, it is difficult to judge the amount of sodium bicarbonate needed without laboratory tests. Using an aqueous pH buffer simplifies the pH buffering procedure. These results show that using a pH 8 buffer will have a significantly different effect (less time to anesthetization) than using either a pH 6 or 7 buffer. The question of whether to use a pH 7 or pH 8 buffer remains open. Ohr (1975a) recommended adjusting the pH to between 7 and 8 to prevent injury to the skin and prevent stress, and she noted that leopard frogs appeared calm in MS-222 baths at pH 7.4 (Ohr 1975b) and *Necturus* appeared calm when placed in MS-222 solutions at pH 7.7 (Ohr 1975a). My experiment did not quantify levels of stress, and no information exists on amphibian stress responses in solutions of pH 8 or higher. Because MS-222 baths at pH 7 induce anesthetization in a reasonable amount of time and the faster anesthetization times at pH 8 are associated with an unknown level of stress, I recommend using a pH 7 buffer unless species-specific

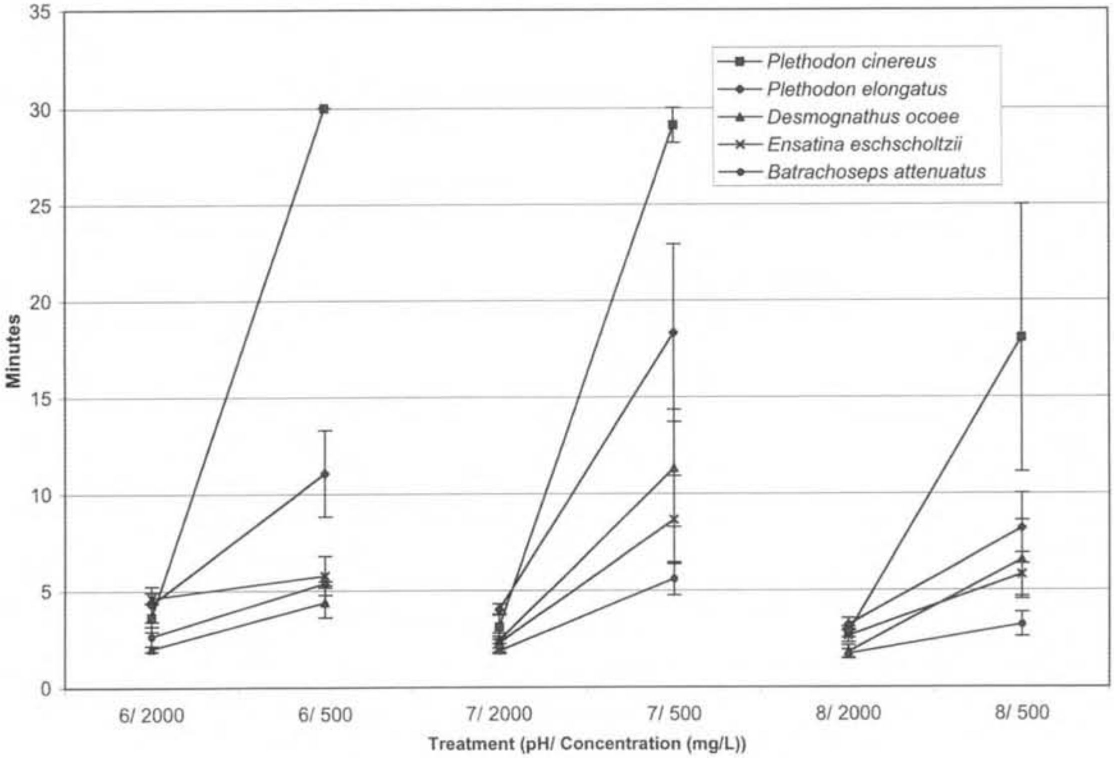

FIG. 1. Mean (± SE, N = 4) times to anesthetization are shown for five terrestrial salamander species under 6 pH/concentration treatments. Treatments consisting of a 2000 mg/L concentration differed from those consisting of a 500 mg/L concentration (ANOVA, p < 0.0001). Treatments made with pH 6 and 7 aqueous buffers differed from those made with pH 8 buffer (ANOVA, p < 0.0001), and *P. cinereus* and *P. elongatus* differed from the other species (ANOVA, p = 0.0001). Standard errors are absent from one treatment because time was cut off at 30 minutes.

stress responses to other pH levels are known. Because increasing pH results in increasing the potency of MS-222, it may be necessary to decrease MS-222 concentrations if one changes their methods from unbuffered to neutral baths. For example, an unbuffered 3500 mg/L MS-222 bath normally used to anesthetize leopard frogs is lethal after being neutralized (Ohr 1975a).

As one would expect, the higher concentration of MS-222 (2000 mg/L) anesthetized salamanders faster than the lower concentration (500 mg/L). At the high concentration, all species were similarly anesthetized in under 5 minutes. At the low concentration, *P. elongatus* and *P. cinereus* took significantly longer (18 and 29 minutes respectively at pH 7) than the other species which took 6–12 minutes at pH 7. These results suggest that while 500 mg/L concentrations of MS-222 work well for some species, 2000 mg/L solutions may be needed for *P. elongatus* and *P. cinereus*. The similarity in response between *P. elongatus* and *P. cinereus* may have a phylogenetic basis due to shared physiological characteristics or may just be a result of random chance. Data on more terrestrial salamanders would be needed to support a phylogenetic hypothesis.

Acknowledgments.—I thank Darrin Doyle for his assistance in the laboratory and edits to the manuscript. I also thank John Reiss for giving his ideas and assistance and Sharyn Marks for use of her laboratory. This work was conducted in accordance with Humboldt State University Institutional Animal Care and Use Protocol #99/00.B.50.B.

A New Method for Attaching Electronic Devices to Crocodilians

WINSTON R. KAY

Despite the potential importance of movement patterns to crocodilian life histories, movement, home range behavior and dispersal have received careful examination only in *Alligator mississippiensis* (Hutton 1989). Data for other species of crocodilian are deficient and stem mostly from mark-recapture studies, which have provided baseline information on many species (e.g., Gorzula 1978; Walsh and Whitehead 1993; Webb and Messel 1978; Tucker et al. 1997). However, telemetry is more suitable for clarifying theories about patterns of movement and advancing our understanding of dynamic activity budgets and seasonal patterns of habitat use by different life-history stages (Tucker et al. 1997).

Radio-telemetry has been successfully used to track *A. mississippiensis* (e.g. Joanen and McNease 1970, 1972; McNease and Joanen 1974; Goodwin and Marion 1979; Rootes and Chabreck 1993), *Crocodylus acutus* (Rodda 1984a), *Crocodylus niloticus* (Hutton 1989; Hocutt et al. 1992), *Crocodylus intermedius* (Muñoz and Thorbjarnarson 2000), *Paleosuchus trigonatus* (Magnusson and Lima 1991), and *Melanosuchus niger* (Martin and da Silva 1998). Attachment configurations for radio tags have included neck collars (e.g. ,Joanen and McNease 1970), tethering (Rodda 1984a; Rodda 1984b; Martin and da Silva 1998; Muñoz and Thorbjarnarson 2000), ingestion (Magnusson and Lima 1991), and surgical implantation (Magnusson and Lima 1991; Hocutt et al. 1992). The most successful methods in terms of longevity have been neck collars (Taylor 1984) and surgical implantation (Hocutt et al. 1992), which have enabled animals to be radio located for periods in excess of 3 and 2 years, respectively. This paper describes a new method used for attaching VHF radio tags to *Crocodylus porosus* that could easily be modified to attach other electronic devices such as satellite tags, GPS data loggers or time-depth recorders.

Captured crocodiles were physically restrained during the attachment procedure by binding the front and rear legs alongside the body with nylon webbing, and tying the animal to an aluminium ladder padded with burlap sacks. Subject animals were blindfolded with eye pads and electrical tape to reduce visual stimulation. Once restrained, the animals rarely struggled during the procedure unless provoked by loud human voices or the sound of an approaching boat. Anesthesia was not used, partly because of difficulty finding an appropriate treatment regimen that effectively and reliably sedated the animals for the intended procedure, but more importantly because of the lengthy recovery periods involved (see Loveridge and Blake 1987; Bennett 1996). Priority was given to returning the animals to the water as quickly as possible at the end of the procedure. The procedure was performed near the site of capture either onboard a small (4.5 m) boat or on the riverbank. Animals were released as close as possible to the site of capture.

Tags were attached to the enlarged nuchal scales on the dorsal

surface of the neck because the pronounced keel of these scales was conducive to the use of bone pins (Fig. 1). The tags fit between the central nuchal scales of large animals (> 3.5 m) and sat above these scales on smaller individuals. One animal had a large gash on its throat and a necrotic wound festering beneath the nuchal scales. Therefore, the tag was attached to the dorsal scales midway between the front legs.

An aluminium angle bracket was pop-riveted to the tag (Fig. 1A), which was then placed over the central nuchal scales to assess the fit (Fig. 1C). Depending on the size of the nuchal scales, the bracket could be trimmed with tin snips as required to minimize the height of the tag above the dorsal surface. The ventral surface of the tag and the bracket were sanded with emery paper to roughen the surface to aid bonding with the glue. The tag was then sprayed with 70% ethanol and allowed to dry.

Two brands of equally satisfactory glue were used: Loctite Fixmaster Underwater Repair Epoxy (<http://www.loctite.com>) or Selleys Knead It Aqua (<http://www.selleys.com.au>). Both are hand kneadable, fast setting, co-extruded epoxy repair systems that come in roll form, with the hardener encapsulated in the resin. They harden 5–10 min. after mixing to a white solid material and cure fully within an hour. Both will adhere to damp or wet surfaces and cure underwater. The glues are slightly exothermic while curing but were tested on human skin and temperatures generated were mild.

The nuchal scales were scrubbed clean with a disposable chlorhexidine scrub, rinsed with river water and dried with a clean cloth. The area was sprayed with 70% ethanol, which was allowed to evaporate. A lump of glue was placed on the ventral surface of the tag, which was then placed between the central nuchal scales. The tag and glue were molded to remove any air pockets and minimize the tag's profile above the dorsal surface while leaving the outside lateral edges of the central nuchal scales exposed to enable the placement of bone pins (Fig. 1B).

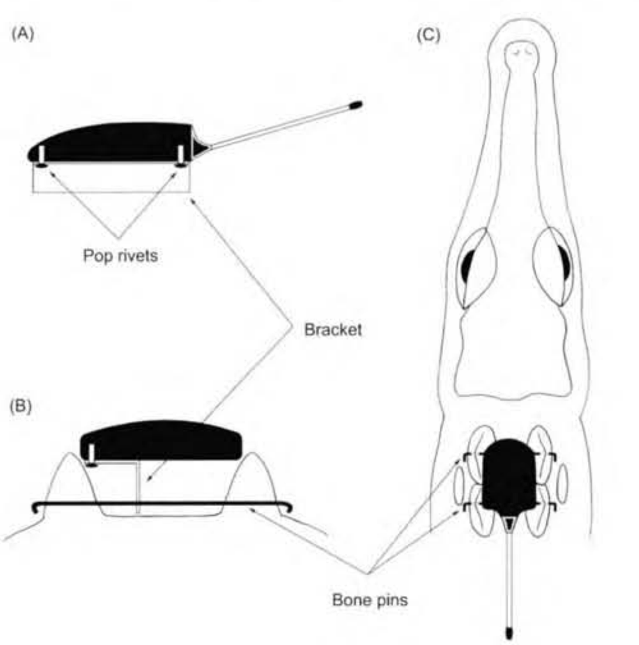

FIG. 1. Placement and orientation of the radio tag, bracket and bone pins on the nuchal scales. The attachment was further augmented with glue, which bonded sufficiently well to the tag and bone pins that the bracket is now considered redundant.

The bone pins used were 31 cm, 1.6 mm diameter, stainless steel Kirschner wires (K-wires), which were cut in half and secured directly into the chuck of a cordless drill. They were then sprayed with 70% ethanol for sterilization. Two pins were used, one through the anterior central nuchal scales and a second through the posterior central nuchal scales (Fig. 1C). The K-wires had a trocar spike at each end, which enabled them to drill directly through the osteoderms and bracket without pre-drilling any holes, but the process was fairly slow. Care was required to ensure the orientation of the bone pins was horizontal and that they penetrated only the raised keel of the scales and the bracket (Fig. 1B). Once the bone pins protruded through the osteoderms they were bent with pliers, to stop them from pulling through, and trimmed with wire cutters (Fig. 1B, C). The area was sprayed again with 70% ethanol, which was allowed to evaporate. Additional glue was then placed around the tag and molded to provide smooth contouring, and totally encase and seal the central nuchal scales, bone pins and the lower half of the tag.

Ten tags were attached using brackets but, because it was thought that the glue bonded sufficiently well to the tag alone, no bracket was used for 6 other attachments (Table 1). The length of time a tag stayed attached to a crocodile was similar, irrespective of whether a bracket was used (15– > 412 days) or not (132– > 370 days), and I now consider the bracket to be superfluous. Elimination of the bracket not only reduced the materials required but also the time taken to attach a tag. Time taken to attach a tag ranged from 60 min. (bracket and inexperience) to about 30 min. (no bracket and experience).

Tag attachment without a bracket was a much simpler procedure. The nuchal area was prepared as before. Holes for the bone pins were pre-drilled through the keel of the nuchal scales with a sterilized drill bit, which was much faster than trying to drill holes using the trocar spike at the end of the K-wires. Also, aligning the bone pins was much easier. After the bone pins were placed through the scales, they were bent and trimmed as before, and the area was then sterilized with 70% ethanol. Once the ethanol evaporated, the glue and tag were placed over the central nuchal scales and molded into place so that the glue enclosed and sealed the bone pins and scales, and held the tag in place.

Every effort was made to use as sterile a procedure as possible, given the limitations of working under field conditions. Because bone pins were used, a single phrophylactic dose of a broad-spectrum antibiotic, oxytetracycline hydrochloride (OTC), was administered by intramuscular injection as a precaution prior to commencement of the attachment procedure. Dose rates were calculated by allometrically scaling the therapeutic dose recommended by the manufacturer for placental mammals, to that for a generic reptile, using the methods described by Pokras et al. (1992) or Sedgwick and Borkowski (1996). OTC has the added advantage of being a suitable biomarker (see Coles et al. 2001). It is worth noting that crocodiles, in common with other reptiles and non-mammalian vertebrates, have a renal portal system. Therefore, it is prudent to inject any medications, especially nephrotoxic drugs, into the anterior half of the animal to avoid the renal portal system (Jenkins 1996).

Tags weighed 140 g but, when combined with glue, pins and bracket, the mass of the assembly increased to about 500 g. In

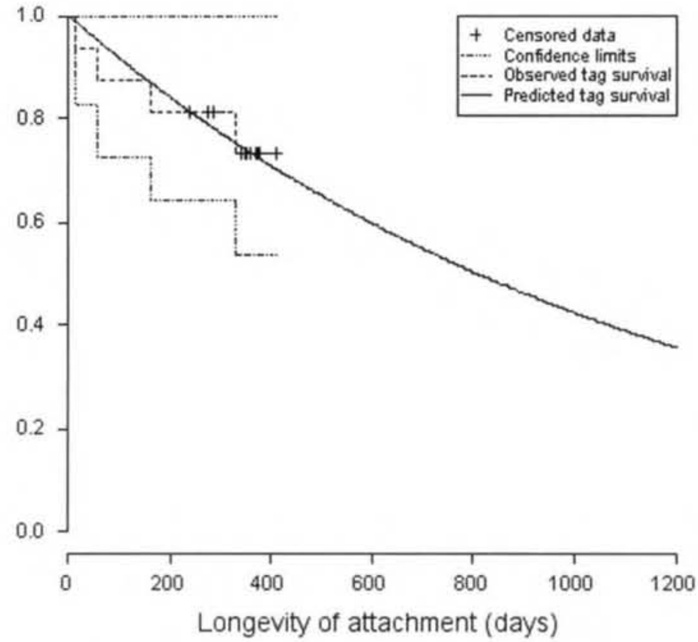

FIG. 2. Exponential survival function fitted to longevity of attachment data. The dashed line is the observed tag attachment time with each step down representing a detachment event. The crosses represent censored data, that is, individuals where the tag was still attached and operational at the final observation. The solid line is the tag attachment time predicted by fitting an exponential function to the observed data.

general, tags should weigh < 3–5 % of body mass to avoid adverse effects (Kenward 2001). Therefore, using this method with current tag specifications, animals would need to be > 17 kg or about 1.8 m total length. The greatest confirmed longevity of attachment (LOA) achieved during the study was > 412 days and most tags remained attached for > 340 days (Table 1). The study ended in May 2003, however, aerial crocodile surveys flown in July 2003 sighted three tagged animals, confirming one tag had remained attached for > 637 days and two others for > 420 days. Four tags (25%) are known to have detached during the study: three detached naturally in submerged snags and one when an animal escaped from a cage trap (Table 1). Dislodgement of a tag is most likely during a flight response when an animal is startled, especially when it is among thick or fallen vegetation, whether submerged or on the bank.

A simple mean LOA would not provide a meaningful estimate of expected attachment time because most tags were still attached and operational at the end of the study (= censored data, see McCallum 2000; Crawley 2002). Therefore, survival analysis on LOA was performed to estimate the mean time to failure using the survival package within R statistical software (ver. 1.6.2, Ihaka and Gentleman 1996). No evidence was found that the risk of detachment increased with attachment time (Weibull distribution, scale = 1.33, $P = 0.5$ for H_0 scale = 1). Therefore, it was assumed that the risk of detachment was constant throughout life, and an exponential survival function was fitted to the data using parametric regression (McCallum 2000; Crawley 2002). The mean time to failure was estimated to be 1164 days. The precision of the estimate was low, having a 95% CI of between 437 and 3103 days, because most of the data were censored with few failures occurring during the study period (Fig. 2).

Crocodile 185 was re-captured after 370 days and the tag removed to evaluate possible deleterious effects of the attachment procedure. The skin appeared healthy with only a slight loss of pigmentation (see Kirshner 1985) and there was no infection or necrosis visible in the underlying tissue. Skull dimensions, total length and body mass had all increased suggesting the attachment

TABLE 1. Longevity of attachment (LOA) achieved for 16 animals tagged during the study.

+ Tag still attached and operational at last fix

had not adversely affected growth or body condition. Furthermore, all females tagged during the study moved to nesting habitat during the wet season and one was detected near a recently constructed nest. Therefore, attachment of the tags did not appear to have interfered with courtship, mating or nesting behavior. On the basis of this evidence, I consider the technique to be relatively benign.

In summary, this technique provides a reliable medium to long-term method for attaching small electronic devices to crocodilians. It has some advantages over other successful methods of tag attachment. First, it does not constrict an animal's neck as would a collar and it is not as invasive as surgical implantation. Also, signal propagation is better than with an implanted tag, which improves detectability. Examination of underlying tissue on one animal 370 days after attachment suggests that the method is relatively benign. There are a number of ways the technique could be refined. Ideally, the tag should have as low a profile as possible above the dorsal surface of the animal. In hindsight, it would have been preferable to design a narrower tag that would fit between the central nuchal scales on a greater size range of animals to reduce the overall profile of the tag assembly above the dorsal surface. However, there is a compromise in that the tag itself would have a higher profile. Additionally, the flexible whip antenna could be orientated vertically without greatly increasing the risk of detachment, which may improve signal propagation and reception (see Kenward 2001). The use of alternative materials may also be advantageous. For example, bone pins made from titanium or Delrin plastic (<http://plastics.dupont.com>) are probably more inert than stainless steel. It would be well worth testing the use of a less dense, flexible polyurethane glue such as Sikaflex-291 (<http://www.sika-industry.com>), which would reduce the overall weight of the tag assembly. However, curing times for this product are lengthy and would need to be accelerated to be of practical use in the field.

Acknowledgements.—This work was funded by the Department of Conservation and Land Management and Lotterywest through a Gordon Reid Foundation grant to the Save Endangered East Kimberley Species (SEEKS) community group of Kununurra. In addition, I would like to thank Nick Gales, Rick Read, Rob Day, Paul Clarkson, Sarah Brett, Grahame Webb and Gordon Grigg for useful discussions on potential methods and materials for attaching transmitters. Thanks also to Jane McRae for drawing the illustrations in Fig. 1, Hamish McCallum for advice on statistical procedures and Charlie Manolis for reporting tagged animals sighted during aerial surveys.

A Novel Technique for Capturing Arboreal Geckos

NICHOLAS C. COLE
*School of Biological Sciences, University of Bristol
Woodland Road, Bristol BS8 1UG, United Kingdom
e-mail: nik.cole@bristol.ac.uk*

When conducting research on lizards it is often necessary to capture individuals unharmed. Popular methods for the capture of arboreal lizards include hand capture, noosing, using rubber bands as projectiles (Simmons 1987), chasing lizards into mesh barriers (Patterson 1998), attracting individuals to baited traps (Durden et al. 1995; Zani and Vitt 1995), or fishing for them with baited lines (Krysko 2000; Strong et al. 1993). Other methods include using wire hooks to pull lizards from refugia (Bedford et al. 1995), glue boards for passive capture (Bauer and Sadlier 1992), or sticky poles for active capture (Durtsche 1996).

Any capture technique has inherent problems (Krysko 2000), but for the capture of small, skittish, and fast-moving lizard species, such as geckos that perch high on building walls, the techniques listed above make capture without harm extremely difficult and, in many cases, inappropriate. The most suitable of these techniques is noosing, but often the lizard flees at the sight of the approaching pole, evades the noose, or bites the noose pulling it closed (pers. obs.). Furthermore, the thread of the noose has to be thin, making it difficult to see more than 3-m away and difficult to keep steady. Using a baited line poses similar problems to using a noose.

To overcome the problems of safely catching arboreal geckos from buildings, I describe a novel technique I developed to capture native and introduced geckos in Mauritius using a laser pointer.

All geckos rely on their vision to capture predominantly insectivorous prey and are, in general, opportunistic feeders, attacking any small moving object within range. A small dot projected onto a wall from a laser pointer within view of a gecko will entice the lizard to give chase and repeatedly lunge and bite at the dot. The dot can then be moved down the wall to a point permitting capture, generally at chest height, close to an awaiting hand. To keep the gecko moving it is necessary to keep the laser dot within 5–10 cm of the gecko's head.

Lasers are grouped into seven classes (1, 1M, 2, 2M, 3R, 3B, and 4), the higher the class the greater risk of laser radiation hazard. Most commercially available laser pointers belong to Class 1 or 2. The output power of a Class 1 laser is such that exposure of the eye to the beam will not cause damage and is, therefore, considered eye safe. The output power of a Class 2 laser is higher and prolonged eye exposure is potentially harmful, although a person's natural involuntary response, such as the blink reflex and/or head aversion is quicker than the maximum permissible exposure time, therefore avoiding damage to the eye. The International Electrotechnical Commission (IEC 60825–1 2001) and British Standards (BS EN 60825–1 1994) state that only Class 1 or 2 devices should be used in unsupervised areas. Of course, when using any type of laser pointer, do not shine the laser beam into the eyes of any person or animal. The risk of shining the beam of the laser into the eyes of a gecko is easily avoided by continually moving the laser away from the target animal. Catching geckos from reflective surfaces, such as glass windows, should be avoided. Researchers, should consult regional laws and regulations before undertaking fieldwork using laser pointers because some countries have laws associated with possession and use of laser pointers.

The efficiency of the technique is illustrated for four species of nocturnal gecko and the daytime capture of two diurnal species (Table 1). The laser pointer was only used for geckos that could not be caught by noose or by hand. Individual geckos were not captured more than once for this trial. The utility of this method, therefore, is untested for experimental designs requiring multiple captures of the same individual. More than 90% of all geckos pursued the laser dot and almost 80% of these were brought to a point of capture. Five geckos were so intent on eating the laser dot that they chased the dot down onto the ground (up to 11 m) and two were coaxed onto the palm of my hand. Of the 19 geckos that were not brought to a point of capture, seven showed no response to the laser dot, one ran off, six terminated their pursuit after chasing the laser dot (one after pursuing it for 8 m), and five either encountered and ate an insect or were chased off by another gecko whilst following the laser dot.

Nocturnal geckos responded similarly in chasing the laser dot over unlit (51%) and lit (49%) walls and over smooth (cemented/bricked [58%)]) and rough (old stone [42%]) walls. All diurnal geckos were found on shaded walls. It is doubtful whether geckos would be able to see the laser dot in full sunlight. Eighty six percent of diurnal geckos were found on smooth surfaces, so it is difficult to determine whether wall texture had an effect on efficiency of laser use.

This technique is quick to use, inexpensive, requires minimal equipment, and aids in the capture of individuals from high, unreachable places without harm. The use of the laser pointer has also been successful in enticing adult *Phelsuma ornata* down the trunks of coconut trees (data not included here), indicating that its use may not be restricted to relatively flat surfaces, such as walls.

TABLE 1. Number of each lizard species indicating the percentage of adults (rounded to nearest whole digit), the efficiencies of the laser technique, and distances they moved.

Species	N	Geckos chasing laser dot (%)	Brought to hand capture (%)	Mean distance (m) moved by responsive geckos (SD, maximum)
Gehyra mutilata	9	78	78	4.3 (1.1, 6)
Hemidactylus brookii	7	100	86	6.1 (2.3, 9)
Hemidactylus frenatus	58	97	85	4.4 (2.2, 11)
Hemiphyllodactylus typus	3	67	33	3.5 (0.7, 4)
Phelsuma cepediana	3	67	67	3.5 (0.7, 4)
Phelsuma ornata	14	86	71	3.3 (1.7, 6)
Total or Mean (%)	94	92	80	4.3 (2.1, 11)

This method is also likely useful in facilitating the capture of other small insectivorous lizards. Another potential use could be in social experiments wherein an individual is enticed into the territory of another to test behavioral interactions.

Acknowledgments.—This technique was developed under a NERC grant NER/S/A/2001/05996 and a grant from the Zoological Society of Wales. I thank S. Harris and C. Austin for their comments and improvements of the manuscript.

A New Method for Preparing Preserved Hemipenes of Lizards for Scanning Electron Microscopy

Lizard hemipenis morphology has a long history of use in taxonomy (e.g., Arnold 1986a, b; Branch 1982; Cope 1895, 1896). In other taxa the morphology of intromittent organs has also provided valuable insight into the mating strategies of a species (Arnqvist 1997; Arnqvist et al. 1997; Dixson 1987; Eberhard 1985; Patterson and Thaeler 1982). Thus, detailed studies of hemipenis morphology can be useful in a number of research fields.

Investigations of hemipenis morphology are best made on freshly prepared material, as this minimizes the potential for artifacts and allows the natural shape of the organ to be studied. Unfortunately, fresh material is not always readily available and researchers often must rely on material from museum specimens.

Squamate hemipenes are particularly difficult to study once preserved, as they lie in an inverted state within the base of the tail when not erect. Consequently, to observe their structure and surface features, it is necessary to evert these organs. This is best done at the time of preservation because fixation tends to harden tissue, making it difficult to evert fixed hemipenes without causing damage to their structure. As a result, it is common for researchers to dissect inverted organs of preserved specimens *in situ* to investigate their surface features (e.g., Arnold 1973; 1986a; Böhme 1988; Dowling and Savage 1960). The disadvantage of this method is that it provides little insight into the overall structure of the everted organ.

More recently, Pesantes (1994) described a method for softening fixed snake hemipenes by soaking the material in a 2% solution of potassium hydroxide (KOH) for 3 d. We tested this technique on eight species of New Zealand geckos but found that it led to tissue damage. In this paper we report these results and describe a new technique for softening fixed hemipenes that is easy to use and causes little tissue damage.

As part of a comparative study on interspecific variation in hemipenis morphology of New Zealand geckos (Gekkonidae), we initially followed Pesantes' (1994) method to soften the inverted hemipenes of 16 museum specimens belonging to eight gecko species that had been fixed in formalin. The condition of the fixed specimens was compared with the hemipenes of six *Hoplodactylus maculatus* that had been preserved in ethanol and did not require any treatment prior to eversion because the hemipenial tissue had remained soft and pliable.

The preparation history of the 16 museum specimens used in our study was uncertain, but all had been fixed in formalin (concentration and duration unknown) and stored in 70% ethanol. The specimens had been stored for 19–35 yr. Hemipenes were first dissected in their entirety from the base of the tail (following Arnold 1986a). Samples were rehydrated from 70% ethanol to distilled water in decreasing concentrations of ethanol (50 and 30%), by soaking the tissues for a minimum of 1 h at each concentration. The hemipenes were then softened using KOH (Pesantes 1994). We found that samples ($N = 6$) that had been soaked in a 2% solution of KOH for 3 d either partially or totally disintegrated. Therefore, we modified this method and obtained best results when the hemipenes were soaked in a 1% solution of KOH for 5–11 h. Following softening, hemipenes were rinsed in 0.05N HCl for 10 min and soaked overnight in distilled water. Specimens were then everted in distilled water using round-tipped forceps and a blunt probe to push the lobes inside out. It is usual for researchers to inflate everted hemipenes to obtain maximal turgidity (e.g., Böhme 1988; Glaw et al. 1999; Myers and Cadle 2003; Zaher and Prudente 2003). However, the degree of inflation that naturally occurs is unknown and it is thought that organs are often over-inflated (Arnold 1986a). In addition, it is difficult to standardize the amount that an organ is inflated. Consequently, for interspecific comparisons in which the surface features rather than the size of the organ are of primary interest, it is preferable to avoid this procedure if possible. Because the hemipenes of the species studied were very small, the organs could be fully everted with relative ease, allowing the surface features to be observed without inflation.

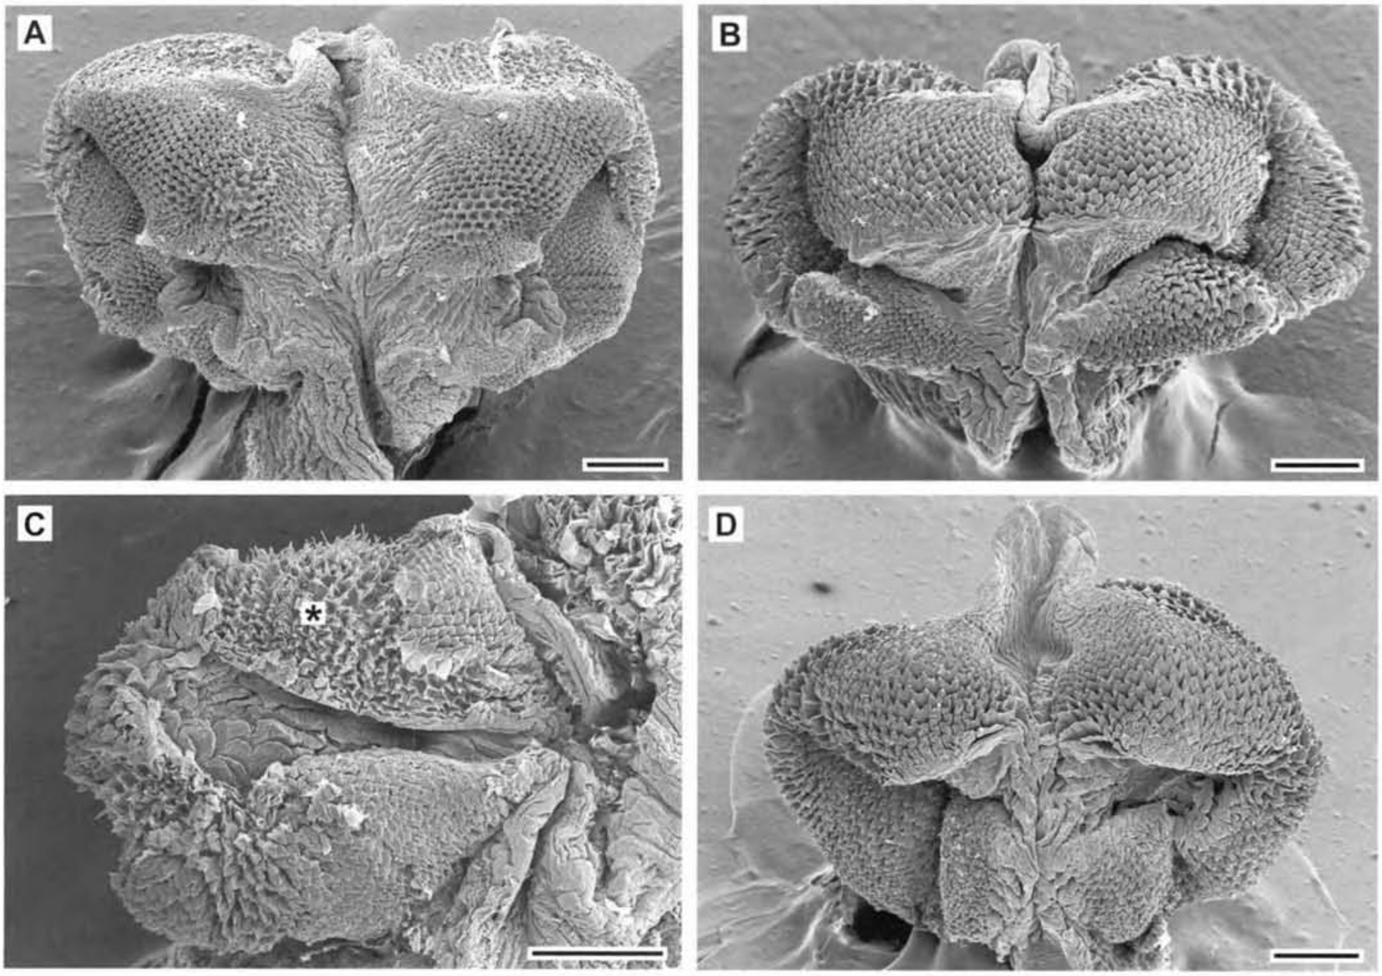

FIG. 1. SEM micrographs of the sulcal surface of hemipenes of *Hoplodactylus maculatus* (Gekkonidae) prepared using different treatments: (A) specimen softened in 1% KOH; (B) untreated ethanol-stored sample; (C) single lobe of hemipenis damaged when softened in 1% KOH, note loss of calyces (*); (D) saponin-prepared sample. Scale bars = 500 µm.

Following eversion, the hemipenes were fixed in 2.5% glutaraldehyde and 1% paraformaldehyde in 0.1M sodium cacodylate for 3 d. Samples were then prepared for scanning electron microscopy (SEM) using the following procedure: washed overnight in 0.1M sodium cacodylate buffer, stained in 2% osmium tetroxide (OsO_4) in distilled water for 2 d, soaked in distilled water for 2 h, dehydrated through an ethanol series (30, 50, 70, 80, 90, 95, and 100%) for a minimum of 2 h at each concentration, left overnight in fresh absolute ethanol, placed in a four-step increasing concentration gradient of amyl acetate in ethanol (25, 50, 75, and 100%) for a minimum of 2 h at each concentration, left overnight in pure amyl acetate, critical point dried with liquid CO_2, mounted on aluminium SEM stubs using conductive carbon paint, and sputter-coated with ca. 40 nm gold/palladium. Hemipenes were viewed using a LEICA S440 scanning electron microscope at accelerating voltages of 10–20 kV.

The use of KOH to evert fixed hemipenes gave variable results. Of the 16 samples, four were everted in excellent condition (Fig. 1A), equal to that of unfixed specimens that had been stored in ethanol and did not require any treatment prior to eversion (Fig. 1B). However, for the remaining samples the KOH treatment resulted in partial or complete loss of the surface layer of calyces (Fig. 1C). Glaw et al. (1999) also found that KOH was sometimes too harsh for delicate organs. Accordingly, we concluded that a milder softening agent was required.

Detergents have been used previously to partially recover formalin-fixed material (Humason 1962). Maupin and Pollard (1982) demonstrated that the permeability of cell membranes to fixatives and stains could be improved by soaking the tissue in saponin, a plant glycoside with detergent-like properties that is extracted from the bark of *Quillaja*. We tested whether saponin (Sigma Cat. # S4521) could soften formalin-fixed hemipenes and enable us to evert them more easily and with less damage than we experienced with the KOH treatment.

We dissected and rehydrated hemipenes from 22 specimens belonging to 10 gecko species using the methods described previously and then soaked them in a 1% solution of saponin in distilled water. The samples were checked at 15-min intervals to detect the best time for eversion using a blunt probe to test the material for optimal softness and pliability. We found that the organs regained sufficient flexibility for eversion after 1–2 h in the saponin solution. The hemipenes were then everted, rinsed 3–5 times in distilled water over a 30-min period and prepared for SEM as described above.

Saponin treatment yielded excellent results in 16 out of 22 samples (Fig. 1D), comparable to the most successful KOH-pre-

pared specimens and the ethanol-stored samples. Although the minimum soaking time required to sufficiently soften the material varied between samples (presumably a function of their original collection/storage regime), there appeared to be no risk of over softening the tissue and thus losing delicate surface features. Only in six samples did saponin fail to soften the organs sufficiently to evert them. In these instances the tissue had been left in the solution for 2.5 h and appeared to have regained sufficient flexibility for eversion. However, upon attempting eversion we found that the material crumbled, as the tissue inside was still hard and brittle. Longer soaking times may have been required for these samples, or some samples simply may not be reclaimable using this method.

The use of fixed material to investigate the surface features of squamate hemipenes may always be, at best, a salvage operation. This is often necessary because of the lack of suitably preserved specimens. We found that saponin is a highly effective softening agent of formalin-fixed material, as not only are preparation times relatively short, but the treatment is also very mild to the tissue. Consequently delicate structures on the surface of the organ are retained throughout processing. It is possible that other solutions with detergent-like properties may prove successful in salvaging similarly preserved tissues.

Acknowledgments.—We are very grateful to R. Coory for permission to dissect preserved specimens from the Museum of New Zealand Te Papa Tongarewa, and T. Whitaker and B. Thomas for the provision of ethanol-stored specimens of *Hoplodactylus maculatus*. We also thank J. Briskie, H. G. Dowling and an anonymous reviewer for critical comments on the manuscript. This research was funded by a Brian Mason Trust grant and the Shirtcliffe Fellowship. A. Todd was supported by a Foundation for Research, Science and Technology Top Achiever Doctoral Scholarship.

Recognition of nutritional metabolic bone disease (= nutritional secondary hyperparathyroidism) in herpetocultural collections in recent decades has led to an interest in measuring ultraviolet B (UVB) radiation (280–315 nm) in natural light and in vivaria illuminated with artificial lamps. UVB facilitates photoisomerization of 7- dehydrocholesterol (pro D_3) to previtamin D_3 (preD_3) which in turn is thermally isomerized to vitamin D_3 (vitD_3) (Chen 1999;

* less than lower limit of detection

Holick 2004). The irradiance of UVB is related to the rate of $preD_3$ production and hence indirectly to the rate of $vitD_3$ synthesis.

Spectroradiometers can accurately measure the irradiance of UVB from a light source. However, they are expensive and relatively difficult to work with. Hand-held broadband radiometers are less expensive and easy to use but may indicate irradiances that are significantly different from the actual values. Gehrmann et al. (2004) examined three types of broadband radiometers and showed that the meters indicated different levels of irradiance from the same light source. The determination of the vitamin D_3-photosynthesizing ability of a light source can serve as an independent measure of UVB irradiance. Thus, the percentage of photoproducts formed from $proD_3$ after exposure to the light for a specified time period allows for the comparison of irradiances from the different meters.

We recently became aware of an inexpensive broadband UVB meter manufactured by Solartech, Inc. (Harrison Township, Michigan 48045) as model no. 6.2, reading UVB between 280 and 320 nm and with a resolution of 1 $\mu W/cm^2$. In order to facilitate comparisons with the three meters described by Gehrmann et al. (2004) (Gigahertz-Optik, Inc. [Newburyport, Massachusetts 01950], UVP, Inc. [Upland, California 91786], and Spectronics Corp. [Westbury, New York 11590]) we correlated irradiances and associated doses from natural sunlight and various lamps with in vitro $vitD_3$-synthesizing ability.

Measurements of UVB in natural light at different times of the day were made in Boston, Massachusetts during the four seasons of 2003. UVB irradiance readings for the 1 hour during which $proD_3$-containing ampules were exposed were recorded at the start, middle, and end of the hour and then averaged. Readings were made at a solar angle of 80°. Irradiances from the three 20-watt fluorescent lamps were recorded at various distances below the midpoint of the lamp length; the meter was slowly moved about at this location to achieve the maximum reading. Irradiances were recorded at various distances below the center of the light circle produced by the Westron mercury vapor lamp. $ProD_3$ ampules were placed at these positions and exposed for 2 h to maximize conversion.

After exposure to the light source, the boron-silicate ampules that had contained 50 µg of $proD_3$ dissolved in one ml of ethanol

were analyzed by High Performance Liquid Chromatography (HPLC) for proD_3 and UVB-induced photoproducts (preD_3, tachysterol, and lumisterol) and vitD_3. A Waters 501 HPLC pump was used in conjunction with a Waters 490E multiwave detector set at 260 nm. The column was Econosphere silica, 5 µm, 250 x 4.6 mm (Alltech Associates, Inc, Deerfield, Illinois). The mobile phase was 8% ethyl acetate in hexane with a flow rate of 1.8 ml/min. Three replicates per ampule were analyzed and the percent of photoproducts and vitD_3 synthesized was calculated (see Gehrmann et al. 2004 and Webb et al. 1988 for details of the HPLC procedure).

We wished to verify that comparisons of photoproduct formation between the natural light ampules exposed for one hour and those exposed to the lamps for two hours were valid. The reciprocity law (Parrish et al. 1978) states that the UVB effect on photoproduct formation is not from irradiance *per se* (i.e., rate of energy delivery as watts), but rather the total energy (joules) delivered during a given time period which is the dose [dose (mJ/cm^2) = irradiance (µW/cm^2) x time (seconds) ÷ 1000]. We selected three different exposure times (30, 60, and 120 minutes) and adjusted the irradiance from a lamp, by changing the distance, such that the delivery dose was the same for all three periods. If the law was applicable to this study, the percent of photoproducts formed in the ampules should be the same for the three exposure times.

Results (Table 1) demonstrate the validity of the reciprocity law and justify comparisons of doses and associated photoproduct synthesis between ampules exposed to natural light for one hour with those exposed to various lamps for two hours. This idea is embodied in the regression equations relating the percent of photoproduct formed to the UVB dose (not the irradiance) that are given in Tables 2 and 3. Table 2 shows the irradiances of UVB in natural light in Boston measured with a Solartech 6.2 meter, and the associated doses, and relates them to the percent of photoproducts formed in ampules after one hour of exposure. Daily and seasonal trends are evident. Table 3 contrasts the UVB irradiances at different distances from four lamp types commonly used in herpetoculture and indicates their ability to produce vitD_3 photoproducts in ampules exposed for two hours. It is evident that the same irradiance and associated dose from different lamps can produce different quantities of photoproducts. Not all wavelengths within the UVB band are equally effective in producing preD_3 from proD_3. The greater the percent photoproduct formed at a given dose, the greater the concentration of UVB energy clustered around the most effective wavelength of 295 nm. This is clearly demonstrated by the Westinghouse FS 20 UVB lamp in Table 1. The percent of photoproducts formed is considerably higher than for the other light sources described in this article because of the high concentration of UVB close to 295 nm.

Evaluating the significance of vitD_3-synthesizing potential for herpetocultural purposes remains largely unexplored. Systematic studies showing the effect of latitude on the ability of natural light to form photoproducts in ampules could serve as an estimate of UVB requirements for various species in captivity taken in the context of their natural history and habitat preferences. Scattered reports indicate significant latitudinal effects on vitD_3-synthesizing ability. Webb et al. (1988) reported ampule conversions of 3% in Los Angeles, California (34°N) and 10% for Puerto Rico (18°N), both in January. Gehrmann et al. (2004) report conversion at about 11% at noon in Boyd, Texas (32°N) in September. Conversion at Iquitos, Peru (3°S) was about 15% in February (Gehrmann, unpubl. data). Ampule photoproduct formation was characterized throughout the year in Edmonton, Canada (52°N) by Webb et al. (1988). Additional examples can be found in Chen (1999) and Holick (2004).

Knowing the UVB requirements for a species studied in captivity allows for more specific recommendations. For example, Ferguson et al. (2002) reported that lamps that produce conversions from 0.52% to 1.32% after a 2 h exposure when used for 12 h per day, facilitate the production of viable hatchlings in the panther chameleon. Conversion percentages above or below these values resulted in reduced hatchability of viable eggs. Referring to Table 3 and using the regression equations, we see that a blacklight with an irradiance of between 5 and 11 µW/cm^2, a Reptisun 5.0 between 15 and 33 µW/cm^2, an ESU Desert 7% between 20 and 42 µW/cm^2 and a Westron spot between 8 and 35 µW/cm^2 will produce conversions within the 0.52% to 1.32% range. It is suggested that further studies relating UVB irradiance to husbandry and reproduction in reptile species, especially lizards, will contribute to their captive welfare.

The percent of photoproduct formation in ampules can serve as a reference to doses and associated irradiances measured with other meters. For example, from Table 3 we see that for a Sylvania 350 blacklight the amount of photoproduct formed is 1.34% when the irradiance is 13 µW/cm^2. Using the data in Gehrmann et al. (2004) it can be calculated that 1.34% is associated with an irradiance of 7 µW/cm^2 measured with a Gigahertz-Optik meter, 80 µW/cm^2 measured with a UVX meter, and 17 µW/cm^2 measured with a Spectroline DM 300N meter.

The Solarmeter sensor and processor are combined as a single unit. Because the sensor is located about 10.5 cm above the meter bottom, it cannot be used to directly measure the irradiance at the substrate level in an enclosure. Nevertheless, this meter will be useful for many purposes, including monitoring the UVB output of various lamps or checking the attenuation of UVB by various materials.

Herpetological Review

Volume 35, Number 4 — December 2004

Herpetological Review

The Quarterly News-Journal of the Society for the Study of Amphibians and Reptiles

Society for the Study of Amphibians and Reptiles

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2004 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Department of Biological & Environmental Sciences, Western Connecticut State University, 181 White Street, Danbury, Connecticut 06810, USA. Fax: (203) 837-8769; e-mail: PinouT@wcsu.edu.

Future Annual Meetings

2005 — University of South Florida, Tampa, Florida, 6–11 July (with ASIH, HL)
2006 — New Orleans, Louisiana, 12–17 July (with ASIH, HL)

About Our Cover: *Phyllomedusa tomopterna*

Phyllomedusine frogs comprise six genera and 52 species that range, collectively, from Mexico through Argentina (Frost 2004. Amphibian Species of the World: an Online Reference. Version 3.0 [22 August, 2004]. Electronic database accessible at http://research.amnh.org/herpetology/amphibia/index.php. American Museum of Natural History, New York). All but one species (*Phyllomedusa atelopoides*) are arboreal. These frogs usually resemble some shade of green foliage, and are adapted to highly desiccating canopy environments in tropical climes. Most conserve moisture by wiping themselves with dorsal lipid secretions and passing the day sleeping, with limbs pressed to the body. Some phyllomedusines such as *Pachymedusa dacnicolor*, *Phyllomedusa hypocondrialis*, and *P. sauvagii* have exploited seasonally dry thornscrub and savanna habitats. The genus *Agalychnis* (Leaf Frogs) includes the Red-eyed Leaf Frog (*A. callidryas*), perhaps the most photographed amphibian in the world. The genus *Phyllomedusa* (Monkey Frogs) includes the Giant Monkey Frog (*Phyllomedusa bicolor*), that secretes peptides sequestered by Matses Indians and used to enhance their vision and hearing while hunting game (Daly et al. 1992. Proc. Nat. Acad. Sci. USA 89:10960–10963). Leaf and Monkey frogs are unusual in that they hop and crawl slowly as opposed to leaping. Their habit of grasping at perches is more reminiscent of chameleons than frogs. When molested, most phyllomedusines simply tuck their limbs, close their eyes, and remain motionless. A distinctive odor is given off by several species, but its function has not been demonstrated.

Breeding aggregations of some species (*Agalychnis spurrelli*, *Phyllomedusa bicolor*) may involve dozens of raucous individuals. By contrast, the Amazon Leaf Frog (*A. craspedopus*) is nearly silent and visits water-filled stumps and tree holes to reproduce. Phyllomedusine eggs are laid in gelatinous masses on vegetation overhanging water. Tadpoles fall from the ooze into the water to complete development. Eggless capsules and rolled-leaf nests serve to provide metabolic water and impede desiccation, respectively, for *P. hypocondrialis* eggs (Pyburn 1980. Proc. Biol. Soc. Washington 93:153–167). Populations of *P. tomopterna* in Brazil suffered 67% egg mortality from predation by phorid flies and staphylinid beetles (S. Neckel-Oliveira and M. Wachlevski 2004. J. Herpetol. 38:244–248).

The Barred Monkey Frog (*Phyllomedusa tomopterna*) on the cover was photographed at night in primary rainforest at the Allpahuayo-Mishana Reserve in Loreto, Peru, not far from the type locality (Cope 1868. Proc. Acad. Nat. Sci. Philadelphia 20:112). This species is found throughout Amazonian and Guianan South America. It is distinctive owing to the pronounced calcars (dermal heel appendages) and brightly colored flanks. **William W. Lamar** took the picture with a Pentax LX camera, Vivitar Series 1 105mm macro lens set at f22, Vivitar Series 1 flash, using Fujichrome Velvia film rated at ISO 80 and pushed 1 stop during processing. Lamar spends much of his time in the tropics, guiding groups for GreenTracks, Inc. (www.greentracks.com), or coordinating film work for the Discovery Channel, Animal Planet, and the BBC.

SSAR BUSINESS

Dean E. Metter Memorial Award Winner 2004

Sixteen very well written proposals were submitted for the first Dean E. Metter Memorial Award. Committee members (Joseph Beatty, Anne Maglia, and Brian Miller) were extremely impressed with all of the proposals, but had to choose a single awardee. We have chosen Alison Hamilton Jennings to be the second recipient of the Metter Award. Her proposal was titled: "Comparative Phylogeography of Two Lizard Families with Differing Life Histories, Ecologies, and Reproductive Modes."

Ms. Jennings earned a B.A. in Ecology from Simon's Rock College (Great Barrington, Massachusetts) in 1993. Her undergraduate thesis work dealt with *Chrysemys picta* and *Chelydra serpentina* and was supervised by Robert Schmidt and David Meyers. In 2001, she earned an M.S. in Wildlife Ecology & Conservation with Kenneth Dodd at the University of Florida. Her thesis was entitled: Evidence for Ontogenetic Shifts in Box Turtles: Activity Patterns, Movements, and Use of Microenvironments and Habitats by Juvenile *Terrapene carolina bauri* on Egmont Key. Alison is well into her doctoral work with Christopher Austin at Louisiana State University in Baton Rouge with the completion of two successful field seasons. Her thesis work compares the phylogeography of geckos (*Nactus pelagicus*) and skinks (*Emoia sanfordi*) in the Vanuatu Archipelago.

2005 Dean E. Metter Memorial Award Application Deadline 28 February 2005

The Dean E. Metter Memorial Award is given annually by SSAR to a herpetology student. Its purpose is to encourage students to pursue field research in herpetology and to facilitate field research by providing funds for relevant expenses. Proposals must be submitted (post-marked) no later than 28 February to be considered; 2005 SSAR dues must be paid by 31 December 2004. Failure to meet these guidelines may result in elimination of a proposal from consideration. Awards will be announced on or around 1 April. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review*, or to present their findings at the annual meeting of the SSAR. Full proposal guidelines, submission instructions and background information are available on the SSAR website (http://www.ssarherps.org/pages/metter.html).

Proposals should be submitted electronically as e-mail attachments or by regular mail. Submit proposals or questions regarding application procedures to the Chair of the Metter Award Committee, Dr. Joseph J. Beatty (beattyj@science.oregonstate.edu). Awards will be announced on or around 1 April 2005.

2004 Annual Meeting, Norman, Oklahoma

The 47th annual meeting of SSAR took place from 26–31 May 2004 at the National Center for Employee Development (NCED)/ Marriott Conference Center in Norman, Oklahoma. SSAR members joined with members of the American Elasmobranch Society (AES), the American Society of Ichthyologists and Herpetologists (ASIH), and The Herpetologists' League (HL). The meeting was hosted by the University of Oklahoma with local organizers from the Sam Noble Oklahoma Museum of Natural History, the Department of Zoology, and the Oklahoma Biological Survey.

Almost 1100 herpetologists (including the amazing 94-year-old Henry Fitch) and ichthyologists from 21 countries attended the meeting; 43% of the attendees were students. Papers and posters were presented by 610 individuals. Although the number of symposia was down this year (only four compared to 11 in 2003), they were well attended. The very successful symposium honoring Eric Pianka was standing room only at times.

A great deal of thanks is due to Janalee Caldwell (Chair) and other members of the Local Committee for their dedication and hard work. Manaus was always going to be a hard act to follow, but they rose to the challenge! Special thanks are due to Sharon Brookshire, Jan Hudzicki, and their staff from the Kansas State University Division of Continuing Education for their superb organizational skills.

Social Programs and Resolutions

On the evening of 26 May, President Janalee Caldwell introduced Dr. Rafe Brown (Berkeley and University of Kansas) who gave this year's SSAR President's Travelogue "Oceanic Islands, Cloud Forests, Marcos' Ghost, and Herpetology in the Philippines." As has become the tradition, the room was full and an appreciative audience enjoyed hearing about the biology of the diverse herpetofauna in this biologically rich area, as well as stories about the trials of field work in a tropical region.

President Caldwell opened the Plenary Session on 27 May by welcoming meeting participants to Norman. Ellen Censky (Director, Sam Noble Oklahoma Museum of Natural History) and T.H. Lee Williams (Dean of Graduate College and Vice President for Research, University of Oklahoma) reiterated the welcome and gave informative presentations about the Museum and the University. This was followed by the ASIH Past-Presidential Address from Larry Page, "Egg-clustering and Diversification in Darters." Eric Pianka was this year's Distinguished Herpetologist for The Herpetologists' League and gave a presentation entitled "Can We Read the Vanishing Book of Life?" The AES Plenary Address "Life After Jaws: The American Elasmobranch Society, 20 Years and Counting," given by Samuel Gruber and John Morrissey, completed the Plenary Session.

The Annual Group Photograph followed the morning Plenary Session and many meeting attendees dutifully assembled outside. However, this year, thanks to modern technology and some creative editing, showing up for the photograph didn't necessarily guarantee that your face would appear once, twice, or even at all! The General Reception was held that evening in the Sam Noble Oklahoma Museum of Natural History. Many enjoyed viewing an exhibit of stunning photographs of Brazilian herpetofauna taken by herpetology curators Janalee Caldwell and Laurie Vitt, entitled "Amazonian Biodiversity: Through the Eyes of Amphibians and Reptiles."

Tornado warnings and predictions of wild weather drove the Annual Picnic indoors. Although we were spared, some 92 tornadoes touched down in a band to the north and east that evening, as Oklahoma and Kansas lived up to their reputations. We enjoyed plenty of good Oklahoma barbeque and some great music from "Harvey and the Wallbangers." The Annual SSAR/HL Live Auction held on Sunday evening was, as usual, well attended. John Moriarty's skill as an auctioneer successfully pushed up the bidding on a number of items. Particularly frenzied was bidding on a bottle of 10-year-old beer from the First World Congress of Herpetology and a 5-liter bottle of chardonnay wine donated by Toad Hollow Winery.

The Annual Banquet was held on 31 May at the Sam Noble Museum with Dave Hillis serving as the Master of Ceremonies. Dave warmed up the crowd with a presentation of an impressive collection of photographs amassed throughout the meeting. Who knew that James Dean and Marilyn Monroe would one day attend the Joint Meeting? Winners of the Henri Seibert and Kennedy Awards were acknowledged at the banquet.

The following resolutions were read by Linda Ford (Chair, SSAR Resolutions Committee) and David Green (Chair, ASIH Resolutions Committee) at the banquet:

Resolution on the SSAR Presidents' Travelogue speaker:
Whereas, SSAR President Janalee Caldwell invited Dr. Rafe Brown to present the 2004 SSAR Presidents' Travelogue, and,
Whereas, despite the presence of Marcos' ghost, nothing went awry with the equipment nor facilities, and,
Whereas, Dr. Brown tragically revealed that the exciting new species just discovered are already in danger of extinction from habitat destruction,
Therefore be it resolved that Dr. Brown presented an insightful, fact-filled, but none-the-less enthralling performance despite the fact that he is not on the job market.

Resolution on the SSAR Conservation Committee:
Whereas, the April issue of The Ecological Society of America's publication *Frontiers in Ecology and the Environment* describes SSAR as "the largest international herpetological conservation society", and,
Whereas, the article describes the informative and exciting features of the Conservation committee's new website,
Therefore be it resolved that the society thanks Stephen Richter, chair of the committee, and all members of the conservation committee for their excellent work and for bringing recognition to SSAR.

Resolution on Outgoing SSAR Officers, Editors, and Others:
Whereas, the following individuals have given freely of their time, energy, and expertise to SSAR, and,
Whereas, because of their hard work and dedication, SSAR programs, projects, and goals have been advanced, and,
Whereas, SSAR is dependent on the generosity and tremendous efforts of its members and is grateful for their willingness to serve,
Therefore be it resolved that the Society for the Study of Amphibians and Reptiles offers its gratitude and sincere thanks for jobs well done to the following individuals: Lee Fitzgerald, Board of

Pat Gregory, Dave Cundall, and Julian Lee at the Annual Picnic. Photo by Marion Preest.

Directors; Linda Ford, Board of Directors; Robert Powell, Editor, *CAAR*; Hinrich Kaiser, Section Editor (Anura), *CAAR*; Gordon Schuett, Section Editor (Natural History Notes, Snakes), *Herpetological Review*; Omar Torres-Carvajal (Current Research Section Editor), *Herpetological Review*; Sharon Downes, Associate Editor, *Journal of Herpetology*; P. Stephen Corn, Series Editor, *Herpetological Conservation*; Dennis Desmond, SSAR Webmaster; Dawn Wilson, Resolutions Committee Chair.

Joint Resolution on the Sam Noble Oklahoma Museum of Natural History:

Whereas, the ichthyologists and herpetologists appreciate the warm welcome extended by the Sam Noble Oklahoma Museum of Natural History and its director Ellen Censky, and, Whereas, the state-of-the-art Integrated Pest Management kept us confined to the lobby, we suspect based on some members' reputation for their eating and drinking habits, and, Whereas, the state-of-the-art Security kept the collection tours to a controllable number, we suspect based on some members' reputation for running amok, and,

Whereas, we truly enjoyed the wonders of Brazil through the photo exhibit and the eye-to-eye view of the *Apadosaurus* via the "dinovator,"

Therefore be it resolved that the societies wish to express our sincere gratitude and appreciation for the wonderful times we have had at the Oklahoma Museum of Natural History.

Joint Resolution about the Kansas State University conference planners:

Whereas, ichthyologists and herpetologists have changed the way they organize and operate annual meetings, and,

Whereas, the professional leadership, expertise, congeniality, watchful eyes and unflagging sense of humor provided by our conference planners is key to our success, and,

Whereas, we are now able to offer ichthyologists and herpetologists a well planned and organized meeting,

Therefore be it resolved that we extend our heartfelt thanks and gratitude to Sharon Brookshire, Jan Hudzucki, and their associates at Kansas State University Division of Continuing Education.

Joint Resolution on our Hosts:

Whereas, the University of Oklahoma hosted the joint meetings of the American Society of Ichthyologists and Herpetologists, Society for the Study of Amphibians and Reptiles, Herpetologists' League and American Elasmobranch Society (a.k.a. Jimmy) at the United States Postal Service National Center for Employee Development and Marriott Conference Center in Norman, Oklahoma, and,

Whereas, two social events, including this memorable banquet, were also held at the Sam Noble Oklahoma Museum of Natural History, and,

Whereas, the efforts of the Local Committee and sponsoring institutions have made this a marvelous, if slightly claustrophobic, meeting and,

Whereas, the meeting breaks were provided with soft drinks and coffee to our heart's content, even though there were no goodies to go along with it but that's okay because,

Whereas, popcorn *ad libitum* was freely available in the dining hall and lounge, and,

Whereas, excellent papers and posters were presented concerning the study of amphibians, reptiles and fishes, both bony and cartilaginous, and

Whereas, an atmosphere fostering scientific advancement and camaraderie among old and new friends was created and maintained,

Therefore be it resolved that the societies thank the Sam Noble Oklahoma Museum of Natural History and the Department of Zoology of the University of Oklahoma for sponsoring the meeting, and,

Be it further and most decidedly resolved that we express our sincerest gratitude to the Local Committee chaired by Janalee Caldwell and consisting also of Charles Carpenter, Vic Hutchison, Edith Marsh-Matthews, William Matthews, Laurie Vitt, Ellen Censky, Richard Broughton, Sara Cartwright, Amy Estep, and a host of University of Oklahoma students in ichthyology and herpetology.

David Green, ASIH Resolutions Chair, also read some interesting resolutions regarding the weather, the "pleasure shuttles" to WalMart, the spelling of "ichthyology," and the pronunciation of JMIH. Meeting attendees appeared particularly appreciative of the Local Committee arranging opening of the bar at the NCED 4 hours earlier than normal every day. The Banquet closed with

Linda Ford and Dave Hillis enjoying the music of "Harvey and the Wallbangers" after the SSAR Bar-B-Q. Photo by Marion Preest.

Ernie Liner and Norm Scott compare tee shirts during the Annual Picnic. Photo by Erik Wild.

thanks to the Local Committee and Conference Organizers and an enthusiastic invitation from Henry Mushinsky to attend to 2005 Joint Meeting in Tampa, Florida (6–11 July).

Board Meeting and Business Meeting Summaries

Society President Janalee Caldwell called the Annual SSAR Board Meeting to order at 0800 hrs on 26 May 2004 at the NCED/Marriott Conference Center in Norman, Oklahoma. In attendance were 10 members of the Board of Directors and 9 Editors, Committee Chairs, or members of the Society.

Minutes of the 2003 Board of Directors Meeting were approved. President Caldwell presented summaries of reports made by SSAR Officers, Editors, Committee Chairs, and Coordinators. President Caldwell reported that sites for the joint meeting have been finalized for the next four years (2005 in Tampa, Florida; 2006 in New Orleans, Louisiana; 2007 in Ithaca, New York; and 2008 in Montréal, Canada). The 2008 meeting will be held in conjunction with the 6th World Congress of Herpetology (WCH). David Green (Member, WCH Local Planning Committee) made a number of comments about the location of the meeting, accommodation, and amenities available. A letter of invitation was received from Patrick Gregory (President, ASIH) to hold the 2009 Joint Annual Meeting in Vancouver, British Columbia. Approval was received from the Board to accept this invitation. Henry Mushinsky indicated that, rather than simply accepting invitations, an attempt was being made to distribute meetings around the U.S. Aaron Bauer (Member, 5th WCH Local Planning Committee) presented information on the 5th WCH to be held in Stellenbosch, South Africa (20–24 June 2005). Information about the meeting can be found on the website of the Herpetological Association of Africa (http://www.wits.ac.za/haa).

President Caldwell proposed and received approval from the Board (by email) to form a Web Oversight Committee. This committee would examine the Society website regularly, review new material submitted for posting to the site, and suggest material to be added to the site. A document describing the duties of Committee Chairs and Coordinators was rewritten and posted to the SSAR website. Committee Chairs are now responsible for updating relevant material on the website. A description of SSAR and the *Journal of Herpetology* was written to be included in the 2004 Buyer's Guide for Allen Press.

New appointments made by President Caldwell during the past year include Kirsten Nicholson as Chair of the Nominations Committee, Stephen Richter as Chair of the Conservation Committee, and Richard Durtsche as Symposium Coordinator. President Caldwell noted that SSAR was referred to as "the largest international herpetological conservation society" in the ESA publication *Frontiers in Ecology and the Environment* 2:164 (2004).

Letters of congratulation were sent to the six winners of the 2003 Grants-in-Herpetology Awards and to the winner of the 2003 Dean Metter Memorial Award. Letters of thanks were sent to Drs. Richard Vogt and Ning Labbish Chao for their organization of the 2003 Joint Meeting in Brazil, to Dr. Joseph R. Bidwell and colleagues for their contributions to the SSAR Grants-in-Herpetology program in memory of Dr. James N. Dumont, and to Dr. Toad of Toad Hollow Winery for a donation made to the SSAR live auction. Following tradition, President Caldwell has contributed to the President's Challenge Fund.

Theodora Pinou (Treasurer) reported that the Society made a profit of \$64,438 for calendar year 2003 (\$8,026 in operating income, \$43,826 in donations, and \$12,586 of realized investment income). All investment funds experienced positive returns in 2003. As a result the unrealized loss of \$75,404 in 2002 has been

Eager bidders, Brad Moon, Ali Rabatsky, and Meredith Mahoney, at the SSAR/HL Auction. Photo by Marion Preest.

reduced to $34,597. As this is still just a "paper" loss it will only be realized if assets are sold. Dora made a number of suggestions regarding society funds. She suggested employing a professional portfolio manager to provide advice (but without having trading capacity) on investments. The Board approved President Caldwell's suggestion that a financial advisory committee be formed.

The decline in membership numbers noted in last year's report continues this year. It can be attributed partly to late membership renewals; however, some of the decline might be due to the launch of BioOne and the online availability of Society publications. Dora recommended transferring the duties of the Membership Office to the Treasurer's Office after our contract with Schmidt and Associates ends in December, 2004. She suggested that this change will permit a more focused management of finances, reduce annual service charges, and ensure follow up on returned deposit checks, etc. President Caldwell reminded Board members that the decision to split the duties of the Treasurer's and Membership Offices was made quite recently when Bob Aldridge was Treasurer in order to reduce the amount of work involved as Treasurer. A number of officers expressed satisfaction in their dealings with the current Membership Office. The Board approved non-renewal of the contract with Schmidt and Associates and consolidation of the Membership and Treasurer's Offices.

Breck Bartholomew (Publications Secretary) reported that income from sales of the Society's publications totaled $35,516. Sales were down somewhat compared with recent years, likely reflecting the economy, lack of advertising, and the fact that there were no sales of SSAR publications at the 2003 meeting in Brazil (this will also happen at the two upcoming meetings in Canada in 2008 and 2009).

A reduction in the overrun of journals (from 500 to 250 copies) will help reduce accumulation of inventory. Breck proposed that journal issues be kept for 5 years. After this time, excess journals should be brought to annual meetings and heavily discounted or given away.

Breck made a number of proposals to deal with the bulk of the SSAR inventory currently located in St. Louis (2,100 sq. ft.). Some of this material will be transported to Salt Lake City. However, because of significant transportation and storage costs, a reduction in the volume of material to be sent to Utah is desirable. Breck proposed a "firesale" on much of the inventory. He will send announcements to museums, libraries, collections facilities, and international herpetological societies. He will also notify SSAR members regarding publications that are about to go out of print. Rafael de Sá will work with Aaron Bauer and Breck and contact WCH organizers to locate international scientists and institutions that may be interested in purchasing copies of SSAR publications (especially journals).

Breck proposed taking a number of older *Herpetological Circulars* out of print. He suggested an initial sale on these items followed by distribution/sale at annual meetings. Several *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* circulars may be recycled to avoid adding to confusion over names. Sales on a number of books in the *Contributions to Herpetology* series have dropped to a point where Breck suggests making them available at reduced prices to members, regional societies, and book dealers. Sales of a number of

Steven Whitfield, Corinne Richards, Melissa Pilgrim, and Mizuki Takahashi. Four of the five recipients of the 2004 Grants in Herpetology Awards made at the Annual Business Meeting (Franklin Enrique Castañeda Menéndez not present). Photo by Eric Wild.

Facsimile Reprints in Herpetology have slowed and these issues could be taken out of print and liquidated. There was some discussion of the future of *Catalogue of Amphibians and Reptiles (CAAR)*. Given that many members may not be familiar with *CAAR*, the Board approved a suggestion that a copy of *CAAR* be sent to all members. The Board gave general approval for Breck to implement the above proposals.

Archiving of SSAR publications and Society records was discussed. The Society would need to identify someone able to determine what material is archiveable and also locate a suitable site.

Breck proposed implementing a fee of $10 for all late membership renewals. This will cover the extra costs of packaging and postage. Concern was expressed that a fee may cause some members to not renew their membership. An explanation of this fee will be made in the membership renewal notices. This proposal was approved by the Board.

Robert Powell, Editor of *CAAR*, reported on the status of this publication effort. He thanked Hinrich Kaiser for his service as Section Editor for Anura. Bob noted that the 2003 contributions to *CAAR* consisted of 20 accounts (Nos. 761–780; 3 salamander, 4 frog, 2 turtle, 3 lizard, and 8 snake accounts) for a total of 103 printed pages. Color plates were included in 16 of the accounts. The 2004 subscription is scheduled for publication on June 30 (20 accounts) and Bob has tentative plans for another 20 accounts for 2005. Bob requested a slight increase in the budget for 2005 to allow for typical page costs (including continued use of color plates) and acquisition of software upgrades. From 2004, printing of *CAAR* will occur in Salt Lake City, thus obviating the need for shipping archived copies to the Publications Secretary. A number of personnel changes are anticipated. Bob plans to resign in 2004, Andy Price will serve as Editor and continue as Section Editor for lizards, and Gregory Watkins-Colwell (Index Editor) will become Associate Editor.

Kraig Adler (Editor) reported on the publication activities of *Contributions to Herpetology*. A recent publication in this series

was "*Islands and the Sea: Herpetological Explorations in the West Indies*" edited by Robert Henderson and Robert Powell. "*Field Guide to Amphibians and Reptiles of the West Indies*," by S. Blair Hedges is expected in July of 2004 and although most manuscripts have not yet been received, formatting has begun on "*Biology of the Reptilia*, Volume 20 (Morphology)," edited by Carl Gans and Abbot Gaunt. Beyond next year, publications will include "*Herpetological Time Travel Through the Zoo and Aquarium World*," by James B. Murphy, "*Tasks and Problems Studying the Life of Reptiles in Zoos*," by Hans-Günter Petzold, and "*Lizards of Southern Africa*," edited by William R. Branch and Aaron Bauer.

Editor of *Facsimile Reprints in Herpetology*, Aaron Bauer, reported that publication of "*Les Tortues de l'Indochine*," by René Bourret has been delayed because of new Vietnamese copyright laws. "*The Herpetological Contributions of Mario Giancinto Peracca*," edited by Franco Andreone and Elena Gavetti (with an English translation of the introduction) will be published in late-mid 2005. "*The Shorter Herpetological Contributions of Andrew Smith*" will be released in conjunction with the 5th WCH in Stellenbosch, South Africa. "*The Herpetological Contributions of John Edward Gray*" is anticipated beyond 2004. A number of other titles are under consideration for the future.

Herpetological Circulars Editor, John Moriarty, reported that HC 33, "*Johann von Fischer and His Chameleons: The History of the Common Chameleon*" is planned for early 2005. A grant from the Smithsonian Institution has been requested to cover printing costs. "*A Review of Marking Techniques for Amphibians and Reptiles*" is anticipated in late 2005. Robin Jung and Joe Mitchell, Co-Editors of *Herpetological Conservation* reported that Volume 2 in this series, "*Ecology, Conservation, and Status of Reptiles in Canada*," is expected in summer, 2004. They provided a detailed summary of plans for Volume 3 "*Urban Herpetology: Ecology, Conservation and Management of Amphibians and Reptiles in Urban and Suburban Environments*" including a mission statement, a long list of potential chapters and authors (some of whom have already agreed to contribute), and a tentative timetable. Further information about Volume 3 is available on the SSAR website. Robert Hansen (Editor) reported a 21% increase in the number of pages in *Herpetological Review* Volume 34 compared with Volume 33. He expects Volume 35 to be approximately the same size as Volume 34. This increase in page numbers has not entailed an increase in costs because the production of *Herpetological Review* is now completely electronic. A special effort was made to deal with a backlog of natural history notes (rate of publication increased by nearly two-fold). Rate of rejection of manuscripts has increased over recent years as competition for page space in *Herpetological Review* has become more intense. A number of authors have been referred to the new SSAR author assistance program and an increasing number of manuscripts are being submitted and handled electronically with an associated decrease in labor and costs. Brian Bowen (Associate Editor) has requested that he be replaced. Gordon Schuett (Section Editor for Natural History Notes) was replaced by Andrew Holycross, Omar Torres-Carvajal was replaced by María del Rosario Castañeda, and David McLeod was added as Copy Editor.

Journal of Herpetology Editor, Brian K. Sullivan, submitted a report indicating that the number of submissions in 2003 was similar to that in 2002. The acceptance rate in 2003 was comparable with that in recent years (50–60%). The postacceptance time lag has been reduced and is now 3–4 months. A preacceptance time lag still exists, although this has been addressed partly by the appointment of new Associate Editors and increased electronic submission of manuscripts. Sharon Downes was replaced by David Holzman as an Associate Editor. Brian continues to search for new Associate Editors.

Reports were received from Chairs of the following standing committees and Coordinators: Conservation Committee, Dean Metter Memorial Committee, Henri Seibert Awards Committee, Kennedy Student Award Committee, Meeting Planning Committee, Nominations Committee, Resolutions Committee, Standard English and Scientific Names Committee, and Student Travel Awards Committee, Elector, Symposium Coordinator, and SSAR Representative to AIBS.

Stephen Richter (Conservation Committee) reported that a new committee composed of 10 individuals was formed. This committee has updated the conservation material on the SSAR website and provided new links from this site. A tentative list of initiatives for the coming year includes development of a pamphlet describing the role of humans in the spread of amphibian diseases, updating state conservation links, and developing associations with other conservation organizations.

Chair of the Dean Metter Memorial Award Committee, Joseph Beatty, reported that the screening committee received four proposals this past year. An award was made to Dean Croshaw for his proposal "Evaluating the fitness consequences of polyandry in marbled salamanders." In 2004, proposals are being accepted through 15 July and the committee hopes to make two awards by 15 August. Beginning in 2005, all proposals must be post-marked by 28 February (with SSAR dues being paid by the end of the previous December).

Marion Preest reported that five Henri Seibert Student Awards were made at the 2002 Kansas City meeting. This past year the (recently very large) Ecology/Evolution Category was split in two. The Board discussed retaining five categories (Ecology, Evolution, Conservation, Systematics, and Morphology/Physiology). Given the usually low numbers of participants in the Systematics category, a motion was made and approved by the Board to combine the Systematics and Evolution categories. This change will be implemented in 2005. Bob Gatten reported that the winner of the 2004 Kennedy Student Award is Cynthia P. de A. Prado for her paper:

Prado, C.P. de A. and C.F.B. Haddad. 2003. Testes size in leptodactlylid frogs and occurrence of multiplemale spawning in the genus *Leptodactlyus* in Brazil. *Journal of Herpetology* 37(2):354–362.

Henry Mushinsky (Chair, Meeting Planning Committee) reported on the development of plans for the 2005 JMIH meeting in Tampa. A meeting will be held in Norman with representatives from SSAR, HL, and ASIH to continue the discussion of sharing the costs/profits of the joint meetings. A comment was made that the joint meetings are now sufficiently large that professional conference organizers are essential for the smooth running of these meetings.

Kirsten Nicholson (Chair, Nominations Committee) noted that four new Directors (three regular member and one non-US member, class of 2008) and a President-Elect are needed this year. Rafe

Brown, Brad Hollingsworth, Meredith Mahoney, Jim McGuire, Greg Pregill, and Tod Reeder have agreed to run for regular Board member positions and Oscar Flores-Villela and Rick Shine have agreed to run for the non-US Board member position. Roy McDiarmid and Joe Mendelson, III will run for the President-Elect position. A secretary and treasurer also need to be elected. Dora Pinou (current Treasurer) and Marion Preest (current Secretary) are willing to run for reelection.

Resolutions were read by Dawn Wilson at the 2003 meeting in Manaus thanking retiring members of SSAR for their service and acknowledging Walter Hödl for his presentation of the SSAR President's Travelogue. Linda Ford has replaced Dawn Wilson as Chair of the Resolutions Committee. Brian Crother reported that an update of the Standard English and Scientific Names List was published in *Herpetological Review* 34:196-203. Although successful in standardizing usage of most names, the list has also generated some controversy. The committee will begin work on a new volume in late 2004 and publication is expected in 2007. Brian commended the members of the committee for their service. Twenty-two applications were received for the Student Travel Award and ten awards were presented by Dawn Wilson at the Annual Banquet in Manaus.

Maureen Kearney (Elector) reported the election of two Board members, class of 2006 (David Hardy—Regional Society Representative and Richard Wassersug—Regular Member) in Fall, 2003. In his report, Ruston Hartdegen presented the mission statement, general goals, and goals for 2003 for the Relations with Herpetologists at Zoological Parks Committee. Specific goals for 2004 include the distribution of a survey to explore the willingness of some North American zoological organizations to work with outside researchers, the development of a website linked to the SSAR site, the development of a database of papers on zoo/academic collaborations, and discussion of a symposium on Zoo Research to be held at an annual meeting.

Al Savitzky submitted a thorough report detailing his activities as representative to the American Institute of Biological Sciences (AIBS). He attended the 2004 AIBS and BioOne annual meetings. A number of issues discussed at the AIBS meeting were of concern to SSAR. The Public Policy Office of AIBS continues to expand, and congressional action by the society remains a major initiative. Concern was expressed about stagnant funding levels from federal agencies and the proposal to move science education from NSF to the Department of Education. Representatives of member societies and organizations were given time to provide input into the future direction of AIBS, particularly regarding services and actions.

The BioOne meeting and teleconference gave publishers and librarians an opportunity to discuss concerns about future policies of BioOne, the status of legacy journals, the impact of electronic publishing on not-for-profit publishers, and the current status of BioOne. The Assistant Dean of Libraries of the University of Kansas described studies detailing an overwhelming preference by faculty and students for direct delivery of electronic copy. As a consequence, libraries are being redesigned as places for electronic access to journals and sites for study groups rather than locations where paper copies can be obtained. In a recent survey, 75% of libraries at major research universities report that they are prepared to stop subscribing to journals to which they have electronic access. Information was provided in the report on online delivery of legacy journals and "open access" or free delivery of online information. All societies, including SSAR, must consider the consequences to societies of the shift from print-primary to electronic-primary publication. It was agreed that BioOne must provide sustained and substantial income to society publishers, rather than supplementary income.

Dick Durtsche provided a comprehensive report on his activities as Symposium Coordinator. He received a proposal from Robert Henderson (Robert Powell and Gordon Schuett, co-organizers) for SSAR to sponsor "The Biology, of Boas, Pythons, and Related Taxa" at the 2005 Annual Meeting in Tampa. A motion to accept this proposal was made and approved by Board members. The Board supports the recommendation that symposia be restricted to morning and afternoon sessions and stressed the importance of setting aside time for group discussions during and after symposia to distinguish them from regular paper sessions. The Board asked for acknowledgement of SSAR in any publications resulting from symposia sponsored by the society.

Kraig Adler and Breck Bartholomew provided a report on the sales (by auction) of the Sherman A. Minton and Robert E. Gordon libraries. The proceeds from these sales will go to into "The Sherman A. Minton, M.D., Endowment" and "The Robert E. Gordon Endowment" and interest used to support student travel to SSAR meetings and book-length publications by SSAR respectively. Totals of $13,456 (Minton Endowment) and $22,505 (Gordon Endowment) were raised.

Some time was spent discussing annual elections. No election will be held in 2005 and biennial elections will commence in 2006. A member of the Society recently expressed concern over the lack of confidentiality of ballots. A possible solution would be to include envelopes with the ballot. This, however, would increase costs substantially. The Secretary and Nominations Committee Chair will devise a mechanical solution to the lack of confidentiality (e.g. provide a tear-off portion with name of sender). Ballots will be sent to international members in July/August this year to ensure their receipt well before the election deadline.

The Board discussed the formation of an Education Committee proposed by President Caldwell to, for example, handle requests from the public on information about herpetology, provide mentors to those interested in careers in herpetology, establish connections with regional and national science fairs, and interact with the AIBS Education Committee. Suggestions were made that SSAR form a joint Education Committee with The Herpetologists' League and that this Committee establish ties with regional herpetological societies. The Board approved the formation of an Education Committee to exist independently or with the involvement of The Herpetologists' League.

The formation of a Web Oversight Committee (WOC) received Board approval via an email ballot earlier this year. There was some discussion of the proposed composition and duties of this committee.

The Board discussed the issue of providing members with access to SSAR journals via a relatively new program in BioOne. Discussion ensued about why members should support a Society if access to hard copies of journals is no longer available. Suggestions ranged from participating in annual meetings, access to various awards, discounts on society publications, involvement in po-

President Janalee Caldwell passes the SSAR gavel to President-Elect Robin Andrews at the Business Meeting. Photo by Erik Wild.

litical issues and outreach programs, to support of conservation concerns. Board members were charged with continuing to think about these issues.

A report was received from the Chair of the Grants-in-Herpetology Committee (Erik Wild) after the Board Meeting. Fifty proposals were received in 2004 and awards were made in each of five categories (Conservation, Field Research, Laboratory Research, Travel, International). No applications were received in the Herpetological Education and Bibliographic Research categories. Erik expressed satisfaction in changes implemented last year in the application process, particularly electronic submission of proposals, and thanked the members of the Committee.

The Board approved the SSAR 2005 budget. There being no further business President Caldwell adjourned the meeting at 1545 hrs.

The Annual SSAR Business Meeting was called to order by President Caldwell at 1703 hrs on 29 May. Approximately 75 SSAR members were in attendance. President Caldwell summarized a number of reports presented at the Annual Board Meeting by Officers, Editors, and Committee Chairs. There was discussion of the venues of upcoming meetings. David Green extended an invitation to attend the 2008 Joint Annual Meeting in Montréal, Canada and Aaron Bauer encouraged attendance at the 5th WCH in Stellenbosch in June, 2005.

Plans for the Web Oversight and Education Committees were described and there was brief discussion of the roles of these committees. Members, especially graduate students, are encouraged to volunteer for SSAR committees. The LINNE Initiative (Legacy Infrastructure Network for Natural Environments), a project to increase federal funding for promoting systematics and biological collections and linking biological collections, research facilities, and experts with the goal of making biological diversity information easily accessible, was discussed and information pamphlets were distributed to those present.

Kirsten Nicholson presented the slate of nominees for the 2004 annual election. President Caldwell asked for the names of additional nominees; however, none was received. Marion Preest announced the winners of the 2004 Dean Metter Memorial Award, the Kennedy Award, and the Henri Seibert Student Awards. The Grants-in-Herpetology Awards were presented by Erik Wild. President Caldwell then passed the SSAR gavel to President-Elect Robin Andrews and the meeting was adjourned at 1747 hrs.

— Respectfully submitted by
Marion Preest, SSAR Secretary

NEWSNOTES

Slowinski Award Announced for 2004

The Center for North American Herpetology is pleased to announce that the recipient of The Joseph B. Slowinski Award for Excellence in Snake Systematics for 2004 is Simon Creer, a researcher in the School of Biological Sciences at the University of Wales, Bangor, Gwynedd, United Kingdom.

On September 12th 2001, the world lost one of its premier biologists, a loss that went virtually unnoticed in the wake of the tragedy that befell the United States the previous day. Joseph Bruno Slowinski, the 39-year old curator of amphibians, turtles, reptiles, and crocodilians at the California Academy of Sciences in San Francisco, died in the jungles of Burma from the bite of a venomous snake. Joe was bitten on September 11th and, despite heroic efforts to save his life by expedition companions and colleagues, succumbed to the effects of the bite the next day. Eventually, the world took notice, and numerous media outlets across the nation and throughout the world chronicled Joe Slowinski's exemplary career, cut so tragically short.

A distinguished committee, comprised of Frank Burbrink (City University of New York, Staten Island), Brian Crother (committee chair, Southeastern Louisiana University, Hammond), and Robin Lawson (California Academy of Sciences, San Francisco), have deemed the paper entitled "Assessing the Phylogenetic Utility of Four Mitochondrial Genes and a Nuclear Intron in the Asian Pit Viper Genus *Trimeresurus*: Separate, Simultaneous, and Conditional Data Combination Analyses," (2003. Molecular Biology and Evolution 20[8]) , as the most distinguished paper on snake systematics to appear worldwide during 2003. The paper was co-authored by Anita Malhotra and Roger S. Thorpe (all of the University of Wales).

As senior author of the paper, Simon Creer becomes the second recipient of The Slowinski Award, and will receive a check from The Center for North American Herpetology for US $500 along with a commemorative memento in recognition of his achievement.

LACM Herpetology is Open

As many of you know, in June of 2003 the herpetology staff of the Natural History Museum of Los Angeles County (LACM) were laid off due to a budgetary shortfall. Since then, the section of Herpetology has been overseen by Ichthyology staff comprising Dr. Christine Thacker (curator), and Jeff Seigel and Rick Feeney (collection managers). Many herpetologists have asked about the status and activities of the Herpetology section and, in particular,

whether Herpetology is still open for business and what care is being taken of the excellent collection of nearly 180,000 specimens of amphibians and reptiles. We in Ichthyology want to assure the herpetological community that we are committed to the preservation and maintenance of our herpetology collection, and that the collection is open for your use. We are continuing to process loans and data requests, and provide access and assistance for visitors wishing to examine specimens. The collection is housed in compactors in a secure, climate-controlled facility, and the storage conditions are excellent. We remain hopeful that Herpetology staff positions will be restored at some time in the future; until that happens, we encourage those seeking to use the collection to contact one of us at (213) 763-3374, or to e-mail us at the addresses given on our website: http://www.nhm.org/research/fishes/index.html.

LizardChasers.Org

LizardChasers.org is a new web site which offers opportunities for students, interns, and volunteers interested in herpetology. Some research projects are carried out in the southwestern U.S. desert. Topics of study include conservation, behavioral, and evolutionary ecology. Several opportunities for the summer of 2005 will include fire ecology of the Bunch Grass Lizard (*Sceloporus slevini*) in southeastern Arizona. Photo galleries of herps and study sites throughout the southwest U.S. are also on display on the site: http://www.lizardchasers.org. For additional information, contact Paul Hamilton (e-mail: info@lizardchasers.org or phamilton@asu.edu), Arizona State University, West Campus, Department of Integrated Natural Sciences, PO Box 37100, Phoenix, Arizona 85069-7100, USA.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

16–18 January 2005—Biology of the Rattlesnakes conference, Loma Linda, California, USA. Information: www.BiologyoftheRattlesnakes.org.

19–24 June 2005—Fifth World Congress of Herpetology, Stellenbosch University Campus, Stellenbosch, South Africa. Information: http://www.wits.ac.za/haa/5wch.htm.

6–11 July 2005—48th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists. University of South Florida, Tampa (USA). Information: http://www.dce.ksu.edu/jointmeeting/.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **María del Rosario Castañeda**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Perch Height and Habitat Preference in Anoles of Grenada

Two species of anoles coexist in Grenada (Lesser Antilles): *Anolis richardii* and *A. aeneus*. The authors tested the previously proposed hypotheses that (1) *A. richardii* is more abundant in densely shaded areas, and (2) adult males of *A. richardii* perch higher than smaller conspecifics and *A. aeneus* of all age classes. Also, they studied the structural niche breadth and degree of niche overlap between the two species based on perch height and diameter, lizard orientation, and degree of insolation. Four different habitats were considered: mangrove forest (dominated by *Rhizophora mangle*), dry scrubland (dominated by *Acacia nilotica*), dry woodland (recently cleared), and streamside broadleaf forest (mixed agriculture). Results agreed with previous hypotheses in that higher densities of *A. richardii* were found in more densely shaded areas whereas higher densities of *A. aeneus* were found in more open, sunny areas. However, differences in perch height were found among the habitats, with *A. aeneus* perching higher that *A. richardii* in the streamside forest. The structural niche breadth analysis classified both species as habitat generalists, and the niche overlap values indicated syntopy in some habitats. This study highlights the effect of environmental characteristics on habitat utilization by anoles.

Harris, B. R., D. T. Yorks, C. A. Bohnert, J. S. Parmerlee, Jr., and R. Powell. 2004. Population densities and structural habitats in lowland populations of *Anolis* lizards on Grenada. Caribbean Journal of Science 40:31–40.

Circadian Cycles, Environmental Conditions and Daily Activity Patterns of Whiptail Lizards

Circadian clocks and environmental conditions seem to be the main factors influencing animal activity patterns. Field studies on reptiles suggest that environmental temperature is the main determinant of initiation and cessation of activity; however, environmental stimuli can also obscure endogenous rhythms. The authors

tested the effect of soil temperature, hunger, rates of water evaporation and endogenous rhythms in the early cessation of activity in *Aspidoscelis gularis* and *A. inornata*. Lizards were kept in activity chambers with a stable temperature gradient and a permanent source of water. Different trials to test the effects of feeding on activity were performed on normal and reversed photoperiod regimes. No relationship between high temperatures and cessation of activity was found, although a critical soil temperature was required for initiation of activity. In addition, no effect of food and water availability was found on activity patterns. The results support the primary role played by circadian cycles in the initiation and cessation of activity, and the persistence of the cycle in the absence of limiting environmental factors.

WINNE, C. T., AND M. B. KECK. 2004. Daily activity patterns of whiptail lizards (Squamata: Teiidae: *Aspidoscelis*): a proximate response to environmental conditions or an endogenous rhythm? Functional Ecology 18:314–321.

Temporal Partitioning of Calling Activity in Amphibians

Most species of amphibians in the tropical region of South America breed only during the rainy season. This strict timing might lead to temporal and spatial competition for oviposition and calling sites. The authors studied the temporal partitioning of calling activity and its correlation with rainfall, temperature, and pond water level in a French Guianan frog community during the rainy season. All 31 species observed, representing different reproductive modes, increased their calling activity with increased rainfall. Explosive breeders, species laying eggs in terrestrial foam nests and on vegetation above water, species with terrestrial oviposition, and species with direct development or with non-feeding larvae showed different calling activity patterns throughout the rainy season. The results support the strong influence of abiotic factors on amphibian reproduction, and the adjustment of calling and reproductive activity according to the requirements of different reproductive modes.

Behavioral Response of *Rana* and *Bufo* Tadpoles to Trematode Parasites

In recent years, there has been an increase in parasite-induced developmental malformations in tadpoles as a result of echinostomatoid infections. Previous hypotheses suggest that this rise could be explained by the increase in host densities because of normal environmental fluctuations and/or changes in the landscape caused by human activity, or by the weakening of the immune system of tadpoles due to pesticides. This study tested an alternate hypothesis, in which the behavioral response to contact with parasites influences trematode infection. Using high-speed video, the authors recorded the response of *Rana silvatica* and *Bufo americanus* tadpoles to larval stages of trematode parasites (cercariae) of the genus *Echinostoma*. Fast starts and sudden changes in position were observed after exposure to the cercariae in both species, though *Bufo* tadpoles exhibited more diverse and violent movements than *Rana* tadpoles. The authors conclude that behavioral response is important for shedding parasites and that factors reducing locomotion in tadpoles, such as the presence of predators or pesticides, increase the risk of parasite infection.

TAYLOR, C. N., K. L. OSEEN, AND R. J. WASSERSUG. 2004. On the behavioural response of *Rana* and *Bufo* tadpoles to echinostomatoid cercariae: implications to synergistic factors influencing trematode infections in anurans. Canadian Journal of Zoology 82:701–706.

Dietary Component of the Fossorial Snake *Atractaspis*

An adult caecilian (*Scolecomorphus kirkii*) was found among the gut contents of a burrowing snake *Atractaspis aterrima*. Natural history information on *Atractaspis* snakes is scarce, especially with regard to their diet, probably as a result of their fossorial lifestyle. Feeding habits of *Atractaspis* are particularly interesting because of their highly modified dentition (teeth mostly reduced with the exception of very long maxillary fangs) and the ambiguous phylogenetic position of Atractaspidae. The authors report the characteristics of prey and predator (size, size ratio, and position of prey in gut). Also, references and comparisons with previously reported *Atractaspis* gut contents and *Scolecomorphus* predation data are described.

Evolution of Color Variation in *Ctenophorus* Lizards

In theory, animal color patterns represent a compromise between signaling effectiveness and protective crypsis for visually oriented predators. The authors used chromatic (hue) and achromatic (brightness) spectrum measurements and information on predator visual sensitivities to evaluate the role of crypsis in the evolution of color in *Ctenophorus* lizards (*C. decresii, C. fionni,* and *C. vadnappa*). Differences in conspicuousness among populations, between sexes, and between body regions ('exposed' or 'hidden'

from predators), and evidence for local adaptation to different substrates through crypsis were investigated. The authors found differences in crypsis between populations and between sexes, especially in body regions used by males during social and sexual displays. Also, 'exposed' regions were more cryptic than 'hidden' regions in both sexes. These results add evidence supporting the necessary compromise involved in the evolution of color pattern between signaling and cryptic functions.

Ecological and Genetic Components of Behavior in *Desmognathus* Salamanders

Species interactions and dispersal capabilities describe major patterns of community structure, which in turn, has an effect on speciation patterns. The authors studied the influence of species interactions on behavior and population genetics by comparing two populations of *Desmognathus monticola*, one allopatric and the other sympatric with *D. quadramaculatus*. The latter species has more aquatic habits than *D. monticola*, which has been observed to reduce its aquatic habits in the presence of *D. quadramaculatus*. Data regarding behavior (more/less aquatic habits) and individual condition (body mass and length) in allopatric and sympatric settings were recorded in natural environments and laboratory enclosures. Also, sequence data (portion of COI and 12S rRNA genes) were collected. Results indicate that *D. monticola* from areas of overlap with *D. quadramaculatus* have more terrestrial habits than allopatric populations, even in experimental enclosures were *D. quadramaculatus* was excluded. Genetic analyses indicate a recent range expansion of *D. monticola* into areas where it can interact with *D. quadramaculatus*. This paper emphasizes the importance of combining ecology with genetics to study species distributions and behavioral patterns.

Phylogeny of Gymnophthalmid Lizards: Multiple Genes and Model Testing

Recent incorporation of multiple genes to estimate phylogenetic relationships has led to the need for simultaneous modeling of sequence evolution of different genes. The authors evaluated the effects of partitioning among-site rate variation and among-site rate autocorrelation on tree topology and Bayesian posterior probability estimates in a phylogenetic analysis of gymnophthalmid lizards. The data set included sequences of protein-coding nuclear c-mos, mitochondrial ND4, and fragments of the mitochondrial 12S and 16S rRNA genes. Five data partitions were evaluated: (1) all genes combined, (2) protein-coding versus rRNA genes, (3) nuclear versus mitochondrial, (4) nuclear versus ND4 versus rRNA genes, and (5) all individual genes. ModelTest v3.0 was used to determine the best-fit model of evolution for each partition. The General Time Reversible (GTR) substitution rate model was applied to all partitions using Mr. Bayes v2.01, with alternative incorporation of among-site rate autocorrelation (each partition with and without autocorrelated gamma). The three-way gamma partition (c-mos vs. ND4 vs. rRNA) was found to produce significantly higher and less variable posterior probabilities. The resulting phylogenetic hypothesis was used to reevaluate the higher-level taxonomy of Gymnophthalmidae.

Population Structure of *Chrysemys picta* in a Developing Landscape

Fragmentation, habitat loss and disturbance of wetlands affect populations of aquatic turtles. Similarly, disturbance of upland habitats is also detrimental, since these areas are used for nesting and migration between ponds. The authors studied population structure of *Chrysemys picta*, as well as pond and landscape characteristics of 37 ponds distributed along a gradient of urbanization in southeastern New Hampshire. Pond substrate and herbaceous vegetation were negatively associated with turtle abundance, while year of sampling, forest coverage and potential nesting area were positively associated. Higher proportions of males were associated with high forest coverage, high density of roads and high nest predation. Females were found in upland habitats more often than males and showed a higher proportion of injuries related to human encounters. This paper highlights the importance of studies on early stages of turtle declines to recognize population responses to disturbance in human dominated landscapes. The results would allow the identification of early key interventions to prevent local extinction.

ZOO VIEW

". . . In a few years come down and see if anything has happened. A good idea, I believe."—C. B. Perkins, describing in his diary why Galápago Land Iguanas were translocated (*In* Campbell 1978).

In 1932, San Diego Zoo Curator of Reptiles C. B. "Si" Perkins joined a local businessman, G. Allan Hancock, on a trip to the Galápagos Islands to study and collect animals for the Zoo. Hancock's ship was named Valero III, an impressive vessel nearly 200 feet in length and outfitted with the most luxurious trappings; it was perfectly suited for the voyage.

When they reached the islands, Hancock and Perkins decided to move 40 Galápagos Land Iguanas (*Conolophus subcristatus*) from Baltra Island, also known as South Seymour Island, to North Seymour Island which contained no iguanas. On their next trip a year later, they translocated 20 more lizards.

Baltra was an American airbase during World War II in the 1940s. Several thousand military and support personnel were stationed there, in part to guard the Panama Canal. The Baltra lizards disappeared during that period because of habitat destruction, introduction of feral animals, and direct killing by humans.

For 47 years, there appeared to be virtually no successful reproduction or recruitment in the translocated population on North Seymour so a pair of adults was brought to the Charles Darwin Research Center on Santa Cruz Island where they successfully reproduced (Cayot et al. 1994). Populations of feral cats and dogs were reduced on Baltra. In June 1991, 35 five-year-old iguanas were repatriated to Baltra and 24 more were released the next year. This head-starting program was truly an accomplishment deserving praise. If Perkins and Hancock had not intervened years earlier, the land iguana population on Baltra would be extinct.

The situation faced by the Baltra iguanas mirrors the plight of large iguanids throughout the world. Because many species are found on islands, they are particularly vulnerable. For the past several decades, West Indian iguanas of the genera *Cyclura* and *Iguana* have been the focus of many researchers in zoos and aquariums. To underscore this fact, consider the list of authors in the 1982 book *Iguanas of the World*, edited by Gordon Burghardt and A. Stanley Rand; there was not a single one from the zoo and aquarium community! Contrast this with the list of authors in the new 2004 book *Iguanas: Biology and Conservation* edited by Allison Alberts et al.—there are a dozen. In the earlier book, only two iguanines are mentioned in detail in the "Conservation and Management" section—green iguanas (*Iguana*) and banded iguanas (*Brachylophus*). In the new book, Richard D. Hudson and Alberts outline the role of zoos in the conservation of West Indian iguanas (p. 274), a sobering list of 17 taxa requiring attention.

This chapter on the role of zoos was bittersweet reading for me. On the one hand, I am proud of the efforts by my colleagues to save these lizards through genetic research, headstart release programs, training and technology, population recovery and monitoring, and *ex-situ* captive breeding. For the Jamaican Iguana Recovery Program alone, nearly two dozen US institutions provide logistical and financial support. Worldwide, over two dozen institutions support conservation activities on behalf of West Indian iguanas. The sorrow is that these dramatic interventions are needed because so many taxa are at risk.

Alberts, Head of Applied Conservation at the San Diego Zoo, and her coeditors Ronald Carter, William Hayes, and Emília Martins have published a fabulous contribution covering evolution, behavioral ecology, and conservation. One striking feature is that many of the chapters are jointly written by museum, academic, and zoo and aquarium workers, demonstrating increased collaboration. This book will surely stand as the definitive work on this topic for many years to come.

Carl and His Rattlesnakes: Herpetology at the Staten Island Zoo

KEN KAWATA

General Curator, Staten Island Zoo
614 Broadway, Staten Island, New York 10310, USA
e-mail: kawatasiz@aol.com

"The Reptile House was the first large building erected in the Zoological Park," noted Dr. William T. Hornaday, director and general curator of the New York Zoological Park, commonly known as the Bronx Zoo (Hornaday 1918). It is remarkable that this prestigious institution which was opened in 1899 placed an emphasis on reptiles. However, in early days these animals were not considered an important component of a zoo animal collection in this country.

Decades after the opening of the Bronx Zoo, George P. Vierheller, director of Saint Louis Zoo, Missouri, planned a reptile house but members of the zoo control board were concerned about the acceptance of such an exhibit by the public. To convince them, a temporary reptile exhibit was built in a small portion of an old ostrich barn. Soon, several employees were needed for crowd control as a block-long line of visitors waited to view the reptiles (Perkins 1982). After arriving at the Toledo Zoo, Ohio, in 1929, Roger Conant collected reptiles and constructed exhibits in the lobby of an old elephant house, which became instantly popular (Conant 1997). Such a crowd-drawing power may not have been readily recognized. A glance at data from 1930 reveals a relative

scarcity of reptiles and amphibians in American zoos.

Doolittle (1932) listed a total of 61 institutions including three in Canada; of these, eight submitted no statistical data on animals. Eighteen out of the remaining 53 had no reptiles or amphibians, leaving 35 holding institutions. Eleven of them had fewer than 10 reptiles and amphibians. As for mammals and birds, most zoos indicated the numbers of species and specimens by the so-called S-S count, yet only 22 zoos reported the S-S counts on reptiles and amphibians. Others simply noted the number of individual animals in their holdings. Most puzzling is the list from the Philadelphia Zoo, Pennsylvania; 1,268 reptiles and 63 amphibians with no indication of the number of species. In some zoos, exhibits were only seasonal. Typically, snakes were placed in huge numbers in a "snake pit" and most perished before the winter; frogs met a similar fate.

Exceptionally, five zoos in the United States maintained more than 400 specimens in more than 70 species. At the top was the National Zoo in Washington, D.C. with 600 reptiles and amphibians in 150 species followed by Saint Louis Zoo (581 reptiles in 116 species; 86 amphibians and fish), Toledo Zoo (473 reptiles and amphibians in 70 species), San Diego Zoo, California (408 reptiles and amphibians in 107 species), and Bronx Zoo (401 reptiles and amphibians in 84 species). Behind the statistics lay prominent herpetologists who assembled the collections such as Marlin Perkins (Saint Louis), Roger Conant (Toledo), Charles Shaw (San Diego), and Raymond Ditmars (Bronx).

A Small Zoo on an Island

On the list of American zoo herpetologists, another name appears regularly: Carl Kauffeld of the Staten Island Zoo. A close examination of the history of this zoo reveals that the zoo was intimately tied to snakes even before Kauffeld came into the picture (Kawata 2003). In the early 1930s a group of leading naturalists of the community including Harold O'Connell, Carol Stryker and Robert Mathewson, planned a zoo in the eight-acre municipal Barrett Park. They were advocates of snakes and dreamed of a zoo with emphasis on reptiles especially snakes. The zoo was to be built with labor by the Works Progress Administration (WPA), a federal government program created during the Great Depression.

Staten Island is the southernmost and least populated of the five boroughs in New York City (1930 population: 158,346). Yet the small zoo was to become a pioneer in other areas in addition to reptiles. Dr. Patricia O'Connor, the first full-time (most likely the very first) woman zoo veterinarian in the country, worked here (1942–1970), leaving a legacy of many accomplishments. Also, at a time when few zoos emphasized education, it became the prime mission of this institution.

Educational Programs

Even before the zoo opened, aforementioned Stryker and O'Connell conducted programs for civic organizations using snakes, demonstrating force feeding and venom extraction. One day in 1935, Dr. Clifford Pope, a noted herpetologist at the American Museum of Natural History in Manhattan, New York, joined the two men in the venom extraction at the Staten Island Club; "milking," as it was known, was a common practice by zoo herpetologists. In May of 1936 the First International Snake Exposition was held in Grand Central Palace, Manhattan, under the auspices of the Staten Island Zoological Society, the operator of the zoo. Its purpose: To stimulate interest in snakes, and through educational methods, to overcome some of the widespread public fear of them. Ross Allen of Silver Springs, Florida, Frank Buck of the *Bring' Em Back Alive* fame and Raymond Ditmars were among those who attended the event.

Carl Kauffeld, the legendary reptile curator of the Staten Island Zoo, giving a lecture using live snakes at the zoo's auditorium. With colorful theatrics, his presentation marked the annual highlight of the series of natural history talks for members of the Staten Island Zoological Society. Undated photo by Staten Island Zoo.

On 10 June 1936 the zoo opened, consisting of one building in a shape of a large T. Several weeks later Carl Kauffeld, then on the staff of the American Museum of Natural History, arrived as the curator of reptiles. The zoo building had three "wings" for mammals, birds, and reptiles in addition to an aquarium section. The reptile wing, often called the Serpentarium, measures roughly 31 m (104 ft) long and 16 m (54 ft) wide including service areas, with a series of glass-fronted cages and an alligator pool. Highly unusual for any zoo, this new zoo was equipped with a large auditorium, classrooms, and a laboratory.

The staff conducted a variety of educational programs ranging from regularly scheduled lectures for children and young people, high school biology classes, monthly lectures for the Zoological Society members to special lectures on request by various groups, and tours for elementary school children. Within three years after the programs began, more than 15,000 children in elementary school groups visited the zoo; another 600 attended the biology and laboratory classes for high school and college students, and more than 10,000 attended the lectures and club meetings for children and young people. Those programs were conducted primarily by the zoo director, staff veterinarian and the reptile curator (the zoo did not have paid staff for education until the 1970s). The annual highlight of the programs at the auditorium was Carl Kauffeld's lecture on snakes. Throughout their efforts, the staff tried to dispel the popular myths concerning snakes, and to explain interesting facts about them.

"The fear of snakes is not instinctive," Carol Stryker, the first zoo director, noted, adding: "We are interested in obliterating as many of the superstitions concerning snakes as possible." In 1942

Field work was a passion with Carl Kauffeld. For this annual event he often took protégés such as Robert Zappalorti (left, with a Black Racer). In Okeetee, South Carolina, April 1968. Photo by Robert Zappalorti.

the staff inaugurated the "acquaintance program" with the assistance by the members of the Staten Island Herpetological Society. Each Sunday afternoon, some non-venomous snakes were taken out of the cages and handed out from a roped off area for the public to touch. The staff hoped that if the average person could learn to appreciate the snakes they would not kill snakes, and would try to dispel the ignorance and fear of others. "Closely associated with the 'acquaintance program' is the still more fundamental objective of developing a tolerance for snakes which will lead to extensive snake conservation." (Anon. 1942)

Innovative activities by the staff in the pre-WWII period included radio broadcasting of snake venom extraction and a rattlesnake rattle as Stryker held the snake before a microphone. At the zoo, an exhibit was placed in front of a rattlesnake cage with a rattlesnake rattle in a case, attached to a clapper arm of an electric doorbell. As a visitor pressed a push-button at the guardrail the rattle would produce a sound, simulating that of a snake. This prototype was prone to breakdowns due to a relatively crude mechanism. In the late 1950s Kauffeld rehabilitated the device, which was copied by other institutions. This Staten Island original was a forerunner of the participatory and interactive exhibits that blossomed in zoos decades later.

The zoo was a pioneer. Like any pioneers, however, the staff faced challenges. One such example involved television, a rapidly emerging media in 1949. The National Broadcasting Company (NBC) canceled a snake presentation by noted naturalist Ivan T. Sanderson and Carl Kauffeld. This was after an assurance was given that the audience would be warned five minutes prior to the appearance of a live snake. The director of the broadcasting station defended his position stating that some viewers might find a snake disagreeable, particularly during dinner hours. "Apparently NBC wants to force its own prejudice on the public by suppressing an educational show aimed especially at dispelling medieval fears and superstition," Kauffeld commented in response.

Husbandry Highlights

With a group of trained animal care personnel, the zoo established a sound basis for a husbandry program during its infancy. Snakes began to breed; September 1936 saw births of rattlesnakes, including 20 Eastern Diamondback Rattlesnakes (*Crotalus adamanteus*). Captive breeding of any rattlesnake species remained sufficiently unusual in a northern zoo to be worthy of note even in the 1960s. A pair of Canebrake Rattlesnakes (*Crotalus horridus atricaudatus*), collected in the wild in 1956, became the parents of 10 young in 1961. During the same year a captive-bred and reared pair of Indian Cobras (*Naja n. naja*) mated and the female laid a clutch of 10 eggs. However only one hatched, and the hatchling lived a day or so. Multi-generation breeding was still a challenge then. Rattlesnakes continued to reproduce in the following years.

Over the years the zoo accumulated longevity records in captivity. Snider and Bowler (1992) compiled reptilian longevity records in North American collections as of 1990. Records on nine genera of snakes including *Epicrates, Eryx, Pituophis, Rhinocheilus, Spalerosophis, Naja, Agkistrodon, Crotalus* (two species), and *Sistrurus* (two species) were noted at the Staten Island Zoo. Additionally, previously unpublished data were recently found in the zoo's archives which could potentially be longevity records in North America. Of the six Arizona Black Rattlesnakes (*Crotalus viridis cerberus*) born here on 13 September 1967, three were kept at this zoo; the last one died on 3 September 1983, or after 15 years, 11 months, and 20 days. A Great Basin Rattlesnake (*C. v. lutosus*) was received on 1 July 1971 and was euthanized due to anorexia caused by a huge swelling anterior to mid-body on 5 March 1998, or after 26 years, eight months, and four days. Another possible record holder is a male Black Mamba (*Dendroaspis polylepis*) which arrived on 21 October 1970 and died on 19 February 1995, or after 24 years, three months and 28 days.

Conservation and Research

Aside from educational programs to promote reptile conservation, the staff was engaged in various activities. Among the notable was the work in the Pine Barrens region in neighboring New Jersey. Local people routinely harvested snake eggs, primarily of the Pine Snake (*Pituophis melanoleucus*) and also the Corn Snake (*Elaphe guttata*) and the Black Racer (*Coluber constrictor*) for commercial purposes. Some species also became a target by the pet trade. The staff collected eggs, hatched them in the zoo, and returned them into the wild. This release program continued from the 1960s into the 1980s. In later years zoo-hatched corn snakes were released in South Carolina.

Of medical interest, in 1981 malignant fibro-sarcoma was diagnosed, located between the head and left shoulder in a Galapagos Tortoise (*Geochelone elephantopus*); this type of tumor had not been found in a reptile before. Despite advanced treatments she died in 1983. As for more organized research, senior reptile keeper Charles Hackenbrock studied the morphology of the pituitary gland of snake embryos in the late 1950s, utilizing the Corn Snake and the Timber Rattlesnake (*Crotalus horridus*). Embryos were removed at various stages of development; in the case of the rattlesnake they were surgically taken from gravid females. Histological sections of the head were then cut and stained, and the development of the gland was traced from the earliest to the latest stages.

Regarding *in situ* research, in the 1970s Robert Zappalorti, associate curator of herpetology and education, and coworkers conducted a study on the natural history of the Bog Turtle (*Clemmys muhlenbergii*) in southwestern North Carolina. With three-year

grants from various organizations, they broke new ground including the documentation of a previously unknown breeding population of the species.

A Man of Legend

Three decades after his death Kauffeld continues to appear in reptile-related publications and to stir up lively conversations in zoo and herpetological circles. A native of Philadelphia, Carl Frederick Kauffeld (1911–1974) held the title of curator of reptiles beginning in 1936, and the dual title of director and curator of reptiles from 1963 to 1973 at the zoo. He held no college degree. Interestingly, Card and Murphy (2000) reviewed American zoo herpetologists and observed, "Some persons with limited formal education have been some of the most productive zoo professionals." Wemmer (1991) noted, ". . . on the average, herpetologists are more inspired practitioners of their discipline than most bird and mammal curators." He added that their intellectual commitment resulted in a higher publication rate, more collaboration with non-zoo biologists, and more field experience.

Kauffeld typifies this breed. Dr. Wemmer lists 21 scholars in "a gallery of zoo research and zoo biologists" which includes Kauffeld along with well-respected Europeans. Roy Pinney (1984) remarked, "Because of his involvement, no one since Raymond L. Ditmars of the Bronx Zoo and Ross Allen in Florida did more to popularize herpetology by personal contact, by lectures with live snakes, and by writing." Kauffeld authored three books (one of them with C. H. Curran) and more than 200 articles, and enjoyed an international reputation. Also, Kauffeld served as a mentor and helped promote the zoo as a fertile training ground for younger herpetologists.

The name Carl Kauffeld has been inspirational for persons interested in reptiles. Directly influenced by him young employees, volunteers, and ardent zoo fans later became prominent in zoo, medical, and biological fields. A selected list includes (in alphabetical order; in parenthesis are positions held, past or present) Charles Hackenbrock (Chair, Department of Cell Biology, School of Medicine, University of North Carolina), Robert Mathewson (Director, Lermer Marine Laboratory of the American Museum of Natural History), Louis Pistoia (Curator of Reptiles, Columbus Zoo), Manny Rubio (photographer and author), Wade Sherbrooke (Director, Southwestern Research Station of the American Museum of Natural History), Harold Wahlquist (certified fisheries biologist, United States Fish and Wildlife Service), John Werler (Director, Houston Zoo), Robert Zappalorti (President, Herpetological Associates, Inc., New Jersey), and Dave Zucconi (Director, Tulsa Zoo).

Rattlesnakes Making History

"I don't want you to think that we have any idea of trying to compete with other zoos," commented Carol Stryker to a reporter in 1935 regarding the zoo under construction. Snakes represented the highlight, and at the opening of the zoo, rattlesnakes were featured in a simulated desert scene with cacti, sand, and a bovine skull. Taking on this pursuit, Carl Kauffeld "wisely realized that a smaller zoo could not directly compete with larger zoological gardens such as the nearby Bronx Zoo; his solution was to specialize in snakes, especially rattlesnakes" (James Murphy, pers. comm.). "The urge to hunt and collect is strong in most of us, but never stronger in any one group of people than in naturalists—the zoologists and botanists," asserted Kauffeld (1957), and collect he did. By 1964 a total of 42 species and subspecies of rattlesnakes had been exhibited at the zoo, a number exceeded only by the San Diego Zoo.

Of particular importance, the staff attained the major goal in the same year: For the first time in the history of zoos, they harbored all 32 rattlesnake species and subspecies known to occur in the United States. Among other rattlesnake "firsts" were the arrival of a pair of Aruba Island Rattlesnakes (*Crotalus unicolor*) in 1937, the first to be exhibited in the country; a pair of the Arizona Ridge-nosed Rattlesnakes (*C. w. willardi*), the first of their kind to be exhibited in any zoo, in 1941; the Chihuahua Ridge-nosed Rattlesnakes (*C. w. silus*), the first to reach a zoo, in 1961, and the Southwestern Speckled Rattlesnake (*C. mitchelli pyrrhus*) bred in the zoo for the first time in captivity anywhere in 1962.

Most surprising, a rattlesnake from Mexico arriving in January of 1940 turned out to be new to zoology. It was recognized as a new species and given description under the name *Crotalus totonacus*, the Totonacan Rattlesnake, by Dr. Howard K. Gloyd and Kauffeld.

By the late 1960s the scene of the zoo industry had changed. Larger and modern reptile houses were springing up nation-wide, and the animal collection at the Staten Island Zoo was falling behind in terms of sheer numbers of reptile species and specimens. Nevertheless, the rattlesnake collection continued unsurpassed. With 39 species and subspecies the collection reached its all-time high in 1968 (Staten Island Zoological Society 1969). The 1970s proved to be a difficult period for the zoo, beginning with retirement of Dr. Patricia O'Connor, staff veterinarian, and Carl Kauffeld's declining health.

The waning years of Kauffeld also marked the beginning of rapid changes that were to sweep the zoos of the world. Zoos no longer take pride in the size of animal collections or the number of species in particular taxonomic groups. Long gone are the days of collectors, a remarkable and memorable moment in history. Today, this zoo's rattlesnake collection has dwindled to about one-third of its heyday. "However, there is no doubt the Staten Island Zoo will always be identified with Carl Kauffeld and his rattlesnakes" (Gattullo 2001). His legacy represents a tribute to the bygone era of unmistakably unique characters and great collectors, a monument in the global zoo history.

Acknowledgments.—I would like to express my sincere appreciation to the late Dr. Roger Conant, America's senior herpetologist, for providing insightful and informative comments concerning the status of reptiles and amphibians in zoos during early years.

On the Structure of Snake Hemipenes with Comments on their Proper Preparation for Analysis: A Reply to Cadle, Myers, Prudente, and Zaher

HERNDON G. DOWLING
Rendalia Biologists, 1811 Rendalia Motorway
Talladega, Alabama 35160, USA
e-mail: herndondowling@earthlink.net

I was greatly surprised at the lengthy responses (12+ pages) by four authors (Myers and Cadle 2003 [M&C]; Zaher and Prudente 2003 [Z&P] to my brief note (Dowling 2002; 2-pages) on hemipenis preparation and illustration. Both of the response papers emphasized that my note was based upon "entrenched opinions" (M&C) and or "authoritative knowledge instead of a search for answers by empirical observation and test of hypotheses" (Z&P).

Actually, none of the applied terms is correct. The operative term is "prior knowledge." Having prepared more than 400 "fresh" hemipenes in the last half-century, I am well acquainted with the varied difficulties in their preparation—and their appearance when something has gone wrong.

When I began my work on hemipenis morphology as an indicator (AN indicator; not THE indicator!) of snake relationships in 1948, I was testing the opinions and the data of some of the workers on snake relationships who preceded me: Cope (1893, 1895), Ortenburger (1923, 1928), Dunn (1928), Bogert (1940), Malcolm Smith (1943), and others. Also, I did not know where the phyletic value of hemipenes fell as indicators of relationships among the many morphological characters used by various workers. Dunn (1928), for example, after summarizing the classifications of Boulenger and Cope, proposed a simplified system for American snakes, with differences in hemipenes as the primary divisions, vertebrae as the secondary, and the dentary as the tertiary. Bogert (1940) used characters of vertebrae for his primary division of Ethiopian clades, hemipenial morphology as the secondary, and dentition as the tertiary, with his 18 (unnamed) "Groups" not further defined, although indicated by additional morphological description. In contrast, Bourgeois (1969) only used skull characters to distinguish the Ethiopian clades. She also applied subfamilial names to them. She was wrong, unfortunately, in her allocation of members of Bogert's Groups I, III, and IV to Colubrinae, but her identification of Bogert's Group II as Lycophidinae, Group IX as Philothamninae, his Groups XIII and XIV as Boiginae, Group XV as Dispholidinae, Group XVI as Psammophinae, and Group XVII as Aparallactinae have not been greatly modified since that time, and the "Subfamilies" appear to be valid taxa at some level. [The true Colubrinae (*s.s.*) were in Bogert's Group VIII, which she did not examine.]

Malcolm Smith (1943) used skull morphology and dentition as major elements, with supplementary information on head and vertebral morphology, in his familial descriptions of Oriental snakes, with subfamilies identified mainly by scale characters.

It appeared, nevertheless, that dentition, skull morphology, vertebral morphology, and hemipenis morphology all were considered to be prime characters in the identification of snake relationships. I later decided to use them generally in the order of: vertebrae, hemipenis, skull, dentition, and details of scutellation. Biochemical analyses (electrophoresis and immunology) and genomic analyses have more recently been added to the morphological data examined.

SOME CRITICAL REMARKS

First, on the Response by Myers and Cadle

On *Psomophis*.—Apparently hemipenis distortion is in the eye of the beholder. I consider a hemipenis that is bowed over so far that the apex appears to be in the middle of the main lobe (Fig.1) to be "badly distorted." M&C and Z&P apparently think otherwise. A comparison of the original figure (M&C 1994) with their (2003) Fig.1 appear so unlike that they might represent different genera of snakes. These figures also show the advantage of a good drawing over what might have been an excellent photograph. Incidentally, I suspected, as did M&C, that the "bowing-over" of the lobes of the hemipenis was caused by the shrinking of the retractor muscle during preservation, as that I described for *Siphlophis* (Dowling 2002).

M&C complain that I "inexplicably failed to notice that Zaher [1999] had corroborated the general physiognomy of the *Psomophis* hemipenis." This is true, because I saw (and see) little correspondence between the organ as drawn by Edmund Malnate (M&C 1994) [my Fig. 1.] and the photographs published by Zaher (Figs. 74, Upper and Lower)—except in their basal regions—which are also similar to those of, for example, *Saphenophis boursieri* (Zaher's Fig. 76, Upper) and several other genera. It may be noted also that the hemipenis in Zaher's Fig. 74 is tied so far distal to the true base as to obscure the proximal structure of the hemipenis and the point of division of the sulcus.

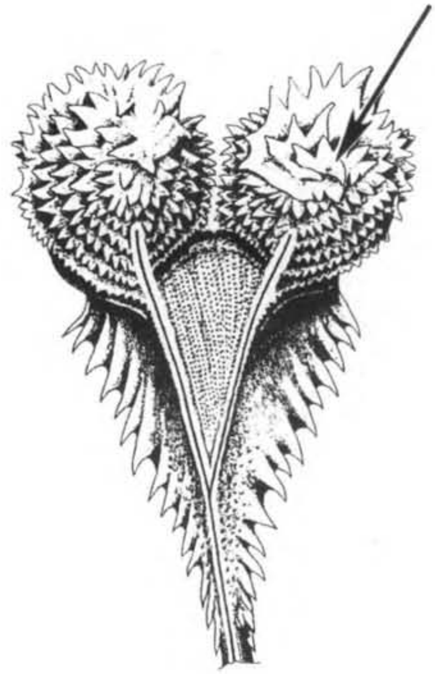

FIG. 1. The hemipenis of *Psomophis genimaculatus* [Xenodontidae; subfamily *incertae sedis*], showing the apex in the center of the apical lobes. [From Myers and Cadle 1994: Fig. 3: pointer added.]

On hemipenis structure and preparation.—M&C complain about "pseudocalyces" that disappear when flattened by "micromanipulation..." which were also found by Z&P. This appears to be a suggestion that none of the responders appreciates that the hemipenis is a double-walled structure, as clearly shown by us, with the aid of Frances Waite's art (see Dowling and Savage (1960: Pl. 1, Fig. 2) [shown here as my Fig. 2.] This is in spite of the quoted "Waite Gibson's" recommendations (M&C 2003: 299), which state in part, "A better specimen is obtained if the needle can be inserted into the lymph sinus and this inflated also."

A hemipenis cannot be merely inflated "like a balloon." As indicated by Ms. Waite, the blood sinus (or the central cavity) of the hemipenis should be filled to fully evert the body of the organ (including the lobes)—and then the outer "lymph sinus" must be filled to fully evert the calyces and flounces. I suggest, therefore, that the disappearing calyces reported by M&C and Z&P are an artifact of incomplete specimen preparation.

M&C have a long discussion (pp. 297–300) on hemipenis preparation, which seems irrelevant in view of the statements of one of Myers' own AMNH postdoctoral fellows, H. Zaher, who writes (Z&P 2003:302): "...hemipenial features are surprisingly variable at all taxonomic levels within colubroids" and "Highly complex transformation series as well as homoplastic occurrences of hemipenial structures at low taxonomic levels do not support the hypothesis of hemipenes being inherently stable morphological complexes...." On this basis, therefore, people are wasting their time in making hemipenis preparations for systematic work. [See my Appendix for another explanation. See also Fig. 3.]

I will comment only briefly on M&C's directions on "Field (Fresh) Eversions." I differ from them in three important respects. 1) I have found that, for a good everted preparation it is necessary to cut the retractor muscles near their connection with the apex of the hemipenis. I first learned this the hard way—by losing the lobes of a *Phyllorhynchus* hemipenis through omitting this procedure. I had injected the hemipenis (both the central cavity and the lymph sinus) with water, tied the base with thread, and cut it off the specimen. It was a good preparation, showing a pair of large apical lobes, and after it had remained in water for 3–4 h, I placed it in formalin, and then, without further observation, asked my current artist to draw it on the following day. To my great surprise and dismay, the finished drawing had no lobes! Placing the hemipenis in formalin, even after several hours, had caused the uncut retractor muscle(s) to shrink and re-invert the lobes (Fig. 4).

Thus, I believe that it is the fixing in formalin that contracts the muscles; the time prior to that is not an important factor. 2) Therefore, the "completely relaxed" hemipenial muscles emphasized by M&C are not important—particularly if they have been previously cut! 3) M&C also suggest that the everted hemipenes "may be left on the snake," which I believe to be in error. Much of Ms. Waite's time at HISS was spent in reconstituting hemipenes that had been pressed flat or ruptured by bottling them with the entire snake, and I have spent considerable time on such work, myself. I emphasize, however, that I have never considered using hemipenes alone in my identifications and determinations of snake relationships, nor would I recommend such a procedure. In a recent paper (Dowling and Pinou 2003), I listed eight morphological characters (one of them hemipenial) that might be used to identify a member of the snake family Xenodermatidae. At various times I have used elements of head scutellation (e.g., Dowling and Price 1988: Fig. 3), mode of dorsal scale reduction (Dowling 1958a), dorsal scale ultrastructure (Dowling and Price 1988: Fig. 4-13), and vertebral morphology (Dowling 1958b, 1988), among others, to aid in the determination of relationships. I have also used data such as chromosome morphology (Cole and Dowling 1970), immunology (Dowling et al. 1983) and

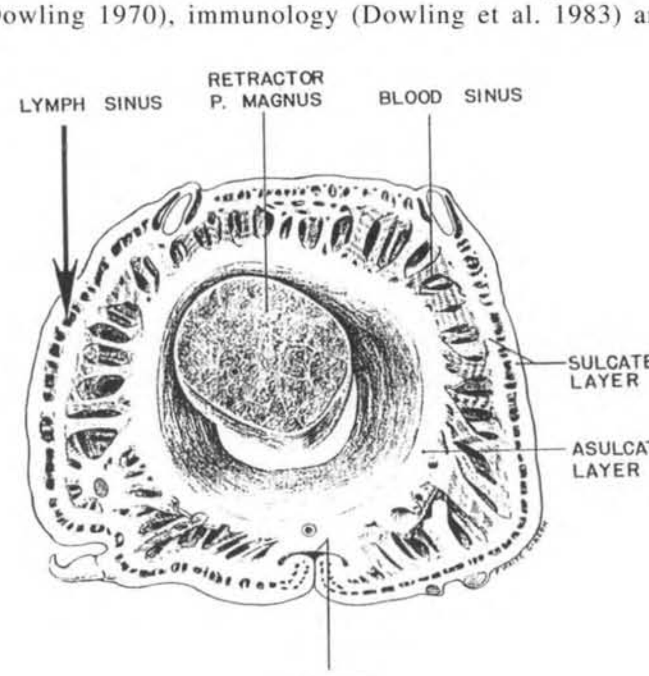

FIG. 2. The cross-section of a hemipenis, showing the two-layered wall; the arrow to the lymph sinus is emphasized. [From Dowling and Savage 1960: Pl. 1, Fig. 2.]

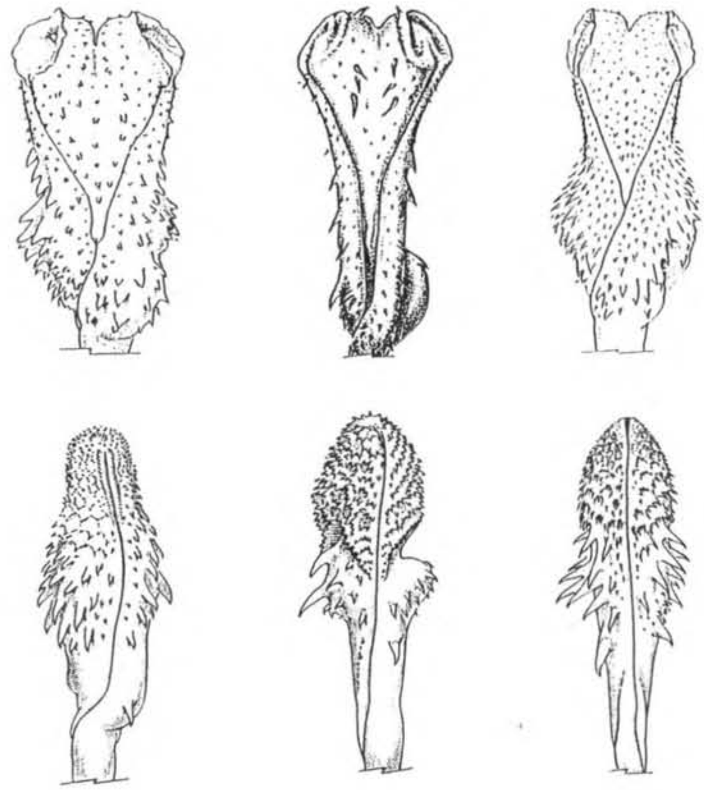

FIG. 3. Top row: Hemipenes of the type species of the genera "*Leimadophis*," "*Lygophis*," and *Liophis* [HISS Collection]. All were placed in the genus *Liophis* [Xenodontidae: Xenodontinae] by Dixon (1980) [cf. my Fig. 10]. In spite of the differences in the expansion of the body, all have the same major characters (e.g., disks) with minor differences in the size and distribution of spines. Bottom row: Hemipenes of three species of the genus *Tantilla* [Dipsadidae: Leptodeirinae: *T. coronata*, *T. atriceps*, and *T. nigriceps*]. Other than differences in the number, size, and distribution of spines, most differences are due to different degrees of expansion of the body during specimen preparation. Only *T. atriceps* clearly shows the degree of capitation, which is common to all [HISS Collection].

FIG. 4. The partly-everted hemipenis of *Phyllorhynchus*. The outline of the originally-observed lobes is dotted in. [Drawn by Brook Fehrenbach: HISS Collection.]

electrophoresis (Dowling et al. 1996) for this purpose.

Having watched mammalogists and ornithologists carefully prepare their specimens in the field (even at midnight), I am struck by the fact that herpetologists still tend to be in the "catch-em, kill-em, fill-em full of formalin, and throw-em in the can" mind-set. The world (including the herpetological world) has changed in the last half-century. It is clear from Zaher's (1999) paper that re-inversion from poorly prepared "field" specimens is never fully successful (see below) and that the proper preparation of everted hemipenes in the field is of major importance. We also need to photograph important specimens alive—to record their colors as well as patterns—and perhaps even record the shape of the pupils of their eyes, anything unusual about their head structures (e.g., nostril shapes and positions), and determine whether their dorsal body scales are juxtaposed or imbricate before preservation. [Immersion in formalin often shrinks the skin, making juxtaposed scales appear imbricate.] Of course we also should take tissue samples for genetic analysis, and perhaps blood samples for electrophoretic and cytogenetic studies.

While working with us at HISS (Herpetological Information Search Systems) Ms. Waite both processed and drew the Museum specimens utilized. Because we had no other everted hemipenes to compare for many of the exotic genera, it was not until after our five-year period at HISS had abruptly ended that we realized that many of the AMNH specimens processed (as described in her note) were still incompletely everted. Apparently, Myers did not recognize this either, resulting in their semi-everted states assumed to be "complete" in Zaher's (1999) extensive study—and my possession of many beautiful drawings—of incompletely-everted hemipenes.

One, of many objectives of ours at HISS was to provide figures of "important morphological characters" of the type species of every snake genus. We decided on a minimal approach: the scutellation of the head, a vertebra from the third quarter of the body, a hemipenis, and a skull or maxilla. To make this possible in the time projected: ten years [later reduced to five when a "restructuring" of National Science Foundation programs left us (and several other similar projects) without a sponsor], we had to restrict each of the figures to a single view. [The complete illustration of a vertebra, for example, requires five views.] Thus, we had only lateral views of the head, vertebra, and maxilla, and only a sulcate view of the hemipenis (*v.* Figs. 5 and 6). [Figs.10 and 11 also have this format.]

On the Response by Zaher and Prudente (2003)

Z&P comment (in part) as follows (p. 302): "...a more careful examination of the arguments and examples used by Dowling shows that his criticisms are founded upon two fallacious ideas: 1) that science is a matter of authoritative knowledge instead of a search for answers by empirical observation and test of hypotheses; [It has been a long time since I have had "science" explained to me!] and 2) that hemipenial morphology shows some special value

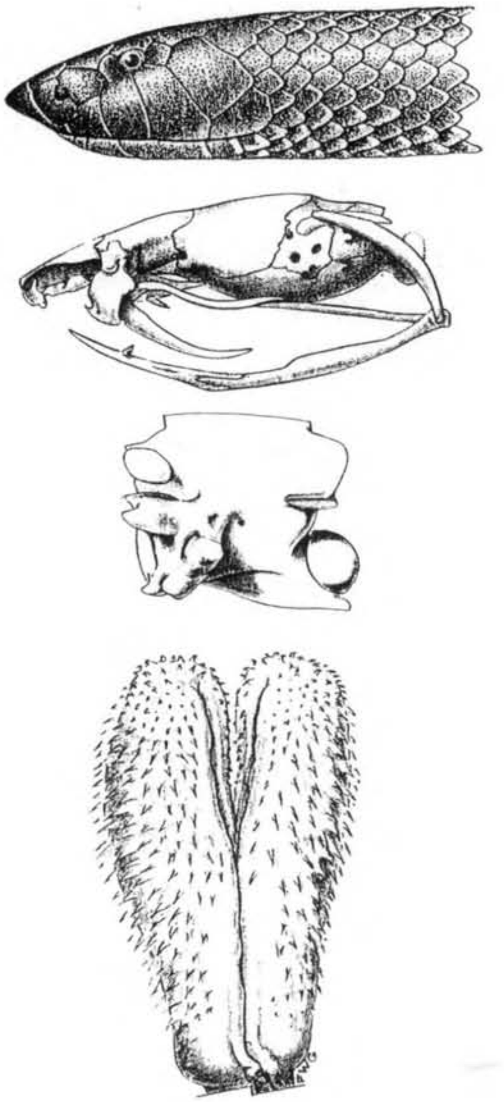

FIG. 5. HISS format [head, skull, posterior vertebra, and hemipenis] of *Atractaspis* ("Atractaspididae"). The apical lobes of the hemipenis are slightly inverted, but the forked centripetal sulcus and the change in size of the spines near the apex are visible. The head drawing is from Witte (1962), other figures are from the HISS Collection. (cf. Zaher 1999: Fig. 4U)

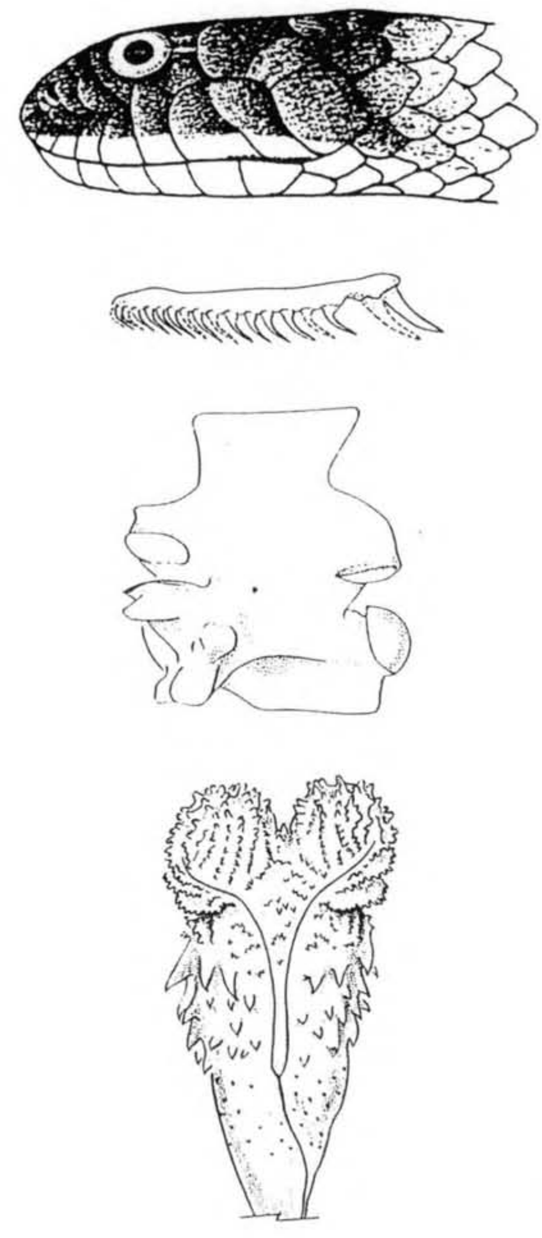

FIG. 6. HISS format of *Helicops* (Xenodontidae: "?Alsophiinae"). The hemipenis is slightly under-everted. The head drawing is from Miranda et al. 1982; other figures are from the HISS Collection (cf. Zaher 1999: Figs. 47–50U).

as a source of information at the detriment of other morphological complexes."

I believe that here, the shoe is on the wrong foot. Rather than arguing about whether my criticisms are valid or not, Z&P should be dissecting the uneverted hemipenis of *Conophis* (*v.* Zaher 1999: Figs. 40, 41) to see whether or not the members of this genus have apical disks—as reported by Wellman (1963) and Auth et al. (1998).

Their objection in reference to *Hydrops* is due to a misreading of my (2002) comment. I referred to Zaher's (1999) Fig. 52, which, although distorted, was a **correction** of my drawing of AMNH 36161, which was incompletely everted and failed to show the apex of the hemipenis.

Their second point, "2) That hemipenial morphology shows some special value as a source of information […] at the detriment of other morphological complexes," I believe to be half-true. I do believe that hemipenial morphology has especial value in establishing relationships among snake taxa (see below), but I do not see any "detriment" of other morphological characters thereby. Z&P are highly critical of my assessment of incomplete eversion and distortion in hemipenes that I have not personally examined. They also have another long segment on hemipenis preparation, much of which is similar to that by M&C. Again, if hemipenial morphology is so variable "at all taxonomic levels," why place so much importance on their preparation? Incidentally, the method employed in their reexamination of previously preserved hemipenes of *Siphlophis* hemipenes (Z&P 2003) is inappropriate. The tissues of the organs had already been fixed, so their overall shapes were unchanged by subsequent treatments. How about cutting the retractor muscles and everting a fresh specimen, or examining an uneverted organ? It is unfortunate that Zaher (1999)

was not encouraged to compare the everted hemipenes that he used in his major work with some inverted specimens—or to have them examined by some other knowledgeable herpetologist.

The value of hemipenes as indicators of relationships is primarily that they all have the same purpose and are used in the same fashion: to introduce sperm into the oviducts of the females of the same species. Thus, they are generally not affected by modes of locomotion, adaptations of sensory organs to changing conditions, or adaptations concerned with prey capture and handling.

The only adaptive change in hemipenes that I have discovered is in the Old World Sand-racers (Psamophiidae), which inhabit open desert grassland and sandy habitats. These snakes, unlike most, remain alert to possible predation during copulation, both male and female looking around in all directions (Fig. 7.). The members of this group (some seven genera with about 73 species) have lost all forms of hemipenis ornamentation, apparently as an adaptation to rapid withdrawal of that organ when the copulating pair is threatened (Fig. 8).

FIG. 7. A sketch, showing the alert postures of copulating psammophiids. [HISS Collection.]

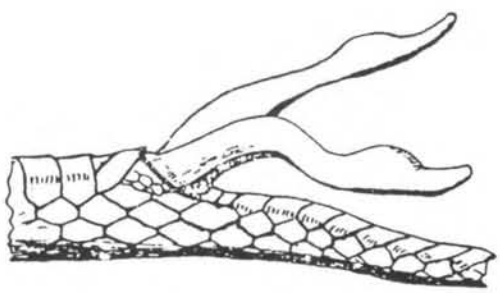

FIG. 8. Hemipenis of *Mimophis* [Psammophiidae] (From Domergue, 1962). Note the length of ~10 subcaudals; the *Psammophis* hemipenis in Bogert (1940: Fig. 14, ~3 subcaudals) is incompletely everted.

Thus, the evolution of hemipenial morphology differs from that of dental and skull characters, which are highly responsive to food adaptations, burrowing or habitat (e.g., the premaxilla in burrowing and other specialized snakes: Bogert 1947 (see my Fig. 9); or terrestrial vs. aquatic snakes: Malcolm Smith 1943:379, 439). It also differs from that of vertebrae, which are responsive to changes in locomotion and food handling (e.g., constrictors, racers, treesnakes, seasnakes).

On the question of my ability to recognize an incompletely-everted or poorly prepared hemipenis, I can only say that it is due to long experience and careful observation. Like a good auto mechanic (of the "old school"), who can tell you what is wrong with the car's motor by listening to it run for a minute or two, or a professional "birder," who can identify an almost invisible bird by a faint call or the flash of a wing—in the last several decades of study I have acquired an "eye" for details that suggest problems in the preparation of hemipenis specimens. These include having: 1) the apex (or apices) bowed over, 2) apical lobes of unequal length, 3) flattened or depressed apices, 4) the "end" of a sulcus spermaticus entering an apical depression, 5) a crooked sulcus, 6) a corrugated base, and 7) jagged or irregular margins of the organ.

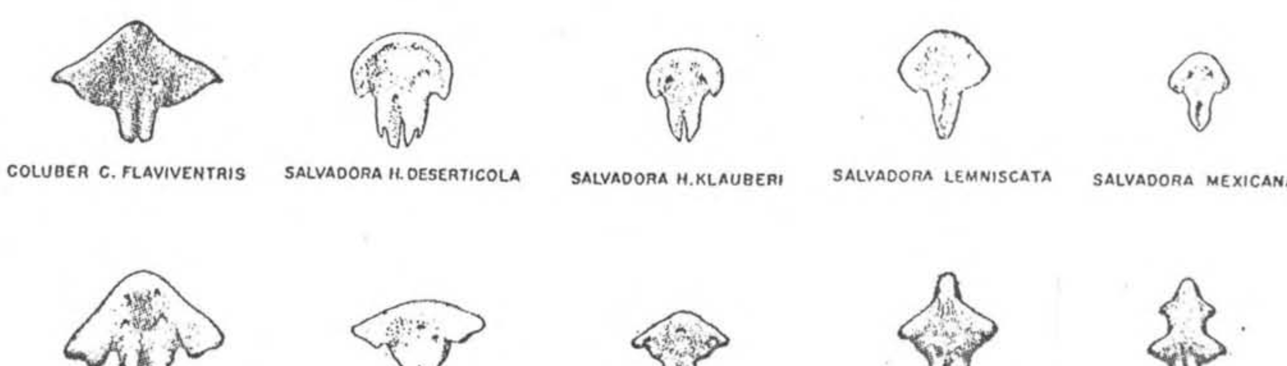

FIG. 9. Differences are shown in the adaptations of premaxillae within a subfamily: (Colubrinae), within genera (*Salvadora; Pituophis*), and in response to burrowing *(Pituophis c. sayi; Rhinocheilus).* [Abstracted from Bogert 1947.]

There are probably other indications as well, but these are a start. I am also suspicious when the members of a genus have vastly different hemipenial structure, or even if the members of a clade have unlike hemipenes.

With this background, when I obtained a copy of Zaher's (1999) photographic study of hemipenes, I immediately recognized that some of his illustrations were of misshapen and/or incompletely everted organs. After finding a significant number, I did a page-by-page survey of the entire study. [I had no idea of publishing this list, but under the present situation, with four herpetologists questioning my ability, I have decided to do so.]

There are five figures that I believe to be so inaccurate as to place the taxa in the wrong family. These are *Nothopsis* (Fig. 88, Upper), *Synophis* (Figs. 88, Lower, and 89, Upper), and *Xenopholis* (Fig. 95, Upper and Lower), genera which T. Pinou and I have recently recognized, on other than hemipenial bases, to be members of the vastly different family, Xenodermatidae (Dowling and Pinou 2003). The Philippine *Oxyrhabdium* (Fig. 6, Upper) belongs here also (*cf.* Leviton 1964, and my Fig. 10).

There have been no descriptions of the hemipenes of American xenodermatids, but Pope (1935:185) has a brief description of the hemipenis of the Chinese xenodermatid, *Achalinus spinalis*: "The hemipenis is excessively long and slender, extending to the sixteenth to seventeenth subcaudal plates, but is forked opposite the sixth." Malcolm Smith (1943:128) has a more detailed description of the allied Indian *A. rufescens*, giving a length of 24 subcaudals and forking opposite the 4th, with a brief statement on the hemipenis in *Fimbrios klossi,* indicating a similar structure in that xenodermatid. Both Brain (1959) and Broadley (1983:109) have photographs of the hemipenis of the Ethiopian xenodermatid, *Pseudaspis,* [Brain was mistaken in thinking that both hemipenes were everted.] and I have examined the hemipenis of another Ethiopian xenodermatid genus, *Mehelya* (Fig. 10). All of these xenodermatids have a pair of long, very slender apical lobes that are 2x or more longer than the hemipenial "body."

I anticipate that the hemipenes of the American representatives noted above will be found to have similarly elongated lobes when properly prepared and examined. [This might also be tested now by carefully slitting the asulcate side of the hemipenis, and looking closely for the slender apical lobes.]

Originally, I had intended to include minor inaccuracies (misshapen body, corrugated basal region, short or unequal apical lobes, incomplete expansion, crooked sulcus, etc., in this list of Zaher's (1999) illustrations, but found that this would include the majority of the figures in the paper. When I cut this to "moderate to significant inaccuracies, I still had 107 figures to list. As pointed out by Yuki (1997), "Unfortunately, a semi-everted hemipenis, prepared with Pesantes' [1994] technique [Similar to that described by Ms. Waite] will not produce a general shape similar to that of organs that are completely everted…." I must agree.

My final count is + 70 "significantly inaccurate" figures [e.g., those that omit significant structures or give erroneous information on the structure of the hemipenis depicted] of Zaher's (1999) total of about 165 illustrations of snake hemipenes (Appendix I). Thus, I find that more than 40% of Zaher's photographic representations of snake hemipenes are significantly inaccurate or misleading. Many others are far from good representations of the hemipenial morphology of the species depicted.

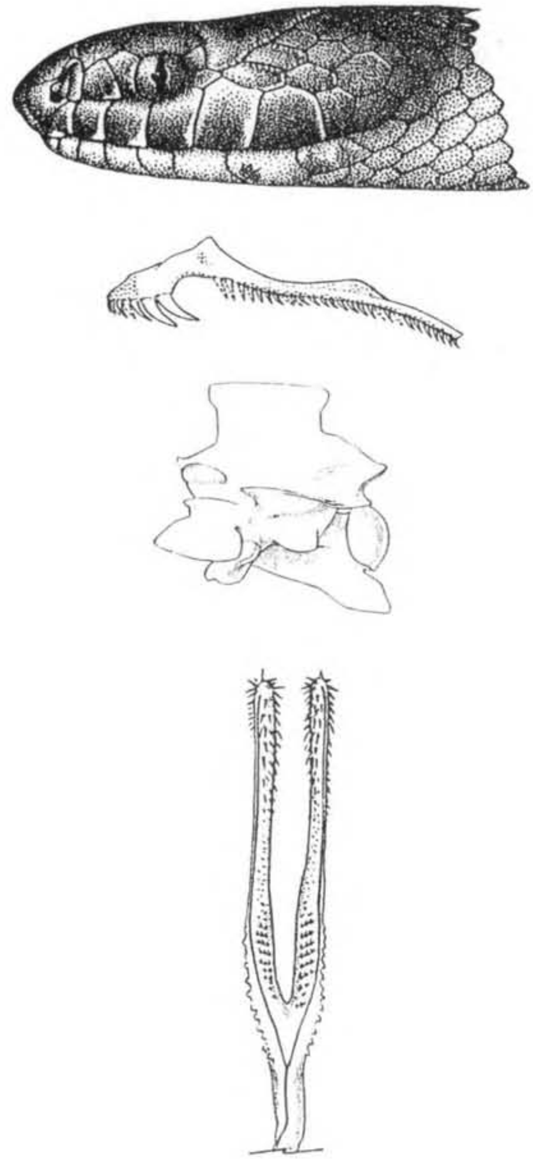

FIG. 10. HISS format of *Mehelya* (Xenodermatidae: subfamily *incertae sedis*). The enlarged, front-facing nostrils, the vertically elliptical pupil of the eye, the expanded zygapophyses of the vertebra, and especially the long, slender paired lobes of the hemipenis (which may not be completely everted) are typical of xenodermatids. The highly specialized maxilla is not typical of all xenodermatid genera, and the size and shape of the vertebral hypapophyses vary between genera. The head drawing is from Witte 1962; other figures are from the HISS Collection.

It is probably for this reason that Zaher failed to discover the several clades of xenodontids that were briefly described and named on the basis of morphology (with major emphasis on hemipenis structure) by Jenner (1981), and later further defined and allocated (but not named) on the basis of immunology by Cadle (1984 *et seq.*). The large proportion of poorly prepared specimens in Zaher (1999) obviously obscured the major hemipenial differences between clades. As a result, rather than his study resulting in a clearer view of xenodontid clades and their interrelations, he was forced to resort to an alphabetical arrangement of presentation!

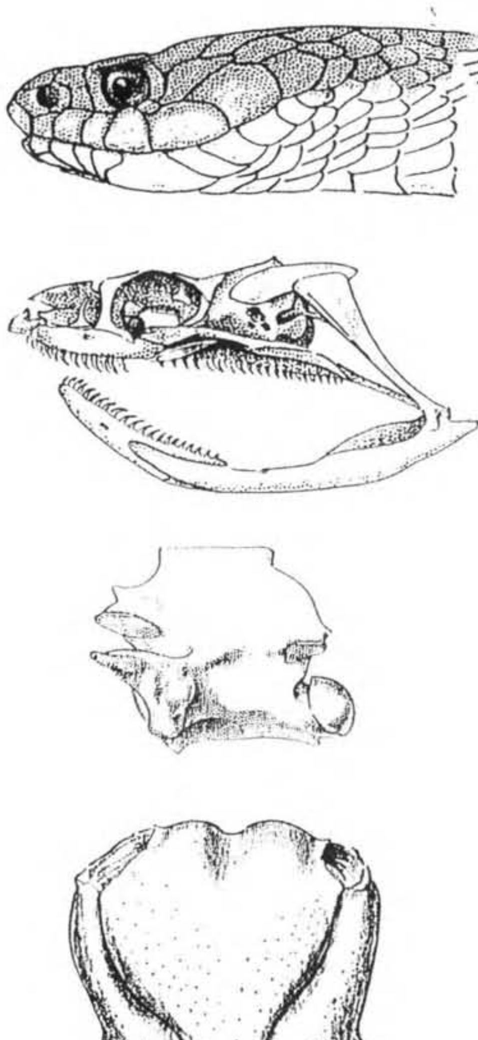

FIG. 11. HISS format of *Xenodon* (Xenodontidae: Xenodontinae). Note the semi-nude apical portion of the hemipenis with the pair of disks. The hemipenis is slightly[?] over-expanded. The dagger-like rear tooth of the maxilla is barely visible. [HISS Collection]

SUMMARY AND CONCLUSIONS

This review began as a reply to the two responses that were elicited by my brief review of Z&P's (1999) note on "Infraspecific variation of the hemipenis...." It has evolved into comments on hemipenis preparation, adequacy of photographic depiction, a brief review of Zaher's (1999) major work, and a brief history of my work on hemipenes and snake relationships. Much of the "sound and fury" could have been avoided if the various responders had made a re-examination of the contested hemipenial morphology [e.g., by dissection], rather than writing confrontational papers. I had previous experience with the apparently different conditions in snakes reported by Z&P (1999) with similar deeply-bilobate hemipenes (e.g., *Agkistrodon*), and pointed out (Dowling 2002) that the "folded-over" condition was caused by the shrinking of the (uncut) retractor muscles during hemipenial preparation.

Z&P did not believe me, but rather than making the pertinent observations—preparing other hemipenes after cutting the retractor muscles, or dissecting one of the "folded-over" specimens to see if the retractor muscles were, indeed, tightly-stretched between the base and the lobes (and between the lobes) of the hemipenis—they contested it in print (Z&P 2003). They cited Zaher (1999) as the authority who demonstrated that "hemipenial features are surprisingly variable at all taxonomic levels within colubroids." [Incidentally, it seems strange that Zaher failed to illustrate the hemipenis of the type genus of xenodontine snakes (*Xenodon*) (*v.* my Fig. 11).]

This view presented us with only two alternatives: (1) either Zaher (1999) is correct in his findings that hemipenis morphology is highly variable within genera and clades—and thus hemipenes cannot be used in the recognition of these taxa [in opposition to the views of Cope (1893, 1895), Bogert (1940 *et seq.*), and many others, including mine], or (2) there is something else that has obscured his view of hemipenial morphology.

As I show in this brief review of Zaher (1999), the apparently significant variation between hemipenes within a genus, or within a clade, as shown by Zaher, is primarily caused by improper preparation of the organs for study.

His illustrations of the hemipenes of seven species of *Arrhyton* (Fig. 33-37U) are a prime object-lesson. They appear to be highly variable in all respects. Whereas *A. vittatum* and *A. landoi* (Fig. 33) have a pair of fairly elongate apical lobes, only *A. taeniatum* (Fig. 34L) otherwise shows a (slightly distorted) similar configuration. *Arrhyton exiguum* (Fig. 37U) obviously has paired lobes, but the entire hemipenis is so distorted that it appears unlike the previous three. *Arrhyton callilaemum* (Fig. 34U) has a pair of tiny apical projections, but no lobes, whereas *A. funereum* (Fig. 35) and *A. polylepis* (Fig. 36) have no trace of paired lobes. In my opinion, all species of *Arrhyton* have paired apical lobes much like those seen in Figs. 33 and Fig. 34L. The lobes possessed by *A. callilaemum, A. funereum,* and *A. polylepis* were not everted in the preparation of these hemipenes. A curator at "MPMH" [?: not listed in Leviton et al. 1985] should split the asulcate side of hemipenis numbers 22703, 22707, and 22789, and carefully look for the inverted apical lobes that I am sure lie inside.

The situation with the genus *Conophis* is another illuminating section. Although Zaher's figures 40U&L, and 41U [*C. vittatus*] vary considerably, none shows the apical disks recently reported by Auth et al. (1998) for *C. vittatus* (the type species), or those previously reported and illustrated by Wellman (1963) in his revision of the genus, who also stated (p. 289), "There are no apparent hemipenial differences among the species of the genus *Conophis*." Zaher (1999) listed this reference, but apparently ignored the description of disks—as well as their illustration.

Similarly, curators at the AMNH and other museums should check for uneverted hemipenes among their specimens that I list in Appendix I. I am confident that inverted lobes (and/or disks) will be found. Further, I would hope that herpetologists working in the field would take the time to properly prepare at least one fully everted and expanded hemipenis of the unusual snakes (and

lizards) that they find. Zaher's (1999) paper convincingly demonstrates that half-everted "field preparations" cannot be "repaired" and successfully utilized for systematic analysis.

Acknowledgments.—All drawings are by Frances Waite [HISS Collection] unless otherwise indicated.

Sophisticated information on reproduction and mating systems of non-avian reptiles is growing rapidly, and important advancements span a wide range of disciplines (Campbell and Brodie, 1992; Duvall et al. 1992, 1993; Gans and Crews 1992; Gibbs and Weatherhead 2001; Schuett et al. 2002 a, b; Shine 2003). Notwithstanding this growth there are obvious and significant deficiencies in knowledge of certain taxa, especially in snakes. Studies of endocrine patterns in this group involve only a limited number of species, and most of them are New World natricines (Moore and Lindzey 1992; Whittier and Tokarz 1992). Consequently, diversity of proximate mechanisms is lacking which seriously impedes our ability to develop robust evolutionary models (Drickamer and Gillie 1998). Many important research questions regarding proximate regulation of reproduction need to be addressed, and these include seasonal patterns of plasma sex steroids, differential functions of steroids on development and activation of behavior, and the dynamics of free- and bound steroids (and their binding globulins) with respect to receptor function (Bonnet et al. 1994, 2001, 2002; Breuner and Orchinik 2002; Jennings et al. 2000; Moore and Lindzey 1992; Schuett et al. 2002a; Seigel and Ford 1987; Whittier and Tokarz 1992).

There are, for instance, few studies of steroid profiles of pregnancy in snakes (Whittier and Tokarz 1992), and no studies of sex steroid profiles in cases where females are unequivocally utilizing sperm from long-term (over winter) storage, referred to as long-term sperm storage (LTSS; Schuett 1992). In numerous species of viperids, LTSS is an important (or even obligate) component of reproduction (overviewed by Schuett 1992; Sever and Hamlett 2002). Although there are no *a priori* data to suggest that there are causal connections between LTSS, ovarian activity, and sex steroid profiles during pregnancy, we cannot assume they do not exist (see Ameida-Santos et al. in press). For example, if females that mate in spring ovulate earlier, perhaps due to the act of coitus itself (e.g., Mendonça and Crews 1990), development and birth of offspring might be accelerated compared to females with LTSS and no sexual activity in spring.

While conducting field behavioral endocrinological studies on the Western Diamond-backed Rattlesnake (*Crotalus atrox*) in the area of the White Tank Mountains (39 km W of central Phoenix, Maricopa County, Arizona), an adult female was collected by one of us (GWS) on 17 September 1999, 2110 h, on Sun Valley Parkway, 15.2 km W of the McMicken Dam Spillway. Due to her good state of health and high body mass, she had not likely produced a litter that summer. Thus, she was a good candidate for having been mated in late summer (cf. Bonnet et al. 1994, 2002; G. Schuett and R. Repp, unpubl. data) and to test for LTSS (Schuett 1992). It is not established that female *C. atrox* show LTSS, and it is important to know whether or not copulations restricted to the first mating season (late summer and autumn) are sufficient for the initiation of pregnancy the following spring (Schuett 1982, 1992).

In south-central and southern Arizona and other areas of its expansive distribution, *C. atrox* shows sexual behavior (i.e., courtship, coitus, male-male aggression) in two distinct calendar periods. Based on the events of the male's reproductive cycle (e.g., peak spermatogenesis and levels of plasma sex steroids in late summer; meiotic regression in autumn) and timing of ovulation and fertilization in late spring, the first mating season is from late August to at least mid October, which includes the monsoon season (mid July to mid September). Following hibernation (mid November to late February), the second mating season is from early March to mid May, and sexual activity can occur at or near traditional communal dens during emergence (Repp 1998; Schuett et al. 2001). This bimodal pattern of mating seasons in *C. atrox* was established by long-term studies using radiotelemetry, observations in the field, published accounts, and personal communication (e.g., Klauber 1972; Schuett et al. 2001, in press; Taylor et al. 2004; G. Schuett and R. Repp, unpubl. data; S. Beaupre, pers. comm.; E. Nowak, pers. comm). Detailed information on the tim-

ing of mating seasons of pitvipers is reviewed in Schuett (1992), Aldridge and Duvall (2002), and Schuett et al. (2002a).

The goal of this paper is to report for the first time unequivocal LTSS in a female Western Diamond-backed Rattlesnake (*Crotalus atrox*), and to describe the profile of several important circulating steroid hormones (testosterone [T], 17β-estradiol [E2], progesterone [P4], and corticosterone [CORT]) during her pregnancy.

Methods

Subject.—At the time of capture, the subject was 740 mm SVL, 50 mm TL, and 435.0 g. Her identification number was CA-149. She was maintained in strict isolation in a glass enclosure (91 cm L x 30 cm W x 25 cm H) with a screen cover, supplied with newsprint as a floor covering and heat tape (8 cm wide) was situated beneath and across the front end of the cage (35°C). Artificial lighting (eight 40 W fluorescent tubes) positioned 3 m above the cage was electronic timer-controlled to simulate natural (Arizona time) photoperiod year round. Laboratory rodents (hamsters and rats) were offered as food every 10 days until 15 November 1999, and water was available in a glass bowl *ad libitum*. From 15 November 1999 to 1 March 2000, CA-149 was maintained under conditions to simulate hibernation (Schuett et al. 1997b).

Collection of blood and plasma.—Sampling periods (N = 11) occurred in September 1999, and from April to August 2000 (Fig. 1). In the laboratory, the subject was gently removed from her individual enclosure using a hook and/or grabber tongs, and secured in a standard squeeze-box. This procedure was done quickly (1–3 min) to avoid handling stress and possible effects on sex steroid levels (Schuett et al. 2004). Once secured, 1.0 ml of blood was collected from tail vessels, generally within 1 min, using a 1.0 ml sterile tuberculin syringe (25-G5/8") treated with porcine-derived heparin sodium (1,000 units/ml). The subject was returned to her enclosure immediately following this procedure. Blood was transferred to a 1.5 ml centrifuge tube and immediately placed on ice for several minutes until it could be centrifuged (Taylor and Schuett 2004). All blood samples were centrifuged for 4 min at 6000 rpm, and plasma was collected and transferred to 1.5 ml Nalgene® centrifuge tubes for storage in an ultra-low freezer (-80ºC) until radioimmunoassays (RIAs) could be performed (<1 year).

Radioimmunoassay of plasma.—The general procedures for conducting RIAs for measuring concentration of plasma T and CORT (Schuett and Grober 2000; Schuett et al. 1996, 1997b, 2002a, in press; Taylor and Schuett 2004) and E2 (Schuett et al., *in press*; Taylor and Schuett 2004) are published, and those for P4 will be discussed in detail below. Briefly, RIAs of T, CORT, and E2 included validation (quantitative recovery and parallelism), and samples were analyzed in duplicate (N = 22 for each steroid). Two RIAs were performed for T; the intra-assay coefficients of variation (CV) were 9.1% and 11.1%, and the inter-assay CV was 11.9%. One RIA was performed for CORT, and the intra-assay CV was 2.4%. Two RIAs were performed for E2; the intra-assay CVs were 7.9% and 12.5 %, and the inter-assay CV was 11.9% Values for T, CORT, and E2 are presented as arithmetic means ± 1 SE (ng/ml).

For RIAs of P4, antibody-coated tubes and radiolabeled P4 were purchased from Diagnostic Products Corporation, Los Angeles, CA (catalog numbers TPG1 and TPG2). Standards were prepared be serial dilutions of a stock solution in phosphate buffered saline (PBS) containing 0.1% gelatin. Snake plasma (50 μl) plus 350 μl of PBS were extracted in 5.0 ml of diethyl ether (Fisher Scientific). After removing and drying the ether layer, the sample was re-suspended in 200 μl of PBS-0.1% gelatin. Extraction recovery of H^3-progestestrone (New England Nuclear, Boston, MA, NET-381) was 69%. The entire 200 μl of extract plus an additional 100 μl of PBS-0.1% gelatin was dispensed into the antibody tubes. Following addition of 1.0 ml of tracer, the tubes were incubated at room temperature (21°C) for 4 hr. Quantitative recovery of P4 added to *C. atrox* plasma was 100%. Parallelism was demonstrated between the inhibition curve for the standards and dilutions of *C. atrox* plasma for plasma volumes > 12.5 μl. A single RIA was performed and assay samples were run in duplicate (N = 22). The intra-assay coefficient of variation was 8.7%. Values for P4 are presented as arithmetic means ± 1 SE (ng/ml).

Ultrasonography.—To determine size of follicles, the approximate time of ovulation, and presence of embryos, ultrasound imaging (Dynamic Imaging, Concept/MC) was performed multiple times from the time of capture through July 2000. Size of follicles was determined as best as possible to the nearest millimeter, and numbers were estimated. Embryos were counted but not measured.

Results

The reproductive pattern and plasma steroid profiles of CA-149 at the time of her capture to 5 days post-partum are shown in Fig. 1.

On 17 September 1999, at the time of capture, the concentration of T and P4 was relatively higher than E2; CORT was relatively high (67.28 ng/ml). Ultrasound revealed multiple follicles (> 5) that were ≤ 3 mm in width, and thus not in the process of primary follicular growth, i.e., yolk deposition (Aldridge 1979; Schuett 1992).

On 3 April 2000, the first post-hibernation measurement, E2 was elevated (highest level measured), CORT levels were similar to the value obtained on 17 September, and both T and P4 were relatively low. Ultrasound revealed growth of the follicles since 17 September, presumably occurring from 1 March to 3 April. Multiple clustered follicles of ≥ 35 mm in width were detected. On 10 May 2000, E2 had decreased, and on 10 June E2 was at its lowest concentration remained near (or at) that 1.0 ng/ml throughout gestation and five days following parturition. From 10 May and following parturition, the profile of T tracked that of E2. Ultrasound revealed that ovulation had occurred by 10 May (i.e., multiple ova ≥ 55 mm were arranged linearly), and seven embryos were detectable by 1 July. The concentration of P4 increased sharply following10 May, and its highest concentration was on 1 July. Subsequently, P4 decreased sharply up to and several days beyond the date of parturition (22 August). CORT increased after 3 April, and reached its highest spring concentration on 10 May (263.89 ng/ml). Following ovulation, CORT sharply declined to baseline by 10 June, and levels subsequently increased a second time, peaking from 29 July to 12 August, and decreasing by 18 August. On 22 August, levels of CORT rose to the highest concentration at the time of parturition. Seven offspring (4 males, 3 females) were of healthy appearance and normal size, and no infertile masses were present.

Discussion

This is the first account to unequivocally demonstrate LTSS in female *C. atrox* (Schuett 1992), and among the few descriptions of steroid patterns of pregnancy in a viperid snake (Bonnet et al. 2001, 2002; Saint Girons et al. 1993; Taylor et al. 2004; Tsai and Tu 2002). We suggest that the present female mated in late summer or fall of 1999, showed LTSS during winter, ovulated in May, and the stored sperm had normal fertilizing capacity. Because there are no reliable data to support the view that LTSS extends beyond a single reproductive season, mating in late summer or autumn is the most parsimonious conclusion. Moreover, there is little evidence to support a spontaneous parthenogenetic event because such rare cases of reproduction in captive snakes have never resulted in healthy litters composed of both sexes (Schuett et al. 1997 a). In the present case, timing of reproductive events, such as follicular growth and ovulation, as well as patterns of plasma sex steroids, were indistinguishable from wild female *C. atrox* that have the opportunity to mate in spring (Taylor et al. 2004). In most North American viperids, vitellogenesis and follicular development appear to be largely confined to summer and autumn, and females thus enter hibernation with large, yolked follicles and subsequent growth of follicles may occur in spring (Aldridge 1979; Aldridge and Duvall 2002; Schuett 1992). In low elevation regions of south-central and southern Arizona, these follicular events in *C. atrox* appear to be confined to spring on a biennial basis (Taylor et al. 2004; G. Schuett and R. Repp, unpubl. data; S. Beaupre, pers. comm.; but see Rosen and Goldberg 2002). Although Tinkle (1962) reported that female *C. atrox* from northwestern Texas had enlarged follicles in autumn, the observations by Fitch and Pisani (1993) of *C. atrox* from Oklahoma are similar to our findings and indicate that the majority of follicular yolking occurs in spring. Based on these incongruent data, further studies will be required to better understand the role of environmental factors and geographic location in the timing of follicular development in this species (Rosen and Goldberg 2002).

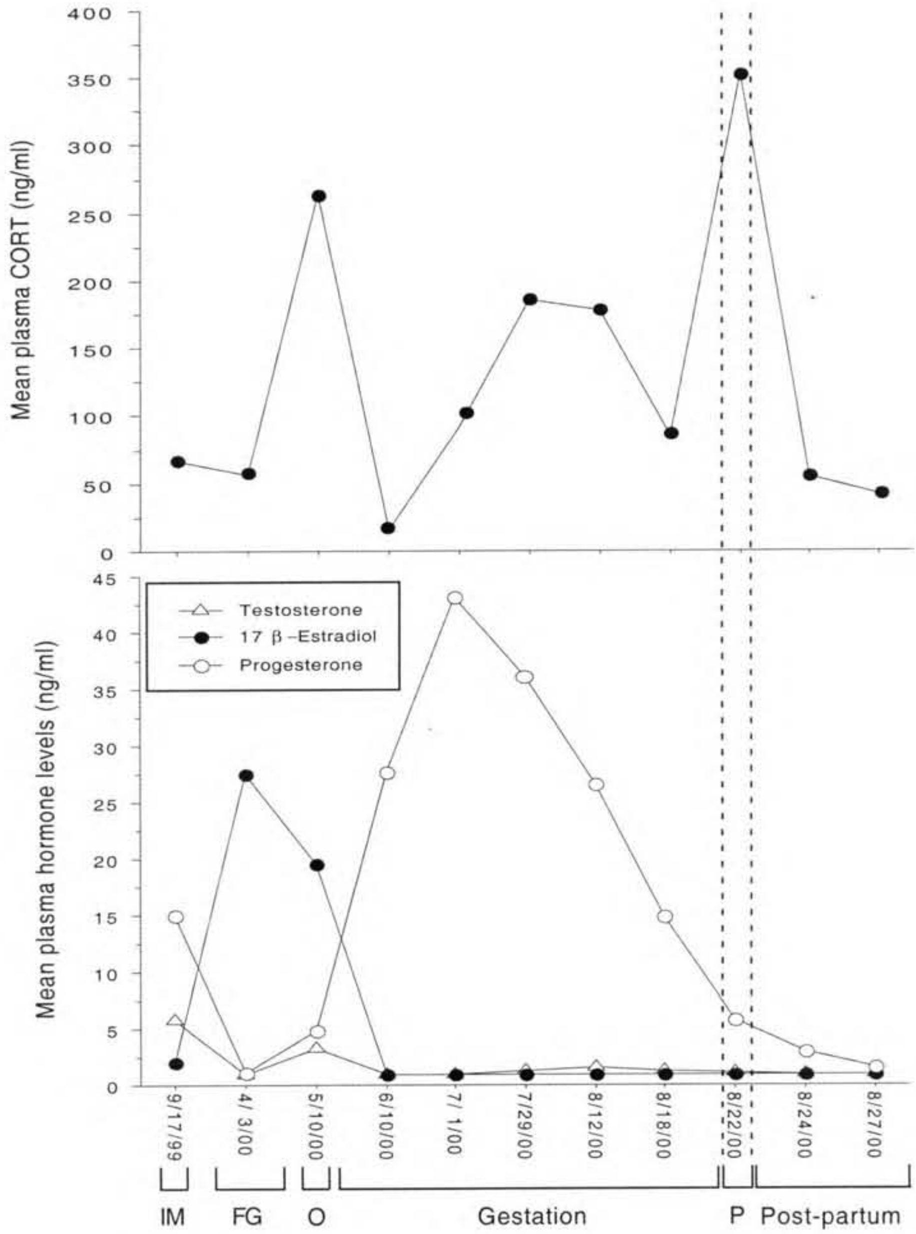

Fig. 1. Reproductive events and mean plasma sex steroid profile of the female *Crotalus atrox* (CA-149) described herein. CORT = corticosterone. IM = immature follicles. FG = follicular growth. O = ovulation. P = parturition.

There are few studies on female snakes regarding patterns of circulating steroids related to sexual activity and pregnancy to make robust comparisons (Chan et al. 1973; Highfill and Mead 1975 a, b; Kleis-San Francisco and Callard 1986; Whittier et al. 1987); data on vipers are very limited (Bonnet et al. 1994, 2001, 2002; Saint Girons et al. 1993; Taylor et al. 2004; Tsai and Tu 2001). Taylor et al. (2004) investigated plasma steroids in free-ranging pregnant *C. atrox* in south-central Arizona, and plasma steroid profiles of the present female did not deviate from free-ranging individuals that have a second opportunity to mate in spring. Furthermore, the steroid data of the present female are, in general, similar to those reported for other viperids (Bonnet et al. 2001, 2002; Tsai and Tu 2001), as well as other viviparous squamates (Edwards and Jones 2001; Martínez-Torres et al. 2003; Xavier 1987).

Most authors report elevated E2 levels during follicular growth, and subsequent declines during gestation (Bonnet et al. 2001; Taylor et al. 2002), and it is suggested that high post-ovulatory P4 levels suppress E2 levels during pregnancy (Bonnet et al. 1994; Edward and Jones 2001). The high P4 levels during autumn in the present female may have been associated with sexual receptivity

and/or ovarian function (Whittier and Tokarz 1992). There was, however, no evidence of follicular growth at that time based on ultrasound results. It is doubtful that yolk deposition occurred from 15 Nov.–1 Mar.; nonetheless, it is a possibility because the next ultrasound measurement was not taken until 3 April. Although few authors have reported on androgen levels in female snakes (Saint Girons et al. 1993), these are also generally low during gestation. Comparison of CORT levels at the time of birth to other viperid species is not possibly due to lack of information; the pattern of CORT levels in *C. atrox* reported by Taylor et al. (2004) were essentially identical to those we report here.

The functional roles of estrogens (e.g., 17β–estradiol), progestins (e.g., progesterone), and androgens (e.g., testosterone) in female reptiles have been reviewed (Whittier and Tokarz 1992). Despite the fact that a robust understanding of the functions of steroids is lacking for female snakes, estrogens and progestins can have relatively straightforward effects on behavioral processes related to sexual receptivity (McNicol and Crews 1979; Whittier and Tokarz 1992; Whittier et al. 1987; Wu et al. 1985), vitellogenesis and yolk deposition (Garstka et al. 1985; Ho 1987; Ho et al. 1982; Wilson and Wingfield 1992), and maintenance of pregnancy (Bonnet et al. 1994, 2001; Chan et al. 1973; Custodia-Lora and Callard 2002; Edward and Jones 2001; Tsai and Tu 2001; Xavier 1987).

Reproductive tissues of females can produce androgens (testosterone, 5α-dihydrotestosterone), but little information concerns their function(s) (Edwards and Jones 2001). There is, however, increasing evidence that androgens might play a role in follicular maturation and oviductal maintenance (Staub and DeBeer 1997). Androgens in females (and males) can be converted in the central nervous system (and other regions) to estrogens (i.e., aromatization) and other steroids (Callard et al. 1977, 1978); nonetheless, they also might have direct involvement in normal organization-activation processes (Staub and DeBeer 1997).

The significance of plasma corticosterone (CORT) in reproduction is not well known in female reptiles, and results are equivocal (Girling and Cree 1995; Wilson and Wingfield 1992). But several studies show its positive association with seasonal timing of sexual behavior, vitellogenesis and yolk deposition, mid-pregnancy anorexia, and extreme (i.e., peak) levels during parturition (Taylor et al. 2004; Wilson and Wingfield 1992; this study). The function of CORT and corticotropin-releasing hormone (CRH) during pregnancy and parturition has been studied rather extensively in humans and sheep models; the sharp spike in plasma CORT at parturition in humans, sheep, and snakes (this study) may derive from multiple origins (Bell et al. 1997; Petershack et al. 1999). Because the source of plasma CORT in pregnant snakes is not understood (i.e., it is probably not limited to strict adrenal involvement), fetal, placental, and other sources should be considered based on results of mammalian systems (Smith 1999; Weiss 2000). In *C. atrox*, plasma CORT levels are highly elevated during parturition (see Fig. 1), exceeding by two-fold the levels observed in male *C. atrox* that have been exposed to moderate handling stress (Schuett et al. 2004). Nonetheless, unlike stressed males which appear agitated and assume defensive postures, female *C. atrox* are unremarkable and calm prior to and during parturition. Therefore, the role of CORT in both physiological and behavioral processes in snakes, as in other vertebrates, appears to be complex and multi-functional.

In conclusion, we demonstrated that LTSS operates effectively in *C. atrox* resulting in pregnancy and normal offspring. In a laboratory setting, LTSS and lack of spring mating did not modify timing of reproductive events such as vitellogenesis, yolk deposition, ovulation and fertilization, and parturition. Furthermore, levels of plasma sex steroids in the present female were comparable to those of free-living pregnant female *C. atrox* that had the opportunity to mate in spring (Taylor et al. 2004).

Acknowledgments.—Numerous people participated in fieldwork related to this work, and we are especially appreciative of the generous help of the Schuett family (Laura, Laudon, and Emory), Jack O'Leile, Roger Repp, and Ryan Sawby. Dale DeNardo and Emily Taylor provided critical assistance with ultrasound imaging. We benefited from discussions with Steve Beaupre, Erika Nowak, and Roger Repp on the reproductive biology of *C. atrox*. Funding was by a Research Incentive Award, and a Research Creative Activities Award (Arizona State University West) to GWS. Zoo Atlanta graciously provided financial assistance in the preparation of this manuscript. The present research was approved by the IACUC at Arizona State University (98-429R to GWS).

Although factors influencing turtle offspring prior to nest emergence have received considerable attention by researchers (Gutzke and Crews 1988; Janzen et al. 2000; Packard and Packard 1987), the activity of neonates following their emergence from the nest is poorly understood (but see Burger 1976; Butler and Graham 1995; Keller et al. 1997). Previous field research has produced valuable information on several aspects of neonate ecology for several species (Brewster and Brewster 1991; Butler and Sowell 1996; Janzen 1993). A thorough understanding of life history patterns for many species is absent, however, and some existing information is conflicting (e.g., Congdon et al. 1999; Janzen et al. 2000). The lack of knowledge is primarily due to the cryptic nature of neonates and various logistical problems associated with studying small animals in the field. Recent advances in radio telemetry technology such as decreased transmitter size and increased battery life facilitate tracking small neonate turtles for a longer duration.

We studied nest dispersal and habitat use in neonate box turtles using a relatively new, very small radio transmitter. Few studies have been conducted using telemetry on neonate turtles (e.g., Butler et al. 1995), and none has focused on nest dispersal and habitat use of neonate box turtles.

The study was conducted at Rhodes-France Boy Scout Reservation (RFBSR) located in western Shelby County, Illinois, USA (39°19'N; 89°02'W), from March to April 2002. Two nests were located by radio tracking gravid female turtles during summer 2001 (Flitz 2003). The nests were sited in relatively open areas next to a tree stump in a grassy field and at the edge of a fire trail (see Flitz 2003 for more description). Nest disturbance was prevented by using excluder devices, made of hardware cloth of 0.6 cm^2 mesh and 30 cm diameter with walls buried 15 cm into the ground, around the nest until the end of the 2001 activity season. Upon hatching and emergence, neonate turtles from both nests (clutch sizes were 4 and 5, respectively) were collected, brought to our laboratory and allowed to overwinter in an outdoor enclosure (1.5 x 1.5 m) under ambient conditions. Each turtle was marked with a unique series of notches in the marginal scutes. This facilitated identification and placement back at the proper nest site the following spring.

After overwintering, single-stage radio transmitters (model LTM, Titley Electronics, Australia; 0.95 g) were attached to the carapace of six randomly chosen neonates (three from each clutch) using a non-toxic silicon adhesive (Fig. 1). Each transmitter cost approximately US $170, had an average lifespan of 28 days (pers. obs.; D. Titley, pers. comm.), and did not contain a thermistor. We relocated the subjects using a Telonics TR2 receiver (159.000-160.000 MHz) and a 6-element Yagi antenna. On average, the transmitter represented 13.4% of individual body mass (mean ± 1 S.E. mass of neonates = 7.11 ± 0.10 g). At the time we designed this study, the LTM model was the smallest transmitter of this longevity being manufactured for attachment on turtles. We concede that this mass exceeds normal guidelines for relative mass of transmitters (usually 5–8%, and rarely up to 10%; Cochran 1980; Richards et al. 1994); however, we did not observe differences in the mobility of neonates outfitted with these transmitters (discussed below).

On 30 March 2002, all neonates were returned to their respective nest sites at RFBSR and allowed to disperse. Each neonate was located 15 times between 0900 and 1700 h on an alternate day cycle (study duration = 32 days), and locations were marked with forestry flags. Upon relocation, air temperature at 1 m above ground (±1° C), and distance (±1 cm) and compass bearing from the previous location were recorded. Many movements were of small magnitude and were within the margin of error of most handheld Global Positioning System units, so we did not take GPS readings. If the turtle moved less than 30 cm from the previous

TABLE 1. Mean distances moved between relocations (m ± 1 S.E.) and microhabitat characteristics (of a 1 m^2 plot centered at point of relocation) for telemetered neonate box turtles (*Terrapene carolina*) at Rhodes-France Boy Scout Reservation (RFBSR), Shelby County, Illinois, between 30 March and 27 April 2002. Means are based on values recorded at 15 relocation points per subject and 75 randomly-selected sites at RFBSR.

	Feature of microhabitat							
Subject #	Distance moved (m)	% bare ground	% leaf litter	% herbaceous vegetation	% woody vegetation	% canopy closure	vegetation height (cm)	light intensity (lux)
202	1.14 ± 1.40	11.9	58.4	28.6	1.3	41.6	5.6	504.9
203	1.14 ± 1.39	48.3	34.5	12.2	5.0	61.3	7.7	442.9
204	2.35 ± 1.37	22.0	39.7	33.0	6.0	31.0	7.0	512.1
random	n/a	15.5	26.6	47.2	10.9	71.3	37.4	138.7

location, the exact distance was recorded but we did not mark the new position with another flag to minimize the physical obstructions within the immediate vicinity. We also recorded the following parameters in discrete categories at each relocation: sky condition (full sun, some clouds, mostly cloudy, overcase), amount of subject exposure (full exposure, partially concealed, fully concealed, buried), and subject activity (stationary, walking, eating, other).

On 30 April 2002, we revisited all relocation points and completed an analysis of the habitat within a 1-m area centered around each point (methodology follows Flitz 2003; Wilson 1998). The following measurements were recorded: % bare ground, % leaf litter, % herbaceous cover, % woody vegetation, % canopy cover (recorded using a densiometer), maximum vegetation height (± 1 cm), and light intensity at the ground surface (in lux; Extech Instruments light meter). Values for these parameters were compared to those measured at 75 randomly chosen sites within RFBSR recorded in April 2001 (Flitz 2003). Between 2001 and 2002, we did not observe drastic changes in vegetation characteristics and the pattern of human use of RFBSR remained the same.

Three turtles from the same clutch had moved less than 0.5 m in

FIG. 1. Neonate (36 days post-emergence) box turtle, *Terrapene c. carolina*, with 0.95 g transmitter. Glossy area on turtle's left dorsolateral surface is area where transmitter had been attached with silicone adhesive.

the first five days following their release. On the sixth day, the transmitters were discovered without the turtles within 0.5 m of their last locations. The presence of marks resembling tooth impressions on the resin casing of the transmitters suggests that a mammalian predator had eaten these subjects. Because of this, we discarded all data from the depredated subjects and base the remainder of our results on the remaining three neonates. The remaining telemetered turtles survived the duration of the study, and one of the non-telemetered turtles was observed 18 days into the telemetry period within 10 m of its nest location.

The total distance moved by our subjects during the study averaged 21.94 ± 5.46 m. Distances moved between relocations ranged from 0 to nearly 7.5 m, although the mean distance moved was on the lower end of that scale (Table 1). Minimum convex polygon estimates of home ranges averaged 39.96 ± 27.00 m^2 (Jennrich and Turner 1969). These home range areas are based on a limited sample (15 relocations per individual) and thus should be interpreted with caution. Subjects moved within the area around the nest site and were most often encountered motionless underneath a layer of leaf litter (36 of 43 observations). Air temperature at the time of relocation ranged from 9 to 27°C. The relationship between temperature and distance moved was not determined because subjects could have moved at any time between two relocations.

Sites where we relocated our subjects had less canopy closure ($\chi^2 = 44.8$, $p < 0.001$) and higher light intensity ($\chi^2 = 41.6$, $p < 0.001$) than randomly-chosen locations within RFBSR (Kolmogorov-Smirnov tests; Table 1). Light intensity was inversely correlated with canopy closure ($r^2 = 0.22$, $p = 0.001$) and we recorded higher air temperatures at the time of relocation at sites with higher light intensity ($r^2 = 0.11$, $p = 0.03$). Of the measured microhabitat characteristics, subjects were found in sites that had more leaf litter ($\chi^2 = 11.2$, $p = 0.007$), less herbaceous cover ($\chi^2 = 16.7$, $p < 0.001$), and shorter vegetation height ($\chi^2 = 28.1$, $p < 0.001$) than random sites. Relocation sites did not differ from random locations in the percent bare ground or percent woody vegetation available.

Following their emergence from the nest, neonate box turtles at RFBSR used habitats having characteristics that differed from randomly-selected areas. In the days immediately following emergence from the nest, this pattern of use was likely influenced by

the nest site itself. As elsewhere (Congello 1978; Messinger and Patton 1995), female box turtles at RFBSR tend to excavate their nests in relatively open habitat (see Flitz 2003 for quantified habitat parameters). Regardless of the structure of emergent vegetation, we relocated the neonates most often within the leaf litter layer. We observed one neonate in the entrance of a mole burrow, and found another occupying a shallow depression under the leaves. Similar postures, occasionally termed "forms," have been recorded in neonate semi-aquatic turtles (Butler and Graham 1995) and adult *T. carolina* (Flitz 2003; Stickel 1950). In the early part of the activity season (e.g., April), leaf litter might provide some insulation from cool air currents above the leaves or concealment from predators.

Radio telemetry of amphibians and reptiles historically has been constrained by the size and mass of the transmitter. Whether implanted or affixed to the animal's surface, the concern has been that the subject mobility would be impaired by the transmitter's bulk (Fitch 1987; Richards et al. 1994). In spite of losing half of our test animals, we do not think that the LTM transmitters impaired the movements of neonate box turtles. We observed each of the neonates moving within the leaf litter layer without hindrance from the transmitter or its antenna. Transmitters of this size and style would probably be suitable for other small turtle species. Construction of a similar transmitter with a longer battery life would be most useful to better assess microhabitat selection and activity of neonate turtles without undue disturbance.

Our data represent only three individuals of a single *T. carolina* clutch. Nevertheless, they provide information on the activity of a poorly-studied life history stage of a turtle species that is encountered across much of the eastern United States. As the survival of pre-adolescent individuals is essential to ensure the persistence of any species, we hope to encourage further study of early life history stages with the technology that has recently become available and affordable. Furthermore, as neonate turtles might utilize habitat that differs from juvenile and adult areas of activity (Butler and Graham 1995; Dodd 2001), conservation efforts for some turtle populations may be overlooking habitat types that are critical to the species' survival.

Acknowledgments.—We thank C. Forst, W. Jordan, T. Stranz, and M. Wood for their assistance with data collection. N. Foster and T. Tinker of the Boy Scouts of America allowed us access to the study site. Partial funding was provided by Eastern Illinois University. Comments from C. Foster, W. Jordan, S. Klueh, J. Towey, L. Walston, and two anonymous reviews improved an earlier draft of this manuscript.

Gymnophthalmids are small-bodied lizards (SVL up to 10 cm) that inhabit the leaflitter of tropical and subtropical forests and herbaceous vegetation of open formations from southern Central America to Argentina and some islands of the Caribbean (Ávila-Pires 1995; Pellegrino et al. 2001; Vitt and Zani 1996). They eat insects and other small invertebrates and are oviparous, typically laying a clutch of two eggs (Pellegrino et al. 2001; Vitt 1982).

Ecpleopus is a monotypic genus endemic to the Atlantic rainforest of southeastern Brazil (Peters et al. 1986). The diets of several gymnophthalmids from various regions of Brazilian Amazonian have been reported (Caldwell and Vitt 1999; Colli et al. 1998; Rocha 1991; Vitt 1991, 1995; Vitt and Caldwell 1994; Vitt and Carvalho 1995; Vitt and Zani, 1998; Vitt et al. 1998a,b). However, *Ecpleopus gaudichaudii* is poorly known, in fact no data are available on any aspect of its biology. Here we report information on the diet of *E. gaudichaudii* based on specimens collected in two Atlantic rainforest sites of southeastern Brazil.

The Estação Ecológica da Universidade Federal de Minas Gerais (EEUFMG) (19°25'S, 43°58'W) is a 102-ha urban-disturbed reserve located at Belo Horizonte, state of Minas Gerais. Fieldwork was conducted sporadically from 1999 to 2001. Specimens were captured in five, 20-L pitfall traps provided with drift fences in secondary growth forest.

The Reserva Particular do Patrimônio Natural Feliciano Miguel Abdala (RFMA) (19°43'53"S, 41°49'00"W) is a fragment of Atlantic forest located in the city of Caratinga of southeastern Minas Gerais. Fieldwork was conducted from July 2000 through July 2001 by JC. Specimens were obtained by a combination of opportunistic collection, targeted visual searching, and 20-L pitfall traps, which were monitored from December 2000 to April 2001.

Preserved lizards were dissected and their stomach contents were analyzed under stereosmicroscope (10–40x). Food items were determined to order or family. The snout-vent length (SVL) of the lizards was measured with a vernier caliper to the nearest 0.1 mm. Similarity of prey utilization among the two populations was estimated with the symmetric niche overlap coefficient (Pianka 1986): $O_{ij} = \sum p_{ij} p_{ik} / (\sum p_{ij}^2 \sum p_{ik}^2)^{-2}$, where *i* is the resource category, *p* is the proportion of resource category *i* and, in this case, *j* and *k* represent the two populations. Voucher specimens of the lizards were deposited in the herpetological collection of the Universidade Federal de Minas Gerais (UFMG 323, 796, 810, 870, 987, 1094–1105).

At EEUFMG, we collected five individuals in a secondary growth forest and at RFMA we collected 12 individuals in areas of primary forest. At RFMA one individual was observed active at night, two individuals were found active by day, three individuals were found under logs by day, and the remaining specimens were captured in the pitfall traps.

Mean SVL of the lizards was 31.5 ± 4.7 mm (N = 11). The diet was numerically dominated by termites (32.6%) and spiders (18.3%) (Table 1). More frequent items in the stomachs (N = 17) were spiders (0.36), orthopterans (0.24), and isopods (0.24). The stomachs of six individuals (35.3%) were empty. The diet differed in the two areas ($O = 0.11$).

Ecpleopus gaudichaudii seems to be a diet generalist, like other gymnophthalmids (e.g., *Neusticurus ecpleopus* and *Prionodactylus eigenmanni*, Vitt et al. 1998a,b). It is not clear if the apparent differences in prey between these sites reflect differences in prey choice, availability, or the small number of individuals examined.

TABLE 1. Diet summaries for two populations of the gymnophthalmid lizard *Ecpleopus gaudichaudii* from the Atlantic forest of southeastern Brazil. EEUFMG = Estação Ecológica da Universidade Federal de Minas Gerais; RFMA = Reserva Particular do Patrimônio Natural Feliciano Miguel Abdala.

Prey Type	EEUFMG		RFMA		Total		Frequency
	N	%	N	%	N	%	(N = 17)
Araneae	—	—	1	3.1	1	2.2	0.06
Salticidae	—	—	1	3.1	1	2.2	0.06
Scytopidae	1	7.1	—	—	1	2.2	0.06
Theridiidae	—	—	7	21.9	7	11.7	0.18
Opiliones	1	7.1	1	3.1	2	4.4	0.12
Collembola	1	7.1	—	—	1	2.2	0.06
Dictyoptera	—	—	1	3.1	1	2.2	0.06
Diptera	—	—	1	3.1	1	2.2	0.06
Hemiptera	1	7.1	—	—	1	2.2	0.06

Psocoptera (Psocidae)	2	14.6	—	—	2	4.4	0.06
Isopoda	3	21.4	2	6.2	5	11.0	0.24
Totals	14	100	32	100	46	100	

The higher proportion of sedentary prey in the diet of *E. gaudichaudii* supports the idea that active foragers feed primarily on small, clumped prey (Colli et al. 1997; Huey and Pianka 1981). At the taxonomic level of the prey reported here, the diet of *E. gaudichaudii* is similar to that of the closely related cercosaurine gymnophthalmids (Pellegrino et al. 2001) *Neusticurus ecpleopus* (Rocha 1991; Vitt et al. 1998a) and *Prionodactylus eigenmanni* (Vitt et al. 1998b), and the gymnophthalmine *Vanzosaura rubricauda* (Vitt 1995).

The elongate and streamline body and tail of *E. gaudichaudii*, together with its relatively narrow mouth and the presence of a chemosensory-sensitive tongue, are suggestive of an active forager (Colli et al. 1997; Cooper 1994). However, we are not able to define the activity period of *E. gaudichaudii* because of the three individuals found active, two were apparently active by day and the other at night.

Acknowledgments.—We thank A. Kumagai and E. Machado for insect and spider identification, respectively. We especially thank E. Veado for permits to conduct this research in RFMA and K. Stryer for facilities. J. Gomes and R. Ribeiro helped to collect some of the lizards in RFMA. M. Marcos provided climatic data. F. Cruz, R. Espinoza, and an anonymous referee made valuable comments on the manuscript.

Cajun-French Common Names for Louisiana Amphibians and Reptiles

CLIFFORD L. FONTENOT, JR.
Department of Biological Sciences, Southeastern Louisiana University Hammond, Louisiana 70402, USA
e-mail: cfontenot@selu.edu

The use of common names for organisms has long plagued biologists and others because there are often multiple names for the same species or similar names for different species. This problem certainly exists for amphibians and reptiles, and efforts sanctioned by the Society for the Study of Amphibians and Reptiles, the American Society of Ichthyologists and Herpetologists, and The Herpetologists' League, have resulted in a list of standardized English common names. Many previous authors were instrumental in laying the groundwork for this list (Crother et al. 2000, and references therein). However, some areas of North America have an extensive cultural history that has resulted in a unique and widespread collection of local common names. Because of the heavy French influence that has persisted in southern Louisiana at least since the 1700s, there is a collection of Cajun-French common names used ubiquitously throughout southern Louisiana, particularly within the Acadian Parishes. Given that many species of amphibians and reptiles in southern Louisiana are known locally by different names than the standard list for North America (Crother et al. 2000), it would seem useful to have a parallel list of Cajun-French names for southern Louisiana. I have compiled such a list below, primarily to facilitate fieldwork and communication about these species with local people, but also to document a unique set of common names represented by a unique local culture. Such documentation also serves as a resource for interpreting these common names as they have often appeared in the herpetological literature. This list is not exhaustive, as not every species in the area has a French common name applied. The names given here are from the "prairie" dialect spoken in the Ville Platte/Opelousas area, and there may be some variation among other areas of the Acadian Parishes. This list is also not intended to replace any of the existing Standard English names, but rather, to serve as a complement to those names. The Standard English Name according to Crother et al. (2000) is presented first, followed by the Cajun-French name, with an English translation or explanation in parentheses.

Cajun-French Common Names for Louisiana Amphibians and Reptiles

FROGS – Grenouilles (frogs)

American Bullfrog (*Rana catesbeiana)* – Ouaouaron (the name mimics the male's call)

Treefrogs (*Hyla*) – Rainette (little rain frog)

Chorus Frogs (*Pseudacris*) - Rain Frogs (refers to their activity association with rain)

Toads (*Bufo*) – Crapauds (toads)

SALAMANDERS

Three-toed Amphiuma (*Amphiuma tridactylum*) – Anguille (eel), Congre (refers to Congo Eel)

CROCODILIANS

American Alligator (*Alligator mississippiensis*) – Cocodrie (likely derived as a variation of the French pronunciation of crocodile)

American Crocodile (*Crocodylus acutus*)– Crocodile

LIZARDS – lizards (lizards)

Little Brown Skink (*Scincella lateralis*) – Chien de Terre (ground dog), Soudèe

SNAKES – Serpents (snakes)

Copperhead (*Agkistrodon contortrix*) – Sonnette de Canne (cane rattler; shaking the tail against sugar cane leaves produces the sound of a rattlesnake)

Cottonmouth (*Agkistrodon piscivorous*) – Serpent Congo (Congo snake)

Timber Rattlesnake (*Crotalus horridus*) – Serpent *à* Sonnette (rattle snake)

North American Watersnakes (*Nerodia*) – Serpent d'Eau (water snake)

North American Gartersnakes (*Thamnophis*) – Serpent d'Arbre (tree snake, referring primarily to *T. proximus*)

DeKay's Brownsnake (*Storeria dekayi*) – Vipère (also called ground rattler in English, both of which are probably derived by misidentification, referring originally to the Pygmy Rattlesnake (*Sistrurus*))

Texas Ratsnake (*Elaphe obsoleta*) – Serpent *à* Rat (rat snake), Serpent *à* Z-oeufs (egg-eating snake)

Rough Greensnake (*Opheodrys aestivus*) – Couleuvre (snake)

Common Kingsnake (*Lampropeltis getula*) – Serpent Roi (king snake)

Eastern Racer (*Coluber constrictor*) – Serpent Noir (black snake), Fouetteuse (whipping snake)

Red-bellied Mudsnake (*Farancia abacura*) – Pointe, Aspique, Aspic (ice pick, referring to pointed tail)

TURTLES – Tortues (turtle)

Alligator Snapping Turtle *(Macrochelys temminckii*) – Trois rangs (Three-Row), Caouane (tortoise/turtle)

Common Snapper (*Chelydra serpentina*) – Cailleux (rough, ugly skin), Caouane

North American Softshells (*Apalone* sp.) – Caille molle (soft shell), Caouane de Mer (slough turtle)

Pond Slider (*Trachemys scripta*) – Tête Verte (green head)

Mobile Cooter (*Pseudemys concinna mobiliensis*) - Mobilien

All other sliders (*Trachemys*), Cooters (*Pseudemys*), Map Turtles (*Graptemys*) - Ventre Jaune (yellow belly)

Razor-backed Musk Turtle (*Sternotherus carinatus*) – Caouane de Saule (willow turtle)

Stinkpot (*Sternotherus odorata*) – Caouane Puante (stinking turtle)

Eastern Box turtle (*Terrapene carolina*) – Caouane de Rosée (dew turtle)

Acknowledgments.—The field knowledge of June Sylvester, Dean Sylvester, and Clifford Fontenot, Sr., was critical to the production of this list, as they contributed or corroborated many of the entries. For comments on the manuscript, I thank Barry Ancelet, Brian Crother, and Ernie Liner.

Human fear and dislike of snakes has been extensively studied and publicized (Cavendish 1994; Morgan 1996; Morris and Morris 1965). Indeed, the persecution of snakes by humans, both in the past and present, is one reason that many snake species and populations now are threatened (Greene 1997). Public opinion often influences the effectiveness of conservation initiatives; therefore, influencing and educating the public is seen as one way that managers can ensure that their decisions are respected, implemented and maintained (Jacobson 1995). Altering public opinions towards snakes will be particularly challenging because of the widespread animosity and fear shown towards these animals.

Well-conducted interpretive programs generally are considered an important mechanism for shifting public opinion. Many professionals and amateurs spend countless hours delivering interpretive programs on animals such as snakes. Many of these programs target children, who often display a pronounced dislike towards snakes similar to that shown by adults. Positively influencing children's attitudes towards snakes today is seen as a proactive step towards future snake conservation initiatives. Surveys collected by ourselves and others consistently place snakes

among children's most feared animals (see Table 1). Furthermore, previous work has indicated that it is between the ages of 4 and 9 that children tend to develop fears, affections or other emotional concerns towards certain animals (Kellert 1985; Ost 1987). This age bracket also represents that time when children are first able to start perceiving the concept of endangered species (Hungerford 1996).

Because of the time, effort and cost invested in interpretive work, it is crucial to determine the effectiveness of such programs. Carlson (1995) cautions that interpreters should not simply rely on intuition to confirm that their message has been effectively transmitted, and many studies have been conducted to analyze the effectiveness of interpretive programs (Barrie and Knapp 1998; Beckmann 1999; Morgan 1989; Morgan et al. 1997). To this end, we conducted an experiment to address two important questions: (1) Does the delivery of one short, informative and interactive presentation to children affect their attitudes towards snakes, and (2) if a change in attitude is observed, how long does it last?

We conducted this study using Grade 2 public-school classes in Kamloops, British Columbia, Canada, during the 2001–2002 academic year. We designed an instrument for assessing attitudes towards snakes (following Alreck and Settle 1995 and Henerson et al. 1987). This instrument consisted of a series of questions concerning snakes, followed by a series of faces depicting a range of emotions (Fig. 1). The children were asked to respond by circling the face below the appropriate adverb that best reflected their feelings in response to each question. Student responses were ranked from 1 to 5, with 5 representing the most positive attitude and 1 the least positive attitude. In addition to separately analyzing the responses to each question, we generated a grand mean attitude score. This score represented the students' overall attitude towards snakes (Henerson et al. 1987). Several other general questions were asked, including a request for students to list their most feared animals (see Table 1). In order to verify that our assessment instrument was indeed measuring children's attitudes towards snakes, we ensured the instrument had face validity (Henerson et al. 1987).

Eight Control classes of students were involved in this study, along with six 'Presentation' classes that received a snake-interpretive talk (overall mean = 17 students/class, SD = 5.9). The Control classes received a total of three attitude assessments: an initial assessment, followed by a second assessment one week later, and a third and final assessment two months later. The Presentation classes completed the same attitude assessment instrument a total of four times: one day before the snake-interpretive talk, followed by three more assessments occurring one day, one week, and two months after the talk. In order to participate in this study, all students were required to submit signed parental consent forms. We initially were concerned that this provision would significantly bias the composition of students allowed to attend the snake presentations; although we were unable to determine precisely how many children were not allowed to participate, we estimate it was quite small, constituting no more than 5% of the total student body, and never exceeding more than one student per class.

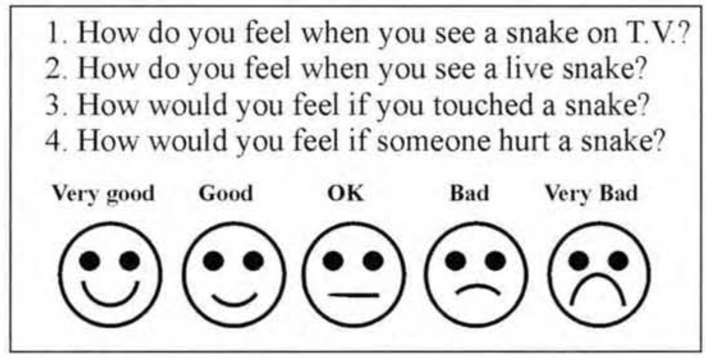

FIG. 1. Attitude assessment instrument consisting of four core questions and the semantic differential scale used to quantify the childrens' reactions. Students were asked to circle the face that best represented how each snake-related question made them feel. Student responses were ranked from 1 to 5, with 5 representing the most positive attitude and 1 the least positive attitude.

The classroom presentations consisted of 20-minute, interactive talks delivered by the senior author. Our previous experiences, coupled with feedback from teachers during pilot presentations, were used to design the presentation at a level suitable for Grade 2 children. Because presentations that incorporate modeling and provide direct contact opportunities can be more effective at influencing attitudes (Morgan 1996), we supplemented our factual information with the opportunity to touch local, non-venomous snake specimens (live Rubber Boa [*Charina bottae*] and Gopher Snake [*Pituophis catenifer catenifer*]). These contact opportunities were brief as students were allowed to touch the snakes with only one finger for a few seconds. Reluctant individuals were not pressured to participate in the contact, as other research has shown that in order for an interpreter's message to be conveyed effectively, individuals must want to touch the snake and must feel in control of the situation (Carlson 1995).

These presentations were followed by a maximum 10-minute question period, where students were allowed to inquire about anything related to snakes; however, storytelling was discouraged. All teachers agreed not to incorporate any snake, reptile, or related units into their class's curriculum during the academic year of the study in order to eliminate this potential source of bias. Furthermore, Presentation classes were not intentionally made aware of the forthcoming 'snake talk' during the first assessment period; however, because advance parental consent forms were mandatory, there is the possibility that some students had been informed of the upcoming event by their parents. We used Pearson's *r* test for reliability because the identical assessment was delivered

TABLE 1. Comparison of the top three animals feared by schoolchildren from: Kamloops, Canada (this study); Victoria, Canada (Bowd 1983); Australia (Bowd 1984); and British Isles (Morris and Morris 1965).

Location	Age	N	Top 3 Feared Animals (% of total response)
Kamloops, Canada	6–8	152	Bear (14), Lion (12), Snake (10)
Victoria, Canada	5	37	Bear (18), Tiger (12), Snake (12)
Australia	10	104	Snake (43), Lion (26), Spider (19)
British Isles	4–14	11,960	Snake (27), Spider (9), Crocodile (4)

to the same individuals multiple times. The results of these tests indicated that the instrument was reliable, displaying a weak to moderate correlation between responses obtained from repeated application of the assessment instrument to the Control classes (all $rs > 0.51$, all $Ps < 0.001$).

Our initial results showed surprisingly high positive mean-attitude scores towards snakes (Fig. 2), despite the fact that numerous students also cited snakes as one of their most feared animals (see Table 1). Although improvement might be difficult if the audience already tends towards a positive attitude (Morgan 1997), the Presentation classes still showed a significant increase in their attitude scores immediately after the snake-interpretive talk ($t_5 = 2.62$, $P = 0.05$; Fig. 2). However, results from the post-attitude assessments indicated that attitudes had returned to pre-presentation levels over the course of only one week, and remained there up to the final two-month assessment period. The effects of time, treatment, and their interaction on the students' attitudes towards snakes all were insignificant (MANOVA, all $Ps \geq 0.17$). Repeated-measures ANOVA was used to compare the responses to each individual question between assessments. Only one of the four attitude questions ("How would you feel if you touched a snake?") elicited a significant positive attitude change that was maintained up until one week after the presentation ($F_{1,1} = 5.27$, $P = 0.02$; all other P values > 0.1). After two months, this change was still evident, albeit weaker ($F_{1,1} = 3.54$, $P = 0.06$).

It is interesting that the only question to which attitudes remained significantly altered was the one that referred to actually touching a snake, rather than just visualizing it. Some studies have found that including a hands-on component in programs directed at improving attitudes towards snakes can actually have negative impacts (Morgan 1996). Students without previous hands-on snake experience would have had to generate an attitude towards touching snakes without ever having done so. Unfortunately, we did not collect data on previous snake encounters and so cannot examine the effects of these encounters on the children's attitudes. After receiving our snake-interpretive talk, these students would have been able to base their attitudes towards touching snakes on a direct, hands-on experience. Although this positive attitude change did not influence the students' over-all attitudes towards snakes, it still may have helped shape their 'mental picture' of them (Meredith et al. 1995). It is this internal "picture" made-up of the students' past experiences, thoughts and feelings that must be influenced before attitudes towards seeing these reptiles can be changed.

As noted, the senior author conducted all of the interpretive talks in order to standardize the experiment. The effectiveness of interpretive talks likely will vary depending on the presenter's ability to effectively communicate information. However, during informal discussions with the teachers following our talks, all of them indicated they believed the talks were conducted at a level appropriate for educating (and entertaining) Grade 2 children. The attitude assessment instrument is another potential source of variability that should be considered in future studies. Because of the short time frame imposed on this study, face validity was the most feasible method for measuring the strength of our attitude assessment instrument. Time permitting, it would be in the best interest of future researchers to conduct a more thorough analysis of the assessment instrument in order to enhance its credibility (Henerson et al. 1987).

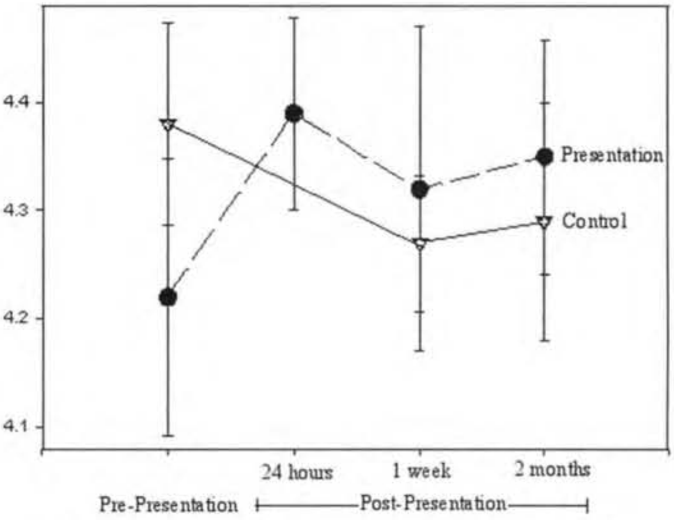

FIG. 2. Grand mean attitude scores in relation to presentation date of Presentation and Control grade two classes (N = 14) from school district #73 in Kamloops, British Columbia. An attitude score simply refers to the students' general feelings towards snakes. A score of five reflects a most positive attitude, while a score of one reflects a most negative attitude. Here, each point represents the mean of all class average attitude scores. Those students that received the presentation (Presentation students) adopted, on average, a more positive attitude towards snakes immediately after the presentation occurred.

Previous studies show that interpretive programs can be effective at influencing children's attitudes towards snakes, at least in the short term (Morgan 1996). In our study, these changes appeared to decline somewhere between 1 and 7 days after the interpretive talk. Without some quantification of the long-term influence of such presentations, this failure to induce permanent attitude changes in the audience (the students) would have gone undetected. Based on our results, we caution interpreters and educators that snake presentations, similar to those conducted in our study, should not automatically be assumed to cause a permanent improvement in the attitude of young children towards snakes. At the same time, our results should not deter the implementation of snake-interpretive programs, or those based on any other animal, as a large amount of in-school animal education is completely devoid of direct contact opportunities (Kellert 1985). Instead, we argue that further study on the effectiveness of snake interpretive work is imperative, particularly so that maximum gains can be made from the efforts of those involved. For instance, periodically revisiting the "snake topic" with the audience (the students) might be required to maintain long-term, positive attitudes towards snakes. In fact, extensive research opportunities exist for those determined to influence public perception of snakes; we urge biologists with an interest in snakes and other maligned animals to consider bridging out into this critical component of conservation.

Acknowledgments.—Authorization to conduct this research was granted by the University College of the Cariboo Ethics Committee for Research and Other Studies Involving Human Subjects. We thank Bill Gilroy for assisting with the preliminary study design layout and for providing critical background information. Our study was made possible through the participation of the Kamloops/Thompson School District #73; we are particularly grateful to the teachers and students who partook in this study.

e-mail: fecastaneda@yahoo.com

We collected from 2–6 September 2003 in the Cerro Texíguat Wildlife Refuge (15°25'49"N, 87°18'32"W), northern Yoro, Honduras, in the vicinity of the type localities for two species of snakes (*Geophis damiani* Wilson, McCranie, and Williams, 1998, and *Rhadinaea tolpanorum* Holm and Cruz D., 1994). Both of these species were known only from their holotypes until we collected the second specimens of each. We herein provide information on variation in scalation, tail length, and color pattern based on these new specimens.

The second specimen of *Geophis damiani* (USNM 559598) is an adult female (total length 303 mm) that agrees in most details with the adult male holotype. Variation in scutellational features is as follows (data for the holotype in parentheses): ventrals 143 (136); subcaudals 34 (41); and temporals 0+1–0+2 (0+1). The tail length is 15.5% of the total length (18.3%). Color in life was similar to that of the holotype. The new specimen was crawling in leaf litter in moderately disturbed cloud forest at 1950 h (about 1 h after dark) and 1680 m elevation.

The second specimen of *Rhadinaea tolpanorum* (USNM 559600) is an adult female (total length 419 mm) that agrees in most features with the adult female holotype. Variation in scutellational features is as follows (data for the holotype in parentheses): ventrals 157 (164); subcaudals 73 (68); and infralabials 8–7 (8–8). The tail length is 26.0% of the total length (25.7%). Color in life was also similar in most details to that provided for the holotype by Holm and Cruz D. (1994), differing only in that the narrow vertebral dark stripe in the new specimen is present only anteriorly and posteriorly on the body and the pale stripe above the dark dorsolateral stripe is only slightly paler than the remaining dorsal color (shown to be white in the holotype in these authors' Fig. 2). The second specimen was crawling on the ground at 1140 h and 1690 m elevation in second growth forest with low vegetation (ca. 1.5 m high) associated with a landslide. The weather was clear and sunny at the time of capture.

Acknowledgments.—Collecting and exportation permits were issued by C. González, M. Moreno, and H. Portillo of COHDEFOR, Tegucigalpa. The G. Enamorado family of San Francisco, Yoro, provided transportation to and from the collecting locality. Other transportation was provided by F. D. Castañeda. An early draft of the manuscript was read by L. D. Wilson.

Observations of Boreal Toad (*Bufo boreas*) Breeding Populations in Northwestern Utah

PAUL D. THOMPSON
Utah Division of Wildlife Resources, 515 East 5300 South
Ogden, Utah 84405, USA
e-mail: paulthompson@utah.gov

From 1999 to 2003, the Utah Division of Wildlife Resources studied Boreal Toad (Western Toad; *Bufo boreas*) breeding populations in northwestern Utah. I report several apparently unique characteristics related to movement, elevation, habitat, and timing of breeding.

Six breeding ponds were monitored in the Grouse Creek Mountains, elevation 1690–2070 m, Great Salt Lake Desert Drainage Basin (mean annual precipitation of 23 cm), in Utah (Fig. 1). Boreal Toad breeding occurred in springs which had been dredged and bermed in the 1950s to create small ponds (surface area 30–900 m^2; maximum depth 0.5–2.5 m) for livestock watering. Emergent vegetation was dominated by rushes (*Juncus* spp.), sedges (*Carex* spp.), Hardstem Bullrush (*Scirpus acutus*), Cattail (*Typha latifolia*), and Teasel (*Dipsacus fullonum*). The upland vegetation community was Single-leaf Pinyon (*Pinus monophylla*)-juniper (*Juniperus* spp.)/sagebrush (*Artemisia* spp.).

Visual searching and dipnetting was conducted at breeding sites once a week during a six to eight week period (Thomas et al. 1997). New eggs strands were counted, and if not distinguishable, the minimum number of egg strands was estimated. An egg strand was considered a pair of egg strings in a gelatinous strand, so counts likely approximated the number of clutches. Small, fragmented egg strands were not counted, as these strands were a result of strands that were not continuously deposited. Adults were caught by hand or dip net from breeding aggregations. Passive Integrated Transponder (PIT) tags (10 x 2.1 mm) were used to individually mark toads (Corn et al. 1997; Muths et al. 2003). A small incision was made with sterile scissors horizontal to the mid-dorsal line, a sterilized PIT tag was implanted subcutaneously, and the tag was worked to the posterior of the toad to prevent it from being expelled before the small wound healed. Only *B. boreas* $\geq$ 50 mm snout–vent length were tagged. For two consecutive years per site, population sizes with 95% confidence limits were estimated with the closed captures model from the Program MARK (White and Burnham 1999). This model assumes no births, deaths, immigration, or emigration.

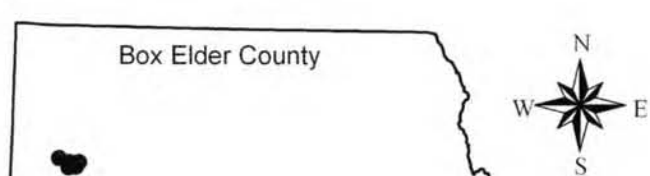

FIG. 1. Locations of six *Bufo boreas* breeding sites monitored in northwestern Utah.

Breeding consistently occurred in late March at two sites and in early May at the remaining four ponds. The earlier sites were fed by 12 and 17ºC warm springs, while the other four breeding ponds were 6–8ºC in early April. Boreal Toads did not breed synchronously; the breeding period ranged from two to six weeks, likely due to variable spring weather, and averaged four weeks per site. Initiation of *B. boreas* breeding appears to be correlated with the onset of warming weather and snowmelt (Blaustein et al. 2001; Blaustein et al. 2003; Campbell 1972; Corn 2003; Corn and Muths 2002; Olson 1988; Olson et al. 1986), however, breeding at the two warm springs was initiated when as much as 0.5 m of snow remained on the ground and the breeding ponds at the other four sites typically were frozen. Boreal Toads remained active year round at one warm spring. A covered spring box kept the water temperature in the box near 15°C during the winter of 2003 and a site visit in January 2003 resulted in the capture of 35 active adult toads.

During the five breeding seasons, tadpoles were observed on three occasions when egg strands had not been detected during prior visits; a minimum of one egg strand was assigned in these cases. Dense emergent vegetation likely hampered detection of egg strands at the two sites where egg strands were missed. During the five-year period, the total number of egg strands observed per year at all six breeding sites ranged from 28 to 45, with the largest number at a single site being 14 (Table 1). Variation among years in egg strand production was observed at all sites. Olson (1991) observed that half of female *B. boreas* skipped one year between breeding and 30% of them skipped 2–3 years, which might explain some of this variation. Another explanation might be loss of breeding habitat, a result of a drought that northwestern Utah experienced during 2000–2003. Sites 4 and 6 experienced an apparent decline in breeding activity (Table 1) and the breeding habitat at these sites was reduced by 50–100% compared to the available habitat in 1999.

PIT-tags were implanted in 981 toads. High recapture rates at breeding ponds indicated that few tags were expelled; 39–84% of the *B. boreas* tagged were encountered on at least one subsequent visit. Population estimates were obtained for two years at five of six sites; a population estimate was not obtained at one site because too few *B. boreas* were captured during that year. Breeding population estimates ranged from 40 to 243 adult toads and, in general, the estimates remained consistent between the two years (Table 2). Although the populations may not have been closed, I feel that little movement occurred at these sites while *B. boreas* were breeding. Toads tended to aggregate 1–2 weeks prior to breeding and tagging was discontinued 1–2 weeks following the last egg strand deposition. In general, sex ratios of breeding adult *B. boreas* were male biased (Table 2), with similar ratios to those

TABLE 1. Number of egg strands per breeding site.

Site	Year 1999	2000	2001	2002	2003
1	12	10	12	8	12
2	5	5	1	5	7
3	3	7	4	4	0
4	6	1	1	0	0
5	5	8	15	11	8
6	14	0	4	5	1
Total	45	31	37	33	28

observed at breeding sites in Oregon (Olson et al. 1986; Olson 1988; Samollow 1980).

Fifteen toads (5 females, 10 males) moved between breeding ponds during the mark-recapture study. The movements were between 0.9 and 5.0 km. Male *B. boreas* are not believed to travel long distances from a breeding site (Loeffler 1998). Muths (2003) and Bartelt (2000) observed post-breeding movements by male *B. boreas* of up to 1 km. I observed two male *B. boreas* that moved longer distances following breeding. One male toad moved 5.0 km between two springs in the summer/fall of 2002 during a severe drought. A wet corridor does not exist between the two springs. This toad was initially tagged in June of 2002 and recaptured in January of 2003 at a warm spring. Another male toad moved 1.3 km between May 2000 and May 2001. In June 2002, this toad was found back at the original breeding locality.

Boreal Toads in the southern Rocky Mountains (New Mexico, Colorado, Utah, southeastern Wyoming, and southeastern Idaho) generally occur above 2500 m in elevation and are restricted to mountain habitats (Hammerson 1999). Campbell (1970) and Livo and Yeakely (1997) describe *B. boreas* populations in Colorado at elevations ranging from 2164 to 3640 m. I found that the population of *B. boreas* in northwestern Utah occupied habitats at considerably lower elevations in a desert environment with pinyon-juniper/sagebrush upland habitats. The six breeding populations in this study were at elevations ranging from 1690 to 2070 m and another breeding location in this region was documented at 1570 m. The lowest elevation of any other known *B. boreas* breeding location in Utah is 2010 m. The dredging and berming habitat alterations in the 1950s may have improved breeding habitat quality for boreal toads in northwestern Utah low elevation areas by increasing water permanency. Continued monitoring of these locations is warranted given their apparently unique characteristics and potential regional instability.

TABLE 2. Population structure of six Boreal Toad breeding populations in northwestern Utah.

Site	Year	Population Estimate	(95% CI)	Standard Error	Sex Ratio (Male/Female)
1	1999	243	(185–347)	40.04	3.8
	2000	110	(102–125)	5.57	2.0
2	1999	141	(126–167)	10.23	4.7
	2000	81	(71–102)	7.61	2.4
3	1999	124	(116–141)	5.97	3.4
	2000	173	(168–183)	3.63	4.0
4	1999	116	(105–137)	7.74	4.1
	2000	N/A		N/A	1.2
5	2001	63	(61–72)	2.40	1.4
	2002	110	(109–116)	1.24	3.1
6	2001	53	(49–63)	3.14	1.6
	2002	40	(39–46)	1.30	1.3

Acknowledgments.—I am especially grateful to Ben K. Nadolski and James S. VanLeeuwen for assisting with fieldwork. The Utah Division of Wildlife Resources funded this project.

Overwintering California Tiger Salamander (*Ambystoma californiense*) Larvae

JEFF A. ALVAREZ
The Wildlife Project, P.O. Box 579805
Modesto, California 95357, USA
e-mail: azoologist@AOL.com

In California, overwintering in larval salamanders is known for three ambystomatid species. Northwestern Salamander (*Ambystoma gracile*) and Long-toed Salamander (*A. macrodactylum*) larvae overwinter in areas where ambient and water temperatures are cold (Stebbins 1985; Stebbins and Cohen 1995; Zug 1993). Introduced Tiger Salamanders (*A. tigrinum*) also may overwinter as larvae (Sexton and Bizer 1978; Riley et al., *in press*). Stebbins and Cohen (1995) and Storer (1925) reported that larvae of a fourth ambystomatid, the California Tiger Salamander (*A. californiense*), do not overwinter; however, B. Shaffer (Univ. California, Davis; pers. comm.) found one larval *A. californiense* in late fall 1993, in Monterey County. I report observations of *A. californiense* larvae overwintering in the Los Vaqueros Watershed, Contra Costa County, California.

Of the 90 managed stock ponds in the Los Vaqueros Watershed, 63 are perennial and 27 seasonal. California tiger salamanders were observed in 66 ponds (45 perennial, 21 seasonal) between 1998 and 2002. Within three perennial stock ponds in the upper Kellogg Creek drainage (eastern Contra Costa County, California), *A. californiese* larvae were recorded through the late fall and winter. On 5 November 1998, a perennial stock pond was drained for maintenance and adult and larval *A. californiese* were found at the bottom of the pond. The three larvae captured ranged in size from 71 to 77 mm SVL, and 125 to 135 mm TL. The pond was located in a heavily grazed grassland at the headwaters of Kellogg Creek (533 m elevation). With the exception of a small stand of cattails (*Typha* sp.), the banks of the pond were devoid of emergent vegetation. Tadpoles of *Rana aurora draytonii* also were observed to be overwintering at this location (Fellers et al. 2001).

During October 1998, a second perennial pond was found with *A. californiense* larvae. The pond was located in an area of grazed annual grassland/oak woodland (300 m elevation) and was devoid of emergent vegetation. Salamanders in this pond were monitored through the winter of 1998/1999. During January 1999, 15 adult and 37 larval salamanders were observed. Larvae ranged in size from 58 to 84 mm SVL, and 114 to 144 mm TL (average = 77.6 mm and 127.3 mm, respectively). Freshly laid eggs also were present in the pond. This pond was monitored weekly until 12 March 1999. During that period, young of the year hatched and developed at a rate that was consistent with other ponds in the watershed.

At a third pond in the Los Vaqueros Watershed (440 m elevation), a single *A. californiense* larva was found in mid-January of 2001. This animal measured 97 mm SVL, 126 mm TL. Again the pond was perennial, associated with cattle grazing, and devoid of emergent vegetation.

Tails tips were collected for genetic analysis from *Ambystoma* larvae overwintering in the Los Vaqueros Watershed. Results confirmed that samples came from *A. californiense* with no detectable level of hybridization (H. B. Shaffer, Univ. California, Davis; 3 genes analyzed: 1 mtDNA, 2 nuclear DNA, 20 specimens, 2 sites, August 2003, pers. comm.).

This report is important because the introduced *A. tigrinum* is being recorded in many areas across California. *Ambystoma tigrinum* is known to overwinter and therefore may be incorrectly identified if the presence of overwintering larvae is the sole characteristic used to determine species. In addition, some authors have suggested that *A. californiense* may not occur regularly in perennial pools (Jennings and Hayes 1994; Storer 1925), yet my findings show 45 of 66 (68%) occupied sites were perennial. Finally, management considerations for perennial ponds may need to be re-evaluated if *A. californiense* larvae are found to overwinter throughout their range. The proper management of *A. californiense* should provide for thoughtful consideration of the implications of overwintering in the species.

Acknowledgments.—I thank the Contra Costa Water District for the opportunity to work with salamanders on their site. H. B. Shaffer provided genetic analysis of salamander tissue samples and comments on the manuscript for which I am very grateful. I thank D. Olson, J. L. Alvarez, and M. A. Shea for useful discussion and comments on the manuscript, and W. K. Weber for assistance in the field and comments on the manuscript.

Understanding of the phenomenon of the squirting of blood from orbital sinuses of horned lizards has been slow in unfolding since its early historic (Spanish Empire 1651 and 1767; Manaster 1997) and scientific reports (Middendorf and Sherbrooke 1992; Wallace 1871). Only infrequently do conditions during capture by humans result in blood squirting. In contrast, this defensive behavior is elicited with much greater frequency by exposure of the lizards to native canid predators such as Coyotes, *Canis latrans* (Sherbrooke and Mason, *in press*) and Kit Foxes, *Vulpes macrotis*; (Sherbrooke and Middendorf 2004), or a Dog (*Canis familiaris*) model (*P. cornutum*: 70–100%, *P. hernandesi*: 50%, and *P. solare*: 60% of trials; Middendorf and Sherbrooke 1992; Sherbrooke and Middendorf 2001). Indeed, this defensive behavior may be elicited by only a subset of would-be predators. For example, *P. cornutum* did not squirt blood in response to a variety of non-canid predators including Greater Roadrunner (*Geococcyx californianus*), Southern Grasshopper Mouse (*Onychomys torridus*), Long-nosed Leopard Lizard (*Gambelia wislizenii*), Western Diamondback Rattlesnake (*Crotalus atrox*), or whipsnakes (*Masticophis* spp.) (Sherbrooke 1990, 1991, 2003, unpubl. data). Anecdotal field observations of human encounters with a specific species of horned lizards can be useful for determining the presence of the behavior if the results are positive, but negative reports leave doubt as to the ability of the species to squirt blood under more appropriate conditions. Nevertheless, negative records under controlled conditions are useful for comparing the relative frequency of occurrence of blood squirting among species.

Recently, field encounters with humans and several species of *Phrynosoma* were combined with controlled encounters with dogs and literature records to identify which of the 13 currently recognized species of horned lizards exhibit antipredator blood-squirting behavior (Sherbrooke and Middendorf 2001). These studies concluded that a clade of three species—*Phrynosoma mcallii*, *P. modestum*, and *P. platyrhinos*—does not use antipredator blood squirting. Individuals of those three species (N = 10–15 for each) failed to squirt blood in controlled trials with a dog as a model canid and had a remarkably low frequency of blood-squirting events in encounters with humans (0.07%, compared to ~5% for *P. solare* and *P. cornutum*; Sherbrooke and Middendorf 2001). The blood-squirting proclivity of several other species in the genus remains in doubt pending tests with appropriate predators or predator models such as dogs. Therefore, Sherbrooke and Middendorf (2001) reported that the propensity to squirt blood in *P. douglasii* and *P. braconnieri* was unknown although expected because of the phylogenetic affinities of the two species with others in the genus that also appear not to squirt blood. Based on reports of human encounters in the literature, these researchers accepted that *P. asio*, *P. coronatum*, *P. orbiculare*, and *P. taurus* squirt blood when approached by predators for which the defense has evolved (i.e., canids). For these species the frequency of these responses in human encounters is unknown, but any positive response to humans apparently indicates the capacity of the species to utilize this defense during encounters with appropriate predators.

Recently one of us (BB) noted that the only literature report of blood squirting in *P. taurus* (Ruthling 1919) was apparently based on a misidentification of the species. Ruthling's (1919) reports of blood squirting for two species of horned lizards, *P. orbiculare* and *P. taurus*, in México were not based on personal observations, but on experiences reportedly made by Carlos Cuesta Terrón, a Mexican herpetologist (see Cuesta Terrón 1932). In recounting Cuesta Terrón's observations, Ruthling (1919) stated that both species were "abundant in the Valley of Mexico." Current information indicates that *P. taurus* does not occur in the Valley of México, where only *P. orbiculare* occurs (Baur and Montanucci 1998; Gonzáles et al. 1996; Sherbrooke 2003; Zamudio and Parra-Olea 2000), bringing into doubt the identification of a species known primarily from Oaxaca, Puebla, and Guerrero (additional reports place *P. taurus* in southeastern Morelos; Castro Franco 1987; Castro-Franco and Busto Zagal 2004). The uncertainty, in 1919, of Ruthling's report stems also from the dubious taxonomic designation and identification of some Mexican species of horned lizards. Cuesta Terrón (1932) failed to mention *P. taurus* in his "Los Camaleones Mexicanos," and Martín del Campo (1934), who included *P. taurus* in his additions, did not mention blood squirting for the species. Therefore, we conclude that Ruthling's report of blood squirting by *P. taurus* is erroneous and should be rejected. This casts doubt on the ability of this species to squirt blood defensively in response to a predator. Here we attempt to resolve this question by presenting data from (1) numerous human field encounters with *P. taurus*, and (2) trials with a dog model of a native canid predator.

Between 1996 and 2003 one of us (EBS) made repeated observations of individuals of *Phrynosoma asio* and *P. taurus* at Cerro Tepelayo, Zumpango del Río, Municipio de Eduardo Neri, Guerrero, México (17°83'09"N, 99°31'31"W; 1280 m). Between 28 March and 16 September there were 35 human field encounters with individual *P. taurus;* of these 7 lizards were males, 21 females, and 7 juveniles. None of the Bull Horned Lizards squirted blood

when captured by hand. Because juvenile *P. cornutum* and *P. hernandesi* squirt blood in response to a dog (Sherbrooke and Middendorf 2001), we expect age is not a critical determinant. Thus, if *P. taurus* has a similar blood-squirting reaction rate to humans as that recorded for Texas horned lizards (*P. cornutum*; 5.9%, Lambert and Ferguson 1985) and Regal Horned Lizards (*P. solare*; 4.6%, Parker 1971), we might predict that 1–2 (~5%) of the 35 *P. taurus* encountered would have squirted blood. However, not all horned lizard species have the same frequency of this defensive behavior when tested with canids (Sherbrooke and Middendorf 2001).

Ten *P. taurus* (9 females, 1 male; mean mass = 15.3 g, range = 8.0–30.5 g; mean SVL = 65.1 mm, range = 53–84 mm) were collected between 18 May and 16 June 2003, and were held in captivity in indoor terraria under natural lighting and fed ants and other insects. Tests for dog-elicited bloodsquirting were conducted on 16 June (N = 9: air temperature 22°C) and 17 June (N = 1; air temperature 26°C) in late afternoon. The dog, a Cocker Spaniel-mix, was held on a leash during the 3-min trials while one of us (WCS) handled the Bull Horned Lizards. During trials, the dog vigorously pawed and barked at the lizards, and in most trials (60%) the dog briefly took the lizard into its mouth, from which it was quickly removed. All lizards repeatedly ran from the dog, but were immediately returned to the study arena. None of the lizards closed their eyelids or engorged them with blood, a precursor to blood squirting (Middendorf and Sherbrooke 1992; Sherbrooke and Middendorf 2001; Sherbrooke and Middendorf 2004), or squirted blood. Immediately following the trials with *P. taurus*, we conducted a single trial with a large (SVL = 110 mm) male *P. asio* (a species known to squirt blood; Alvarez del Toro 1960; Hodges 2004) to confirm the appropriateness of the experimental conditions for eliciting blood squirting. This trial was terminated after 50 s when the horned lizard squirted blood from one orbital sinus onto the dog's muzzle (for comparable times with *P. cornutum*, see Middendorf and Sherbrooke 1992). Both of this lizard's eyelids were engorged with blood prior to squirting.

The negative results with *P. taurus* are similar to those for three other species of horned lizards, *P. mcallii*, *P. modestum*, and *P. platyrhinos* (Sherbrooke and Middendorf 2001). Combined with our negative encounters for blood squirting with humans (N = 35) and those of Hodges (N = 20; Hodges 2004), these data suggest that *P. taurus* either does not squirt or is not easily induced into a blood-squirting defensive behavior. In this sense, *P. taurus* resembles the *P. mcallii-modestum-platyrhinos* clade of "nonsquirting" species of *Phrynosoma* (Sherbrooke and Middendorf 2001). If blood-squirting is not a defensive strategy of *P. taurus*, based on the cladogram presented by Sherbrooke and Middendorf (2001), there may be more than one lineage of *Phrynosoma* that lacks or nearly lacks blood-squirting as a defense response. If *P. taurus* is a nonsquirting species, in contradiction to Ruthling's (1919) report, this calls for reinterpretation (Sherbrooke and Middendorf 2001) of this characteristic in the sister taxon to *P. taurus*, *P. braconnieri* (Hodges and Zamudio 2004).

No published data on blood squirting exist for *P. braconnieri*, but it was suggested that the species might exhibit a blood-squirting defense because of its putative close relationship with *P. taurus* and *P. asio* (Sherbrooke and Middendorf 2001). Recently collected data on blood squirting in *P. braconnieri* suggest that this species may not respond, or displays a reduced frequency of defensive blood squirting (Sherbrooke and Mendoza, *in press*). Thus, there may be two or three clades—*P. douglasii* (Sherbrooke and Middendorf 2001; Zamudio, unpubl. data), *P. mcallii-modestum-platyrhinos* (Sherbrooke and Middendorf 2001), and *P. braconnieri-taurus* (this paper; Sherbrooke and Mendoza, *in press*)—of species in which the frequency of blood squirting is absent or significantly reduced. Although these groupings are interesting, because the phylogenetic relationships among *Phrynosoma* species are not completely resolved (Hodges and Zamudio 2004; Reeder and Montanucci 2001; Zamudio et al. 1997), the determination of the number of times blood squirting has been acquired or lost during the evolution of the genus remains in question.

As was noted with the *P. mcallii-modestum-platyrhinos* clade and *P. douglasii* (Sherbrooke and Middendorf 2001), *P. braconnieri* and *P. taurus* are relatively small bodied. The species best known for blood squirting (*P. asio*, *P. cornutum*, *P. coronatum*, *P. hernandesi*, *P. orbiculare*, and *P. solare*) are the six largest species in the genus (Baur and Montanucci 1998; Sherbrooke 2003). The large robust species *P. asio* seems to have the highest frequency (12%) of blood squirting toward humans (Hodges 2004). This suggests that the size and armament of larger *Phrynosoma* species narrows the range of potential predators to include canids and possibly others, where blood squirting is an effective defense.

Currently there are two methods for determining the blood-squirting response of horned lizards—human encounters and canid trials. Negative results in either case do not prove that a species is incapable of a positive response under other experimental or natural conditions. Even non-*Phrynosoma* iguanian lizards may occasionally exude blood from the orbital sinus, a condition that may have led to the evolution of blood squirting (Sherbrooke 2000). Consequently it is difficult to assign a "nonsquirting" status to a species of horned lizards. Indeed, Sherbrooke and Middendorf (2001) recorded infrequent human-encounter blood squirting within the *P. mcallii-modestum-platyrhinos* "nonsquirting" clade (0.07% of encounters), although the three species did not squirt when tested with dogs. Nevertheless, the dramatic differences in responses among *Phrynosoma* species, to both human and canid predators, suggests that the 13 species in the genus, and perhaps populations thereof, do not employ a blood-squirting defense to the same extent or under the same conditions. Our growing understanding of the circumstances that elicit blood squirting may lead to an appreciation of the selective pressures that fostered its development and diversification of use in species of *Phrynosoma*.

Acknowledgments.—We thank the students from the Universidad Autónoma de Guerrero who assisted with field encounters of *P. taurus* and with collecting horned lizards. We thank the A. Salinas Jardon family for the use of their dog "Carolo." W. Hodges generously provided us with a copy of her unpublished manuscript, and she and K. Zamudio (who reviewed our manuscript) allowed us access to an unpublished manuscript on *Phrynosoma* phylogeny. The American Museum of Natural History IACUC approved procedures involving live lizards.

Dryadophis Versus *Mastigodryas* (Ophidia: Colubridae): A Proposed Solution

JAMES R. DIXON
and
BOB L. TIPTON
Department of Wildlife and Fisheries Sciences, Texas A&M University College Station, Texas 77843, USA

The nomenclatural history of the Neotropical colubrid snake genera *Mastigodryas* and *Dryadophis* is convoluted. The oldest specific name in either of these genera is *Coluber boddaerti* Sentzen, 1796. Fitzinger (1843) assigned the generic name *Eudryas* to *C. boddaerti*. Brongersma (1937) pointed out that *Eudryas* Boisduval, 1836 predated Fitzinger's name. Stuart (1939) proposed *Dryadophis* as a replacement name for all of the species in the group. Dunn (1944), in his report on the amphibians and reptiles of Colombia, suggested that *Mastigodryas danieli* Amaral, 1935a is a synonym of *Dryadophis boddaerti*. Dunn (1944) apparently thought *Dryadophis* was the older name and included *M. danieli* as *Dryadophis* in his discussion (p. 202) of the latter genus. Inadvertently, Dunn's synonymy made *Mastigodryas* the oldest available name for the species recognized in the genus *Dryadophis*. Romer (1956) also suggested that the two genera were congeneric. Smith (1963), prompted by Romer's suggestion, proposed the validation of *Dryadophis* as the accepted name and the suppression of *Mastigodryas* as a senior synonym to the International Code of Zoological Nomenclature (ICZN). Amaral (1964) commented to the ICZN that Smith's request should not be granted because *Mastigodryas* is distinguished from *Dryadophis* by the absence of apical scale pits and a relatively shorter tail in the former. Amaral (1964) concluded that on taxonomic grounds both genera should be recognized. Peters and Orejas-Miranda (1970) placed *Dryadophis* as a synonym of *Mastigodryas* because Peters had examined the holotype of *M. danieli* and concluded that the two genera are not separable. However, Peters did not discuss the characters of *Mastigodryas* presented by Amaral, leaving the subject open for further comment. Smith and Larsen (1973) argued that it was premature to replace *Dryadophis* with *Mastigodryas*, based on Amaral's (1964) comments. Apparently, the aforementioned discussions rekindled the ICZN members to vote on Smith's (1963) proposal. ICZN Opinion 1035 was published in 1975, wherein the commission rejected suppressing the generic name *Mastigodryas*, based on Amaral's (1964) comments.

Between 1935 and 1969 *Mastigodryas* is used as a valid generic name six times, whereas *Dryadophis* was reported in the literature 67 times during nearly the same time frame (1939–1969). The rare use of *Mastigodryas* is likely due to the absence of specimens in collections and/or its recognition as a valid genus.

Despite Peters and Orejas-Miranda's (1970) synonymy of *Dryadophis* with *Mastigodryas*, *Dryadophis* continued to be used as a valid generic name by some herpetologists (Hidalgo 1981; Köhler 1999, 2003; McCoy et al. 1986; Smith and Larsen 1973; Wilson 1979; Wilson and Meyer 1982; Wilson et al. 1976), but others used *Mastigodryas* (Amaral 1976; Boos 2001; Cei 1993; Chippaux 1986; Cunha and Nascimento 1978; de Lema 1994;

Emsley 1977; Giraudo 2001; ICZN Opinion 1975; Murphy 1997; Pérez-Santos and Moreno 1988, 1991; Savage 2002). We approached H. M. Smith (electronic mail) about the possibility of suppressing *Mastigodryas* once again. His comment was

> "The ICZN put the name *Mastigodryas* on the official list of generic names. It did so with the understanding that the genus is different from *Dryadophis* and therefore need not to be suppressed to protect *Dryadophis*. It did nothing with *Dryadophis*, it was not allocated to either the lists (conserved) or indices (suppressed)… had *Dryadophis* been suppressed, there would be no chance of its revival. I think the ICZN nevertheless would never suppress a name already placed on the official list, even though it was placed there on erroneous bases. Furthermore, *Mastigodryas* has been used several decades and appeal for its suppression now in the interest of stability, would be questionable."

In an effort to resolve this long-standing taxonomic controversy, we undertook a study to characterize the variation of *Dryadophis* relative to that found in *Mastigodryas*. In addition to having the holotype of *M. danieli* examined and photographed by Francisco Franco, Curator of Herpetology, Instituto Butantan, we examined four additional specimens of *M. danieli* from Colombia in the collections of the Field Museum of Natural History (FMNH), the Natural History Museum of Los Angeles County (LACM), and the University of Kansas Natural History Museum (KU). We compared the salient features of the genus *Dryadophis* presented by Stuart (1941), with similar characters of five specimens of *M. danieli*. The characters representing the genus *Dryadophis* are presented first, followed by those of *Mastigodryas* in brackets. If the two genera are equal in a particular character, the bracket contains an equal sign. The dorsal scales are smooth [=], in 15–15–15 or 17–17–15 rows [17–17–15] (rows around the body counted 10 ventrals posterior to the gulars, at midbody, and 10 ventrals anterior to the anal plate), with two apical scale pits [=]. The ventrals number 159–206 [171–187], subcaudals 79–136 [71–107], and maxillary teeth 18–26 [19–21]. The supralabials are variable, but usually 8–8 [=]. The infralabials are also variable and usually 10–10 [=]. The preoculars are 1–1 [=], postoculars 2–2 [=], and the loreal 1–1 [=]. Supralabials entering the orbit are 4+5 or 4+5+6 [4+5+6]. The temporals are variable, usually 2+2 [=], and the anal plate is divided [=]. Given these similarities and broadly overlapping characteristics, we recommend that *Mastigodryas* and *Dryadophis* be relegated to the single genus, *Mastigodryas* because of seniority.

A redescription of the holotype of *M. danieli* and other specimens follow. If scales differ on opposite sides of the head, the right side is recorded first. If our data differ from Amaral's (1935a) description, his differences are in italics, and any additional data are in bold print.

The holotype of *M. danieli* (IB 8694) is an adult female with a total length of 895 mm. The tail length is 190 mm (tip possibly missing) and the tail/total length ratio is 0.212. The dorsal scale rows are smooth, and in 17–17–15 rows. Scales contain **two small apical pits** (*none*). Ventrals number 183, with two preventrals (*187*), whereas the subcaudals number 70 (**+tip**?). Supralabials are 9/9, infralabials 11/12, with the fifth and sixth in contact with the anterior chin shields. Preoculars are 1/1, postoculars 2/2, temporals 2+2, and the supralabials entering the orbit are the fourth, fifth and sixth. The loreal is 1/1 and the anal shield is divided. Maxillary teeth are **19/19** and dentary teeth **21/22**. The color has changed after 67 years in preservative. The anterior two thirds of the body is bluish black, whereas the posterior third is brownish blue. There is no indication of a pattern on any part of the body. The ventral surface is bluish black.

The only additional female examined (FMNH 63783) has an incomplete tail and contained five eggs. It differed from the holotype of *M. danieli* in having 177 ventrals, 1+2/2+2 temporals, and 21 maxillary teeth. The three males examined (LACM 72750, 114654; KU 169953) respectively have ventrals numbering 171, 187, 172, and subcaudals, 98, incomplete, 107. The supralabials are 9/9 in all. The infralabials are 10/10, 11/11, 9/9, and the maxillary teeth number 19, 19, 20. The tail length/total length ratios vary from 0.26, —, 0.29. The reduction site of all four individuals occurred with the fusion of scale rows 3 and 4 over ventrals 107/107 for the female, and 89/93, 113/113, 102/— for the males.

The color of these specimens is similar to that of the holotype. The venter is bluish brown with an indistinct white line on the outer margin of the ventrals. The white line is discontinuous from the fifty-seventh ventral to the anal plate in KU 169953. The throat is bluish brown with a few white spots on the chin and throat in all four specimens. The above summarizes the known variation in *Mastigodryas*.

Acknowledgments.—We thank R. Fernandes for arranging the examination of the holotype and F. Franco for his examination of the holotype and the digital photographs. We also thank F. Franco for noting characters that Amaral either did not record or recorded erroneously. We thank R. K. Vaughan for providing one of us laboratory space to examine specimens. We thank the following persons for allowing us to examine specimens in their care: J. Simmons (KU), H. Voris (FMNH), and K. Beaman (LACM). We also thank the anonymous reviewers, L. D. Wilson, and the associate editor for their suggestions and criticism.

Photographic Identification as a Noninvasive Marking Technique for Lacertid Lizards

ANNA PERERA*
and
VALENTÍN PÉREZ-MELLADO
Department of Animal Biology, University of Salamanca
Campus Unamuno, s/n, 37071 Salamanca, Spain
**e-mail: a21279@usal.es*

Color and body patterns have long been used to identify individual lacertid lizards (Schmidt-Loske 1996), but may be unsuitable for long-term studies because they vary with reproductive condition, age, and other factors (Henle et al. 1997). Elbing and Rykena (1996) found that individual *Lacerta viridis* could be recognized by patterns of head scalation, and although these scales do not vary over time (Fox 1975), Elbing and Rykena (1996) considered this method of identifying individuals to be excessively time consuming and, in some cases, difficult to use because of the small size of the scales. Recently, Steinicke et al. (2000) found photographic identification of the scales of the first four rows of ventrals to be a suitable technique for recognizing individuals of five species of lacertids (*Lacerta agilis*, *L. bilineata*, *L. viridis*, *L. vivipara*, and *Podarcis muralis*). Photographic identification of individuals by means of scale patterns is an emergent technique with a promising future, but it is necessary to examine other species before it can be considered suitable for lacertids, and other lizards generally. The method also must be improved to reduce the time required for identification, especially when many individuals are involved in the study.

We tested the suitability of using ventral scalation to identify individual *Lacerta perspicillata* (SVL = 46.8 ± 0.34, range: 40.5–54.0, N = 99; unpubl. data). From November 2000 to May 2001, we collected 53 individuals on Menorca Island, Spain. We toe clipped and took two pictures of each lizard with a digital camera (Sony Mavica®). Digital photographs (resolution 640 x 480 pixels) were enhanced in the laboratory with Microsoft Photo Editor® (brightness, contrast, and conversion from color to black and white) and printed (600 x 300 dpi). Ninety-three recaptures of the 53 toe-clipped lizards were identified from photographs using ventral characters (i.e., scales of the chin and collar area, arrangement of scales in the chest area and of the longitudinal and transverse scale rows of the trunk, Fig. 1) by two observers. Photographic identification of individuals matched identification based on toe clips in 100% of cases. All individuals were easily identified, and no apparent change in scale pattern was noted.

Our method was subsequently used in a capture-recapture study involving the same population later the same year (June–October 2001). Lizards were photographed and individuals were added to a previously assembled reference collection of pictures. Individuals collected in the field were identified via comparison with the reference file. To reduce time spent on identification, the photographic reference file was organized by sex, and then by natural amputations, scale anomalies (e.g., aberrations, asymmetries), and

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 35, Number 1 (March 2004). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: INDIANA: Posey Co: Pike Township (UTM: zone 16 0412376, 4187414, NAD 83), in a permanent bald cypress (*Taxodium distichum*) swamp. 20 March 2004. Rod N. Williams, Brian J. MacGowan, and Mark Pochon. Verified by Ray Semlitsch, Zack Walker, Robert Brodman and Mike Lodato. Field Museum of Natural History (FMNH 262651–652) and Purdue University Department of Forestry and Natural Resources (PUFNR 10032). First verified record for this species in Indiana. The Indiana Department of Natural Resources is considering the conservation status (endangered or special concern) of this species. Twenty-three individuals (22 in breeding condition; see Semlitsch 1985. Oecologia 65:305–313) were caught on 24 March 2004. Morphological measurements were taken on all individuals and data are available from the authors upon request.

Submitted by **ROD N. WILLIAMS** (e-mail: horse@purdue.edu) and **BRIAN J. MacGOWAN,** Department of Forestry and Natural Resources, Purdue University, West Lafayette, Indiana 47907, USA (e-mail: macgowan@purdue.edu).

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: ALABAMA: Macon Co.: Beaver pond in Tuskegee National Forest (32.4305°N, 85.6470°W [WGS84/NAD83]) 10 June 2004. Verified by Robert Mount, George Folkerts, and Craig Guyer. Auburn Museum of Natural History, AUM 36393. First county record. This record represents a range extension of ca. 150 km and is the easternmost locality for the species (Mount 1996. The Amphibians and Reptiles of Alabama. University of Alabama Press. xi + 347 pp.). Specimen (a male) was found dead at ca. 2200 h lying outstretched on mud under *Juncus* sp. and *Numphar lutea*, less than 30 cm from the water's edge. The water level in the pond had dropped steadily over the previous weeks. Two injuries on the dorsal surface of the head and tail could not be attributed to a specific predator (i.e., no tooth or claw marks) nor were predator tracks visible in the mud. They could be the result of male-male aggression (Cagle 1948. Ecology 29:479–491). Condition of the specimen indicated that it had not been out of the water long; however fire ants (*Solenopsis invicta*) had begun feeding on the carcass and could also have caused the injuries observed. Our record suggests that *A. tridactylum* is widespread throughout the Mobile Drainage and is similar in distribution to the Diamond-backed Watersnake (*Nerodia rhombifer*) and the Southern Painted Turtle (*Chrysemys picta dorsalis*), two species that also prefer similar shallow, sluggish, vegetated aquatic habitats. Additional surveys for this species within the Alabama and Tallapoosa Rivers are needed to confirm this distribution.

Submitted by **ROGER D. BIRKHEAD, VALERIE M. JOHNSON, SCOTT M. BOBACK**, and **MICHELLE L. BOBACK**, Department of Biological Sciences, Auburn University, Alabama 36849-5414, USA; e-mail: birkhrd@auburn.edu.

BOLITOGLOSSA RUFESCENS (Northern Banana Salamander). MÉXICO: QUINTANA ROO: Municipality of Felipe Carrillo Puerto, 17 km SE of Andrés (19°08'51.3"N, 88°02'24.7"W). 12 February 2003. Alejandro Franco. Colección Herpetológica, Museo de Zoología, El Colegio de la Frontera Sur, Unida Chetumal, Quintana Roo (ECO-CH-H-2022). Verified by Luis Canseco and Oscar Flores-Villela. First record for Quintana Roo and a ca. 300 km range extension from the closest previous record in the Cockscomb Basin Jaguar Preserve, Stann Creek, Belize (Lee 1996. The Amphibians and Reptiles from the Yucatan Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.). The specimen was found in a dead tree in secondary, semi-deciduous forest.

Submitted by **RENE CALDERON-MANDUJANO, ALEJANDRO FRANCO,** and **MARISOL MEDINA**, Museo de Zoología, El Colegio de la Frontera Sur, Unidad Chetumal. A.P. 424. C.P. 77059, Chetumal, Quintana Roo, México; e-mail: rcalderon@ecosur-qroo.mx

ENSATINA ESCHSCHOLTZII ESCHSCHOLTZII (Monterey Ensatina). MÉXICO: BAJA CALIFORNIA: Ejido Antonio Meléndrez, ca. 22 km S of Ensenada (31°38.990'N, 116°33.279'W), 371 m elev. 9 February 2003 and 15 February 2004. Francisco Casillas-Figueroa and Anny Peralta-García and Jorge H. Valdez-Villavicencio, respectively. Herpetological collection of Facultad de Ciencias, Universidad Autónoma de Baja California (UABC 1138–39). Verified by Bradford D. Hollingsworth.

Southernmost locality for the species on the Baja California Peninsula and extends the range 58 km S from La Misión (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands, and the Islands in the Sea of Cortés, Univ. of California Press, Berkeley and Los Angeles, California. xiii + 399 pp.). The two specimens were collected during the day in a canyon on the north facing slope of Cerro Buenavista, in chaparral, including ferns and mosses; UABC 1138 was found dead in a pond and UABC 1139 was found alive under a small rock at 1150 h.

Submitted by **ANNY PERALTA-GARCÍA** and **JORGE H. VALDEZ-VILLAVICENCIO**, Facultad de Ciencias, Universidad Autónoma de Baja California, Km. 103 Carretera Tijuana-Ensenada, A.P. 1653, C.P. 22800, Ensenada, B.C., México; e-mail: j_h_valdez@yahoo.com.mx.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: ALABAMA: Cleburne Co: Talladega National Forest, Shoal Creek Ranger District, Dugger Mountain, 6.4 km SSE Piedmont (35°52'02.1"N, 85°33'58.8"W). 24 February 2004. Jeffrey L. Gardner and Eric C. Soehren. Verified by Craig Guyer. Auburn University Museum, Alabama Herpetological Atlas Project database (AHAP-D-0001a–d [digital photographs]). One adult specimen captured while swimming on surface of vernal pond within Dugger Mountain Wilderness Area; photographed and released. New county record. (Mount 1975, Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University. 347 pp.).

Submitted by **JEFFREY L. GARDNER**, Shoal Creek Ranger District, Talladega National Forest, 2309 Hwy 46, Heflin, Ala-

bama 36264, USA, and **ERIC C. SOEHREN**, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 North Union Street, Montgomery, Alabama 36130, USA; e-mail: jeffgardner@fs.fed.us.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: TENNESSEE: HICKMAN CO.: Just W of Carothers Cemetery, ca 2.0 air mi W of Grinders Switch (35°47'40"N,87°30'36"W). 03 April 2004. David Anderson. Austin Peay State University Museum of Zoology (APSU 17499, 2 color photos). Verified by A. Floyd Scott. One adult observed under rotting pine log in forested area. New county record in Duck River drainage (Redmond and Scott. 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, Center for Field Biology, Austin Peay State University, Clarksville, Tennessee and web version at http://www.apsu.edu/amatlas/ which includes links to information on records published since 1996; accessed 4 June 2004).

Submitted by **DAVID ANDERSON**, 1150 Riverview Road, Centerville, Tennessee 37033, USA; e-mail: dandm5@bellsouth.net.

ANURA

BUFO CALIFORNICUS (California Arroyo Toad). MEXICO: BAJA CALIFORNIA NORTE: Rio Santo Tomas, 16 air km E Santo Tomas near Rancho Las Aguillas (31.54913°N, 116.22174°W), 400 m elev., 26 May 2004. Los Angeles County Museum of Natural History voucher photograph (LACM-PC 1400). Observed by Robert Lovich, Barry Downer, and Clark Mahrdt. Photos verified by Edward L. Ervin. This species is distributed disjunctly in several river drainages west from the Sierra Juarez and Sierra San Pedro Martir peninsular range to the foothills and coastal drainages south to San Quintin in northwestern Baja California (see Mahrdt et al. 2002. Herpetol. Rev. 33:123–125; Mahrdt et al. 2003. Herpetol. Rev. 34:256–257). Three juvenile and three adult *Bufo californicus* were observed in sparse oak woodland and riparian habitat on sandy soil substrate. The Rio Santo Tomas record fills a 40 km gap between the Rio Zorrillo and Rio San Vicente and represents a new river drainage for *B. californicus* in Baja California.

Submitted by **CLARK R. MAHRDT**, Herpetology Department, San Diego Natural History Museum, P.O. Box 1390, San Diego, California 92112, USA and **ROBERT E. LOVICH**, AC/S Environmental Security, Box 555008, Marine Corps Base, Camp Pendleton, California 92055-5008, USA.

COCHRANELLA ROSADA. COLOMBIA: ANTIOQUIA: Anorí municipality: Chaquiral forest (6°58'44.3"N, 75°7'53.0"W) 1750 m elev. 14 February 2003. S. P. Galeano and J. C. Urbina. Museo de Herpetología Universidad de Antioquia, Medellín, Colombia (MHUA 2474). Adult male found on the leaf litter at the edge of a stream in the forest. Verified by J. D. Lynch. First department record. Previously known only from Samaná and Pensilvania municipalities of Caldas, Colombia (Ruiz and Lynch 1997. Rev. Acad. Colomb. Cienc. 21[81]:541–553). This record extends the known distribution in 184 km NW from Samaná, and 187 km N from Pensilvania including the northern part of the Colombian Central Mountain.

Submitted by **SANDRA P. GALEANO** (e-mail spgaleano@yahoo.com) and **JENNY C. URBINA**, Instituto de Biología, Universidad de Antioquia, AA. 1226 Medellín, Colombia; e-mail jennyurbina@yahoo.com.

CYCLORAMPHUS MIGUELI (Miguel's Button Frog). BRAZIL: BAHIA: Uruçuca Municipality (14°33'45"S, 39°18'45"W). 06 April 2002. M. Dixo. Museu de Zoologia da Universidade de São Paulo, São Paulo, Brazil (MZUSP 128254–255). Verified by M. Trefaut Rodrigues. Species previously known only from the type locality, Fazenda Unacau, São José da Vitória Municipality, Bahia, Brazil (15°09'S, 39°18'W) (Heyer 1988. Proc. Biol. Soc. Washington 101:151). This new record extends range 66.4 km northward from the type locality.

Submitted by **MARIANNA DIXO** and **VANESSA K. VERDADE**, Universidade de São Paulo, Instituto de Biociências, Departamento de Ecologia, Departamento de Zoologia· CEP 05508-901, São Paulo, SP, Brazil (e-mail [MD]: maridixo@ib.usp.br).

ELEUTHERODACTYLUS FACTIOSUS. COLOMBIA: ANTIOQUIA: Anorí municipality: Chaquiral forest (6°58'44.3"N, 75°7'53.0"W). 13 November 2002. Museo de Herpetología Universidad de Antioquia, Medellín, Colombia (MHUA 3091, female). Amalfi municipality: Costa Rica forest (6°52'8.8"N, 75°6'12.5"W). 29 November 2002. MHUA 2442, 2448, females. La Secreta forest (6°49'33.7"N, 75°6'22.8"W). November 2002 and February 2003. MHUA 2452 (male), MHUA 2423 (female). El Edén forest (6°51'31.0"N, 75°5'16.1"W). 26 February 2003. MHUA 2438, male. All localities between 1750 and 1950 m elev. S. P. Galeano and J. C. Urbina. Verified by J. D. Lynch. First department record. Previously known only from Samaná and Pensilvania municipalities of Caldas department, Colombia (Lynch et al. 1998. Rev. Acad. Colomb. Cienc. 22[83]:287–298). These records extend the known distribution ca. 162 km NW from Samaná and ca. 167 km N from Pensilvania including the northern part of the Colombian Cordillera Central.

Submitted by **SANDRA P. GALEANO** (e-mail: spgaleano@yahoo.com) and **JENNY C. URBINA** (e-mail: jennyurbina@yahoo.com), Instituto de Biología, Universidad de Antioquia, AA. 1226 Medellín, Colombia.

ELEUTHERODACTYLUS GALDI (Espada's Robber Frog). PERÚ: PIURA: Provincia Huancabamba: Distrito Carmen de la Frontera: Santuario Nacional Tabaconas-Namballe (05°06'50.7"S, 79°21'16.3"W, 2200 m elev.). 24 April 2003. C. Aguilar. Museo de Historia Nacional, Universidad Mayor de San Marcos, Lima, Perú (MHNSM 19919–21), Museum fuer Tierkunde Dresden, Dresden, Germany (MTD 45969–64). Verified by J. M. Guayasamin. Specimens were caught in a primary forest, adults in vegetation 0.9–1.0 m above ground at night, juveniles on ground during day. Second record for Perú, northernmost distribution in Perú, first record for Departamento de Piura, and extension of altitudinal distribution (Duellman and Pramuk 1999. Sci. Pap., Nat. Hist. Mus. Univ. Kansas 13:1–78). First Peruvian record was based on a single juvenile specimen from 12 km E of La Peca in Departamento de Amazonas (Duellman and Pramuk, *op. cit.*). Our record extends the distribution within Peru ca. 130 air km NW from La Peca and extends the altitudinal distribution 225 m. Previously known high-

est altitudinal distribution was 1975 m (Duellman and Lynch, *op. cit.*). In comparison to Peru, *E. galdi* is well known from Ecuador where it is found at elevations of 1000–1740 m on the eastern face of the Cordillera Oriental (Lynch and Duellman 1980. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 69:1–86), 1700–1975 m in the Cordillera de Cutucú (Duellman and Lynch 1988. Proc. Acad. Nat. Sci. Phil. 140:125–142), and 1500–1550 m in the Cordillera del Cóndor (Almendáriz 1997. *In* Schulenberg and Awbrey [eds], RAP Working Papers No. 7, pp. 199–201, Washington, D.C., Conservation International; Lynch and Duellman, *op. cit.*).

HYLA CINEREA (Green Treefrog). USA: ARKANSAS: Little River Co: off St. Hwy 32, 3.2 km E Ashdown. 13 June 2004. Z. D. Ramsey. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28588). Verified by Stanley E. Trauth. New county record filling small distributional gap in southwestern Arkansas between records for Miller and Sevier counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **ZACHARY D. RAMSEY**, **STEPHANIE F. BARCLAY,** and **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA (e-mail: chris.mcallister@tamut.edu).

HYLA CINEREA (Green Treefrog). USA: INDIANA: Vanderburgh Co: Howell Slough at Howell Wetlands. NW1/2, NW1/4, Sec. 35, T6S, R11W. Scott Kramer and Michael J. Lodato 16 June 2003. Verified by Greg Schneider. University of Michigan Museum of Zoology, UMMZ 230109–110. First vouchered record for county and first vouchered record for Indiana. (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Acad. Sci. 404 pp.).

Green treefrogs were first located at this site by Scott Kramer, who heard chorusing males on various dates in May 2003. Specimens were first collected by Scott Kramer and James Horton on 14 June 2003 and kept in living collection of J. Horton. This new locality is about 7 km NW of a previously reported colony of *H. cinerea* in adjacent Henderson County, Kentucky (Lodato and Grannan 1990. Herpetol. Rev. 21:37). The origin of this newly reported population is unknown, i.e., previously overlooked resident, recent colonization, or introduction. However, this species has, in recent years, rapidly expanded its range and has shown to be a successful colonizer in adjacent southern Illinois (Redmer et al. 1999. Illinois Nat. Hist. Surv. Bull. Vol. 36, Art. 2, 66 pp.) and in adjacent western Kentucky (J. MacGregor, pers. comm.; B. Palmer-Ball, pers. comm.).

HYLA CRUZI. BRAZIL: MATO GROSSO DO SUL. Municipality of Cassilândia (19°08'S, 51°38'W), 471 m elev. 31 October 1996. I. A. Martins, J. Jim, E. F. Spirandeli-Cruz, and B. R. Cardana. Coleção Científica de Vertebrados do Laboratório de Zoologia da Universidade de Taubaté, São Paulo; (IAM/CCLZU 1402–11 males); 29 December 2002. I. A. Martins and S. C. Almeida. (IAM/CCLZU - males, 1037–65 and females, 1066–67), calling in permanent and temporary ponds. Verified by J. P. Pombal, Jr. Species previously known from type locality (Municipality Silvânia, Goiás, Brazil; Pombal and Bastos 1998. Bol. Mus. Nac. N.S. Zool., Rio de Janeiro, 309:1–14; Frost 2002. Amphibian Species of the World: An online reference V2.21 http://research.amnh.org/herpetology/amphibia/index.html.), and recently from Bolivia (Parque Noel

Kempff Mercado; Köhler 2003. Herpetol. Rev. 34:381). First state record extends known distribution ca. 500 km SSW from type locality (Pombal and Bastos, *op.cit.*) and ca. 1500 km SE from its known occurrence in Bolivia. This new record, in the State of Mato Grosso do Sul, confirms the wide distribution of this member of the *Hyla microcephala* group.

Submitted by **ITAMAR ALVES MARTINS,** Departamento de Biologia, Lab. de Zoologia da Universidade de Taubaté, 12030-010, Taubaté, SP, Brazil (e-mail: istama@uol.com.br.), and **SILVIO CESAR ALMEIDA**, **JORGE JIM**, **ELIETH FLORET SPIRANDELI CRUZ**, and **BENEDITO RINALDO CARDANA**, Departamento de Zoologia, Universidade Estadual Paulista, 18618-000, Botucatu, SP, Brazil.

HYLA PUNCTATA (Polka-dot Treefrog). VENEZUELA: ESTADO APURE: MUNICIPIO MUÑOZ: Hato El Frío. 65 m elev. 24 August 1981. R. Roca. Museo de la Estación Biológica de Rancho Grande, Maracay, Venezuela (EBRG 4425–4427). ESTADO YARACUY: MUNICIPIO SAN FELIPE: Parroquia Albarico, Parque Nacional Yurubí, Mayorica, Granja El Renacer. 260 m elev. 24 November 2000. E. Camargo-Siliet and F. Garcia (EBRG 4573–4575). 28 July 2000. E. Camargo-Siliet (EBRG 3680); 24 November 2000 (EBRG 3838–3839); 28 December 2000 (EBRG 3840–3842). Specimens, verified by Marco Natera, constitute first records for Apure and Yaracuy states. *Hyla punctata* is found from Trinidad and Guyanas south to Brazilian, Colombian, Ecuadorian and Peruvian Amazon, as well as Paraguay and Argentina (Frost 1985. Amphibian Species of the World: p. 149; La Marca 1992. Catálogo Taxonómico, Biogeográfico y Bibliográfico de las Ranas de Venezuela, Cuadernos Geográficos, Univ. Los Andes, 9:56, and map 29). The Yaracuy state record represents the northernmost locality for the species in continental South America, with the exception of a neglected Colombian specimen (holotype of *Hylella pearsei;* Ruthven 1922. Misc. Publ. Mus. Zool. Univ. Michigan 8:57) from Fundación, Sierra Nevada de Santa Marta, Colombia, collected more than 500 km W of the localities reported here, and considered by Cochran and Goin (1970. Frogs of Colombia, U.S. Nat. Mus. Bull. 288:224) as a synonym of *Hyla punctata*. The Yaracuy record extends the species range more than 800 km W and 450 km N from closest localities previously documented in Venezuela. Regionally, the species has been reported from eastern Venezuela (states of Delta Amacuro and Bolívar) and the upper Orinoco basin (Amazonas State) in the southern part of the country (Frost, *op. cit.*; La Marca, *op. cit.*; Barrio 1998. Acta Biol. Venezuel. 18[2]:33), as well as from Barinas State (Barrio et al. 2000. Herpetol. Rev. 31:50) and Táchira State (Chacón et al. 2002 Herpetol. Rev. 33:145).

Submitted by **EDWARD CAMARGO-SILIET**, Asociación Civil GEMA (Grupo de Exploraciones Científicas Minas de Aroa), Estado Yaracuy, Venezuela (e-mail: yaraculebra@hotmail.com), **RAMÓN RIVERO**, Museo de la Estación Biológica de Rancho Grande, Ministerio del Ambiente y de los Recursos Naturales, Oficina Nacional de Diversidad Biológica, Maracay, Venezuela (e-mail: museoebrg@cantv.net), and **ENRIQUE LA MARCA**, Laboratorio de Biogeografía, Escuela de Geografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Mérida 5101, Venezuela (e-mail: lamarca1@telcel.net.ve).

HYLA SQUIRELLA (Squirrel Treefrog). USA: TEXAS: CAMERON Co. South Padre Island (26°5'8.29"N, 97°9'48.89"W). 14–16 May 2004. Collected by Rebecca M. Calisi. Verified by Jonathan A. Campbell and John H. Malone. A series of 28 juveniles were sampled from landscaped, grassy area along Bridgepoint Luxury Condos driveway, 334 Padre Boulevard, South Padre Island, Texas, 78597 (UTA A-56636–663). Numerous juveniles observed, and adults were calling south of the condo parking lot in conjunction with *Hyla cinerea*. First confirmed county record. Nearest occurrence documented in Kleberg Co., two counties north of Cameron Co. (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M Press, College Station, Texas. 182 pp.).

Submitted by **REBECCA M. CALISI**, Department of Biology, University of Texas at Arlington, 501 South Nedderman, Life Science Building 337, Arlington, Texas 76019, USA; e-mail: calisiB@aol.com.

LEPIDOBATRACHUS LLANENSIS. BOLIVIA: DEPARTAMENTO TARIJA: Provincia Gran Chaco: ca. 50 km from Villamontes towards Paraguayan border (21°29'28"S; 63°3'7"W). 2 January 2004. S. Reichle and D. Embert. Museo Historia Natural Noel Kempff Mercado, Santa Cruz, Bolivia (MNKR 7600). First country record. Previously known from Argentina and Paraguay. The new record extends the known distribution 100 km N from the nearest locality—"Hickman"—in the Salta Province in Argentina (23°12'S; 63°34'W) (Faivovich 1994. Acta Zool. Lilloana 43[1]:105–115).

Submitted by **STEFFEN REICHLE**, The Nature Conservancy – Bolivia Program, Edificio Multicentro Torre B, piso 4 ofc. 402, La Paz, Bolivia; **DIRK EMBERT,** Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany; and **JULIAN FAIVOVICH**, Department of Herpetology, American Museum of Natural History, New York, New York 10024, USA.

LEPTODACTYLUS STENODEMA (San José White-lipped Frog). PERÚ: MADRE DE DIOS: Manu: Río Los Amigos Conservation Concession, Río Los Amigos Research Center (12°34' S, 70°06' W, 270 m elev.). 7 April 2003. E. Chulla, M. Medina, N. Carrillo, R. von May. Verified by W. R. Heyer. Museo de Historia Natural Universidad San Marcos, Lima, Perú (MUSM 21069, juvenile, 62.3 mm SVL collected at 2000 h on leaf litter, near a burrow between tree roots in an old-growth tierra firme forest ca. 2.6 km NW from research center). First record for Madre de Dios Department and extension of southern limit of its range in Perú and in South America (Rodríguez et al. 1993. Publ. Mus. Hist. Nat. UNMSM [A] 45:1–22; Duellman and Thomas 1996. Occas. Pap. Mus. Nat. Hist. Univ. Kansas 180:1–34; Heyer 1979. Smithson. Contr. Zool. 301:1–43). The nearest known locality is Balta, Ucayali Department, Perú (ca. 300 km NW) (Duellman and Thomas 1996, *op cit.),* which was the southernmost record (10°08' S) within the known range for this species that includes part of the Amazon Basin in Ecuador, Colombia, Perú, Brazil, and part of the Guianas (Heyer 1979, *op cit.).*

Submitted by **RUDOLF VON MAY**, Asociación para la Conservación de la Cuenca Amazónica (ACCA), Calle Cuzco 499, Puerto Maldonado, Madre de Dios, Perú; e-mail: vonmay@terra.com.

NYCTIXALUS PICTUS (White-spotted Tree Frog). THAILAND. NAKHON SI THAMMARAT PROVINCE: KHAO LUANG NATIONAL PARK: Khao Luang (ca. 8°27'N, 99°37'E). No date. M. Matsui. Graduate School of Human and Environmental Studies, Kyoto University (KUHE 19435). Verified by J. Nabhitabhata. Single adult. RANONG PROVINCE: Muang District: forest stream near Klong Hat Som Paen (ca. 9°57'N, 98°41'E). 9 January 2003. C. Chimsunchart, M. Sumontha, and O.S.G. Pauwels. Institut Royal des Sciences naturelles de Belgique, Brussels (IRSNB 13241). Verified by C. Chimsunchart. Single adult, found at 2235 h on a shrub along the water, 1.5 m above the ground. First records for both provinces. The closest records in Thailand are from Raman Forest Park (Pauwels et al. 2000. Abstracts. Fourth Asian Herpetological Conference. 16–20 July 2000, Chengdu, China: 137; voucher specimen in Muséum National d'Histoire Naturelle, Paris) and Laem Hin Chang (Grossmann and Tillack 2000. Sauria 22[4]: 23–38), Phang-Nga Province, southern Thailand. The locality in Ranong Province is situated at ca. 145 air km N of the previous northernmost locality for *N. pictus* in mainland Southeast Asia, and less than 20 air km from Myanmar, where the species has not yet been recorded.

We thank C. Chimsunchart (Phetchaburi), A. Aowphol and K. Thirakhupt (Chulalongkorn University, Bangkok), and G. Coulon and G. Lenglet (IRSNB) for help and working facilities.

Submitted by **OLIVIER S. G. PAUWELS**, Department of Recent Vertebrates, Institut Royal des Sciences naturelles de Belgique, Rue Vautier 29, 1000 Brussels, Belgium (e-mail: osgpauwels@hotmail.com), **MONTRI SUMONTHA**, Ranong Marine Fisheries Station, 157 M. 1, Saphan-Pla Rd., Paknam, Muang, Ranong 85000, Thailand (e-mail: montri_sumontha@hotmail.com), and **MASAFUMI MATSUI**, Graduate School of Human and Environmental Studies, Kyoto University, Sakyo, Kyoto 606-8501, Japan (e-mail: fumi@zoo.zool.kyoto-u.ac.jp).

OSTEOCEPHALUS BUCKLEYI (Buckley's Slender-legged Treefrog). PERÚ: MADRE DE DIOS: Manu: Río Los Amigos Conservation Concession, Río Los Amigos Research Center (12°34'S, 70°06'W, 270 m elev.). 14 February 2002, 10 March 2003, 1 April 2003. R. von May, N. Carrillo. Museo de Historia Natural Universidad San Marcos, Lima, Perú (MHNSM 19225, male 39.8 mm SVL; MHNSM 19226, male 38.6 mm SVL; MHNSM 19227, female 50.9 mm SVL. Collected between 2000 and 2400 h, on understory vegetation 0.6–1.4 m above ground, in an old-growth tierra firme forest ca. 2.5 km N and 3.5 km NW from research center.). Verified by K.H. Jungfer. First record for Madre de Dios Department and second record for southern Perú (Rodríguez et al. 1993. Publ. Mus. Hist. Nat. UNMSM [A] 45:1–22; Duellman and Thomas 1996. Occas. Pap. Mus. Nat. Hist. Univ. Kansas 180:1–34; Trueb and Duellman. 1971. Occas. Pap. Mus. Nat. Hist. Univ. Kansas 1:1–47). The nearest known localities in Perú are: Balta, Ucayali Department (ca. 300 km NW) (Duellman and Thomas 1996, *op. cit.*) and Yahuaramayo, Puno Department (ca. 150 km S) (Trueb and Duellman 1971, *op. cit.*). This record fills a hiatus of ca. 450 km in the southwestern region of the known range for this species. This includes the periphery of the Amazon Basin in the Guianas and northeastern Brazil, as well as part of the Amazon Basin in southern Colombia, Ecuador, Perú, and east-central Bolivia (Trueb and Duellman 1971, *op. cit.*).

RHAMPHOPHRYNE MACRORHINA (Billed Toad, Trumpeted Toad). COLOMBIA: ANTIOQUIA: Anorí Municipality: La Forzosa Forest (6°58'54.1"N, 75°8'41.6"W). 11 November 2002.

Museo de Herpetología Universidad de Antioquia, Medellín, Colombia (MHUA) 2343, a male; Chaquiral Forest (6°58'44.3"N, 75°7'53.0"W). 15 November 2002. A male (MHUA 2344). Amalfi Municipality: Costa Rica Forest (6°52'8.8"N, 75°6'12.5"W). November and February 2002. A female (MHUA 2445) and two males (MHUA 2446–47). Los Canales Forest (6°49'46.1"N, 75°5'18.8"W). November 2002. A female (MHUA 2345) and a male (MHUA 2346). All localities between 1800 and 1980 m elev. Individuals found on leaf litter during the day and on terrestrial bromeliads at night, within interior forest. S. P. Galeano and J. C. Urbina. Verified by J. D. Lynch. Previously known from the Guatapé Municipality in Antioquia (Trueb 1971. Los Angeles Co. Mus. Contr. Sci. 216:1–40) and from Samaná Municipality in Caldas, Colombia (Rueda et al. [eds.] 2004. Libro Rojo de Anfibios de Colombia. Serie Libros Rojos de Especies Amenazadas de Colombia. C I Colombia, ICN – UNAL Colombia, Ministerio del Medio Ambiente. Bogotá, Colombia). This record extends the known distribution 75 km NE from Guatapé and ca. 162 km NW from Samaná including the northern part of the Colombian Cordillera Central.

Submitted by **SANDRA P. GALEANO** (e-mail spgaleano@yahoo.com) and **JENNY C. URBINA,** Instituto de Biología, Universidad de Antioquia, AA. 1226 Medellín, Colombia (e-mail: jennyurbina@yahoo.com).

XENOHYLA EUGENIOI (NCN). BRAZIL: BAHIA: Ipirá (12°09'S, 39°44'W). 328 m elev. 4 April 1995. Amphibian Collection, Museu de Zoologia, Universidade Federal da Bahia, Salvador, Bahia, Brazil (UFBA 050). Verified by U. Caramaschi. This new record is the northernmost for the species, and extends its range 161.5 km N from the type locality, Maracás, Bahia, Brazil (13°25'S, 40°25'W, 964 m elev.) (Caramaschi 1998. Amphibia-Reptilia 19:377–384). Only two other localities are known for this species: Poções, Bahia (14°32'S, 40°22'W), and Planalto Baiano, Bahia (14°40'S, 40°28'W).

Submitted by **MARCELO FELGUEIRAS NAPOLI** (e-mail: napoli@ufba.br) and **FERNANDA BRANDÃO**, AMPHIBIA – Laboratório de Taxonomia e História Natural de Anfíbios, Departamento de Zoologia, Instituto de Biologia, Universidade Federal da Bahia, Campus Universitário de Ondina, Rua Barão de Geremoabo, 40170-290 Salvador, Bahia, Brazil.

TESTUDINES

BATAGUR BASKA (River Terrapin). CAMBODIA: KOH KONG: Botum Sakor District: Stung Proat River (11°19'52"N 103°27'57"E), 24 October 2003. Juvenile (BW 1900 g, CL 246 mm). Photographic collection, Museum of Vertebrate Zoology (MVZ 241558). Verified by J. F. Parham. First district record and westward extension of known range of the species within Cambodia, although this endangered terrapin is known from neighboring Sre Ambel District (Platt et al. 2003. Chelonian Conserv. Biol. 4:691–694). This individual was handed to the Sre Ambel District Fisheries officer. It was speared with a four-pronged spear by Mr. Tuong of Chiphat Village while he was fishing for shrimp 31.5 km from the river mouth, at a salinity 20% of sea water. It was maintained in captivity for a week before it was released where Mr. Tuong caught it.

PSEUDEMYS CONCINNA (Eastern River Cooter). USA: ARKANSAS: Miller Co: 10.2 km WSW Fouke off AR St. Hwy 237 at Sulphur River Bridge. 25 March 2004. N. E. Solley. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28309). Verified by Stanley E. Trauth. New county record (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville. 421 pp.) filling a distributional hiatus in extreme SW part of state. Also reported previously to the west in nearby Bowie (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.) and Cass (McAllister 2001. Herpetol. Rev. 32:117) counties, Texas.

Submitted by **NANCY E. SOLLEY** and **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA; e-mail: chris.mcallister@tamut.edu.

RHINOCLEMMYS PULCHERRIMA ROGERBARBOURI (Western Mexican Wood Turtle). MÉXICO: CHIHUAHUA: Municipality of Chínipas, La Cienaga (27°27'27.5"N, 108°34'50.9"W), 600 m elev. 22 September 2003. Julio A. Lemos-Espinal. Herpetological Collection Photograph, Laboratorio de Ecología, Unidad de Biología, Tecnología y Prototipos (UBIPROo-00002). Verified by Luis Oliver-López. First valid record from Chihuahua, and a range extension of about 75 km E of Guirocoba, Sonora (Bogert and Oliver 1945. Bull. Am. Mus. Nat. Hist. 83:396). Another record reported from the state was invalidated by Ernst (1981. Cat. Am. Amph. Rept. [275]:1), who determined it to be a released or escaped animal that undoubtedly came from another locality.

Submitted by **HOBART M. SMITH** (e-mail: hsmith@colorado.edu) and **DAVID CHISZAR**, Department of Ecology and Evolutionary Biology, and Museum, University of Colorado, Boulder, Colorado 80309, USA (e-mail: chiszar@clipr.colorado.edu), and **JULIO A. LEMOS-ESPINAL** (e-mail: lemos@servidor.unam.mx) and **GUILLERMO WOOLRICH-PIÑA**, Laboratorio de Ecología, Unidad de Biología, Tecnología y Prototipos, Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México, Apartado Postal 314, Avenida de los Barrios #1, Los Reyes Iztacala, Tlalnepantla, Estado de México, México 54090 (e-mail: woolrich@correo.unam.mx).

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). USA: ARKANSAS: Little River Co: off St. Hwy 108, 3.2 km SE Alleene. 13 June 2004. M. L. Cameron. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28589). Verified by Stanley E. Trauth. New county record filling hiatus in southwestern Arkansas between records for Miller and Sevier counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville. 421 pp.). We anticipate that *T. c. triunguis* will be documented in adjacent Hempstead County thus placing this species in all counties of western Arkansas.

Submitted by **MICHELLE L. CAMERON** and **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA (e-mail: chris.mcallister@tamut.edu).

LACERTILIA

ANOLIS CAROLINENSIS CAROLINENSIS (Northern Green Anole). USA: ARKANSAS: Little River Co: 1.6 km SE Wilton off U.S. 71 on County Rd. 201. 28 March 2004. A. R. Shoemake. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28310). Verified by Stanley E. Trauth. New county record completely filling small distributional gap in southwestern Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **ALICIA R. SHOEMAKE** and **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA (e-mail: chris.mcallister@tamut.edu).

ANOLIS CAROLINENSIS CAROLINENSIS. (Northern Green Anole). USA: TENNESSEE: Hickman Co.: Sulpher Creek Road ca. 1.0 road mi NW of Beaverdam Springs (Camp Nocome) (35°41'31"N,87°36'30"W). 23 March 2004. David Anderson. Austin Peay State University Museum of Zoology (APSU 17487, 2 color photos). Verified by A. Floyd Scott. One adult observed on south-facing bank of roadside ditch near 3rd-order stream (Sulphur Creek) in beech-maple forest. New county record and northernmost documented locality for the species in middle Tennessee (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians. Eastern and Central North America. Houghton Mifflin, Boston, Massachusetts. 616 pp.). Previously reported from the following central Tennessee counties: Hardin (Truett 1993. M.S. Thesis, University of Tennessee, Knoxville, 55 pp; Cahn 1939. Copeia 1939:169), Wayne (Cochran 1938. Copeia 1938:90; Gentry 1956. J. Tennessee Acad. Sci. 31:242–251); Lawrence, Giles, Lincoln, Franklin (Gentry 1956, *op. cit.*).

Submitted by **DAVID ANDERSON**, 1150 Riverview Road, Centerville, Tennessee, 37033, USA; e-mail: dandm5@bellsouth.net.

CYRTODACTYLUS IRREGULARIS (Irregular Bent-Toed Gecko). VIETNAM: THUA THIEN HUE: Bach Ma (16°05–16'N, 107°43–53'E). Collected before August 1998. Hoang Xuan Quang and students. Verified by Wolfgang Böhme. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 80080). *Cyrtodactylus irregularis* was previously only known from the northern part of southern Vietnam and the southern part of central Vietnam (Smith 1935. The Fauna of British India, including Ceylon and Burma. Reptilia and Amphibia. Vol. II. Sauria. Taylor & Francis Ltd., London; Bobrov 1993. Zoologicheskii Zhurnal 72:70–79), in particular the provinces Lam Dong, Dac Lac, and Gia Lai (Nguyen Van Sang and Ho Thu Cuc 1996. Danh luc bo sat va ech nhai Viet Nam. Nha xuat ban khoa hoc va ky thuat, Ha Noi). The new finding represents the first record for the northern part of central Vietnam (compare www.wing-wbsj.or.jp/~vietnam/source_book/index.htm for geographical zones) and thus is the northernmost record of the species in Vietnam and in general. The specimen of Bach Ma is most likely a female (SVL 51.0 mm; head length 14.0 mm; head width 8.7 mm; head height 6.2 mm; tail incomplete); its stomach and gut contained remains of a cricket or grasshopper (Saltatoria) of

about 15 mm head–body length. ZFMK 80080 differs from the original description (Smith 1921. Proc. Zool. Soc. London 1921:423–440) in pattern. However, the neck and back pattern of the present specimen corresponds well with that of another specimen (BM 1931.6.12.3 from Sui Kat) tentatively placed in *C. irregularis* by Smith (1935). The scalation features of the specimen of Bach Ma (12 supralabials; 8 sublabials; 4 nasals; 1 internasal; 2 postmentals; 6 scales behind postmentals; 20 rows of dorsal tubercles; ca. 47 ventrals between lateral folds at midbody; ca. 9 enlarged preanal scales, situated in an angle, and followed up with two rows of distinctly enlarged, smooth scales; 21–23 subdigital lamellae below fourth toe; subcaudals larger than dorsal tail scales but not in a longitudinal, medial row) largely correspond with the characters given in Smith (1935), except for the lack of enlarged femoral scales. Apparently, *Cyrtodactylus irregularis* is a rarely collected and therefore barely known bent-toed gecko species.

R. Vietnam.

COLEONYX ELEGANS (Yucatán Banded Gecko). MÉXICO: PUEBLA: Municipality of Huehuetlán El Chico, Mixteca Poblana (18°21'19"N, 98°41'27.1"W), 1055 m elev. 8 September 2000. Demian Solis Cuautle. Laboratorio de Herpetología, Escuela de Biología, Benemérita, Universidad Autónoma de Puebla (EBUAP 2046). Verified by Edmundo Perez Ramos. First record for the state and a ca. 58 km range extension from the nearest locality in Morelos (Castro-Franco and Bustos-Zagal 2003. Acta Zool. Mex. 88:123–142). The specimen was caught in tropical deciduous forest.

Submitted by **LUIS CANSECO-MÁRQUEZ**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México (e-mail: lcm@correo.unam.mx); **GUADALUPE GUTIÉRREZ MAYÉN**, Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México; **URI OMAR GARCÍA-VÁZQUEZ** and **CARLOS HERNÁNDEZ-JIMËNEZ**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México.

EUGONGYLUS RUFESCENS. INDONESIA: EAST SUMATRA: Jambi Province: Kersic Tui District. Rainforest in the Sangaranaguna River Valley, near a volcanic lake, Danan Gunung Tujnh (1900 m elev.). 19 November 1999. Nikolai Orlov. Zoological Institute, Russian Academy of Sciences (ZISP 22613). Verified by Natalia Ananjeva. Adult male, 110 mm SVL, 31 rows of scales at mid-body, 69 mid-dosal scales between parietal scales and a point above vent, 15 smooth lamellae under 4th toe. New island record. Known localities of this relatively large skink (reaching 150 mm SVL at maximum) range from the islands of Timor, Ambona, Ceram, Aru, and Molluccas, through New Guinea and some adjacent islands including those in the Torres Strait, to northern Cape York of Australia and the Solomon Islands (Rooij 1915. The Reptiles of Indo-Australian Archipelago 1. Lacertilia, Chelonia, Emidosauria. Brill, Leiden; Greer 1974. Austral. J. Zool., Suppl. Ser. 31; Welch et al. 1990. Lizards of the Orient: A Checklist. Krieger Publ. Co., Malabar, Florida). This very unexpected discovery of *E. rufescens* from Sumatra extends the species' range, as well as generic range, westward by more than 2500 km. Because the present specimen was collected at a high altitude, it seems unlikely that it had originated from recent migration to Sumatra by means of rafting or of artificial transportation. We suspect that the specimen represents a relict population of the species, which should once have exhibited a continuous distribution, but then disappeared from islands located between Sumatra and eastern Indonesia.

Submitted by **ILYA DAREVSKY** (e-mail: lacerta@zin.ru) and **NIKOLAI ORLOV,** Zoological Institute, Russian Academy of Sciences, 199034 St. Petersburg, Russia.

GEKKO MONARCHUS (Spotted House Gecko). WEST MALAYSIA: PAHANG: Pulau Sembilan. 22 July 2003. Cindy M. Valdivia, Linda Escobar, Nicole Padilla, Jonathan Wheatley, Steven Wright, Siewyeen Teen, and Robert Rosser. Forest Research Institute, Malaysia (FRIM) 0620. Verified by Jesse L. Grismer. Two males were collected, of which one (87 mm SVL) was found at ca. 2000 h on a large boulder in a dry streambed, and the other (86 mm SVL) at ca. 2100 h, ca. 1 m above ground on a small dipterocarp tree along the same dry streambed. Only one of these was deposited as a voucher specimen (see above); the other was released after examination and identification. The current distribution of *G. monarchus* ranges throughout southern Thailand, West Malaysia, Singapore, Borneo, Sumatra, Java, Sulawesi, New Guinea, and the Philippines (Manthey and Grossman 1997. Amphibien und Reptilien Südostasiens. Natur und Tier-Verlag, Münster, Germany. 233 pp.). Within the Seribuat Archipelago, West Malaysia, *G. monarchus* occurs in Pulau Aur, Pulau Dayang, Pulau Pemanggil, Pulau Seribuat, Pulau Tinggi, and Pulau Tioman (Escobar et al. 2003. Hamadryad 27:259–262; Grismer et al. 2001. Hamadryad 26:322–325; Wood et al. 2003. Hamadryad 27:281–284; Wood et al. 2004. Hamadryad, *in press*; Youmans et al. 2002. Hamadryad 27:148–149). It is not surprising to find *G. monarchus* on Pulau Sembilan because of its proximity (0.7 km W) to Pulau Seribuat, where *G. monarchus* occurs (Wood et al. 2003, *op. cit.*).

Submitted by **CINDY M. VALDIVIA, LINDA ESCOBAR, NICOLE PADILLA, JONATHAN WHEATLEY, STEVEN WRIGHT, SEWYEEN TEEN,** and **ROBERT ROSSER**, Department of Biology, La Sierra University, Riverside California 92515-8247, USA; e-mail: cm_valdivia@yahoo.com.

GERRHONOTUS LIOCEPHALUS (Texas Alligator Lizard). MÉXICO: ZACATECAS: Municipality of Valparaíso, El Romerillo, 4 km N, 1.5 km W Valparaíso (22°46.2'N, 103°34'W), 1980 m elev. 27 September 2002. Lesley Chambert. Verified by Adrián Nieto-Montes de Oca. Herpetological Collection of the Escuela Nacional de Ciencias Biológicas (IPN. ENCB-17383). First record for Zacatecas and extends range ca. 139.5 airline km SE from Llano Grande, Durango (Good 1994. Herpetol. Monogr.

8:180–202) and ca. 146 airline km NW from Sierra del Laurel, Aguascalientes (Ramírez-Bautista 1998. Herpetol. Rev. 29:110. The specimen was collected in a transition zone between dry pine-oak forest and xerophytic shrubs.

Submitted by **JOSÉ ISMAEL CAMPOS-RODRÍGUEZ** (e-mail: ismaelcampos@msn.com), **LESLEY CHAMBERT,** and **MARÍA DEL CARMEN DÍAZ**, Laboratorio de Cordados Terrestres, Departamento de Zoología, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Apdo. GYMNOPHTHALMUS UNDERWOODI (Smooth-scaled Worm Lizard). ST. VINCENT: The Grenadines: Mustique Island, intersection of the road connecting Macaroni Beach with Pasture Bay and the road leading to Britannia Bay (250 m inland from the eastern coast), 50 m elev. 2 February 2002 and 3 February 2003. M. R. Paice. Verified by Robert Powell. MPM Herpetology Photographic Collection 711–12. Photographed midday in partially shaded roadside leaf-litter near xeric woodland. First record for Mustique Island (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. xvi + 720 pp.).

Submitted by **MICHAEL R. PAICE**, 8D Rochdale Way, London SE8 4LY, UK (e-mail: mrpaice@yahoo.co.uk), and **ROBERT W. HENDERSON**, Section of Vertebrate Zoology, Milwaukee Public Museum, Milwaukee, Wisconsin 53233-1478, USA (e-mail: rh@mpm.edu).

HEMIDACTYLUS AGRIUS. BRAZIL: MARANHÃO: Urbano Santos Municipality: Fazenda Bonfim (3°21'14"S, 43°09'05"W; ca. 40 m elev.). 23 July 2002. J. O. Gomes, L. D. Cruz, and P. C. Freire. Museu de Zoologia da Universidade de São Paulo, São Paulo, São Paulo, Brazil (MZUSP 93079, adult). 31 May 2003. J. O. Gomes, P. C. Freire. (MZUSP 93078, adult). Verified by M. T. Rodrigues. Published distribution is restricted to the caatinga of Ceará and Piauí states (Vanzolini et al. 1980. Répteis das Caatingas. Academia Brasileira de Ciências, Rio de Janeiro, 161 pp.; Rodrigues 1986. Pap. Av. Zool. 36:237–250), in northeastern Brazil, including open areas of the relic forest in semiarid caatingas in the state of Ceará (Borges and Caramaschi 2003. *In* Ecologia e Conservação da Caatinga. Recife: UFPE, v. 01, pp. 489–540). New state records, extends range ca. 270 km W in northeastern Brazil, and extend the distribution of this species to the domain of the Cerrado.

Submitted by **GILDA V. ANDRADE** (e-mail: gandrade@ufma.br), **JERRIANE O. GOMES** (e-mail: jerrianegomes@yahoo.com.br), **PEDRO C. FREIRE**, and **LEONARDO D. CRUZ**, Universidade Federal do Maranhão, Departamento de Biologia, Campus do Bacanga, CEP 65080-040, São Luís, Maranhão, Brazil.

HEMIDACTYLUS GARNOTII (Indo-Pacific Gecko). USA: FLORIDA: SUWANNEE COUNTY: Live Oak, jct. of US 129 and 2nd Street N.E. (30°18'15"N, 82°58'50"W). 11 June 2004. Cory R. Lindsay and Josiah H. Townsend. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 141645). New county record (Townsend and Krysko 2003. Florida Sci. 66:204–208). Juvenile, active on a concrete wall at SuperTest service station at 2300 h. This specimen extends the range of the non-native *H. garnotii* ca. 88.5 km W of the nearest locality in Maclenny, Baker Co., and ca. 104.6 km NNW of the next nearest locality in Gainesville, Alachua Co. (Townsend and Krysko, *op. cit.*).

Submitted by **JOSIAH H. TOWNSEND**, Division of Herpetology, Florida Museum of Natural History, and Center for Latin American Studies, University of Florida, Gainesville, Florida 32611, USA (e-mail: jtownsend@flmnh.ufl.edu), and **CORY R. LINDSAY**, Department of Anatomy and Cell Biology, College of Medicine, University of Florida, Gainesville, Florida 32610, USA (e-mail: clindsay@ufl.edu).

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: ARKANSAS: JEFFERSON CO: 2700 East Harding Ave., Pine Bluff, (34°12.669'N, 91°58.456'W). 4 June 2004. Coleman M. Sheehy III. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida, Gainesville (UF 141606–08). New county record. Collected three (53.4, 50.7, and 43.8 mm SVL, respectively) and observed ca. 10 additional individuals on walls of building at 0500 h. *Hemidactylus turcicus* was first reported in Arkansas from Sebastian County in the early 1970s (Paulissen and Buchanan 1990. Herpetol. Rev. 21:22). This species subsequently has been found in six additional counties, and remains the only established exotic herpetofaunal species in Arkansas (Trauth et al. 2004, The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press. 421 pp.).

Submitted by **COLEMAN M. SHEEHY III**, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA; e-mail: csheehy@flmnh.ufl.edu.

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: TEXAS: HARDIN CO: Village Creek State Park, 0.8 km E Lumberton. 15 June 2004. C. T. McAllister. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28625). Verified by Stanley E. Trauth. New county record falling between records for Jasper and Jefferson counties (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. 421 pp.). Thriving population, including juveniles, gravid females, and adult males found dispersed among wood crevices of state park restroom. This introduced species has now been reported from at least 71 of 254 counties of the state.

Submitted by **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA; e-mail: chris.mcallister@tamut.edu.

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: TEXAS: LUBBOCK CO: Commercial business building (Blue Star Candles) at UTM Easting 0236269, Northing 3717543 (33°33'54"N, 96°09'32"W), eastern Lubbock city limits. Collected by Waymouth Roberts, 20 February 2003, verified by J. Baldwin. University of Texas at Arlington (UTACV R-52460). This juvenile specimen represents the first official county record, although this species has inhabited the city of Lubbock for at least a decade

(L. Densmore, pers. comm.). This extends the range ca. 354 km NW in Texas from Taylor Co. (Landwer and Lee 2001. Herpetol. Rev. 32:119). Perhaps because this is an introduced species with a rapidly expanding distribution (as explained by Bauer 2000. Herpetol. Rev. 31:72–73), especially in Texas, the effort to report its official occurrence in Lubbock County has until now been neglected. This may represent Texas' most northwestern county to have long-term established populations of this species.

Submitted by **ANDREW S. BALDWIN**, Mesa Community College, Department of Life Science, 1833 West Southern Avenue, Mesa, Arizona 85202, USA.

LIOLAEMUS CYANOGASTER CYANOGASTER (Blue Belly Lizard, Lagartija de Vientre Azul). CHILE: VII REGIÓN DEL MAULE, Cauquenes Province, Tregualemu, pine (*Pinus radiata*) plantations surrounding Reserva Nacional Los Queules (35°59'19"S, 72°41'15"W, 180 m elev.). 17 January (adult male, 57 mm SVL; MNHN 3785) and 20 March 2004 (adult male, 61.7 mm SVL; MNHN 3786). A. Rubio and F. Zorondo-Rodríguez. Herpetological collection, Museo Nacional de Historia Natural de Chile, Santiago, Chile. Verified by A. Veloso. This species ranges from Concepción (37°00'S, 70°00'W), VIII Region, to Puerto Montt (41°28'S, 72°57'W), X Region (Donoso-Barros 1966. Reptiles de Chile. Ediciones Universidad de Chile, Santiago, Chile; Veloso and Navarro 1988. Bollettino del Museo Regionale di Scienze Naturali Torino 6:481–539). The record reported herein extend its known range two degrees north (over 200 km). Another individual was observed nearby on 23 April 2004 (35°58'26"S, 72°38'38"W, 473 m elev.), in a reduced remnant of Maulino forest comprised of *Nothofagus obliqua* and *N. glauca*. The northward extension in the species range adds to changes in the known distribution of several species usually regarded as typical of the more southernValdivian forest, such as the microbiotherid *Dromiciops gliroides*, the rodents *Irenomys tarsalis* and *Geoxus valdivianus* (Saavedra and Simonetti 2000. Mammal. Biol. 65:243–245; Saavedra and Simonetti 2001. Mammalia 65:96–100), the short-tailed snake *Tachymenis chilensis chilensis* (Simonetti 2001. Gayana 65:219–220), and several ground beetles (Grez et al. 2003. Rev. Chil. Entomol. 29:9–18), reinforcing the "Valdivian forest" type attributes of the Maulino forest fauna. This new locality has been recorded with the partial support of grant Fondecyt 1010852.

Submitted by **ANDRÉ RUBIO** (e-mail: tranebird@yahoo.com), **FRANCISCO ZORONDO-RODRÍGUEZ** (e-mail: panchozr@esfera.cl), and **JAVIER A. SIMONETTI** (e-mail: jsimonet@uchile.cl), Departamento de Ciencias Ecológicas, Facultad de Ciencias, Universidad de Chile, Casilla 653, Santiago, Chile.

LEIOLEPIS REEVESII RUBRITAENIATA. VIETNAM: GIALAI PROVINCE: Chu Prong District, 15 km E of the Vietnam-Campuchia border. In the primary tropical forest on the Iamo River bank, predominated by dipterocarpasean trees, floored with sandy and stony soil. April 2000. Nguyen Van Sung. Institute of Ecology and Biological Resources (IEBR S 0401–0404). Verified by Natalia Ananjeva. First country record. This subspecies was originally described from northern Thailand (Paktjong, 160 km NE of Bangkok) under the name *Leiolepis belliana rubritaeniana* (Mertens 1961. Senckenbergiana biologica 42:507–510), and later from other localities in the western and central parts of northern Thailand (Taylor 1963. Univ. Kansas Sci. Bull. 44:687–1077). In his revision of the genus *Leiolepis*, Peters (1971. Zool. Jb. 98:11–130), while moving this subspecies to *L. reevesii,* argued that its range is confined to the Khorat Plateau in northeastern Thailand and the southwestern extremity of Laos. Our discovery extends the known range of *L. reevesii rubritaeniata* southeastward by at least 500 km. It also predicts occurrence of this subspecies in Campuchia, because it intervenes between southern Vietnam and other parts of previously known range of the subspecies. It is interesting to note that the range of this butterfly lizard in Vietnam is remote (ca. 200 km) from sea, because all other Vietnamese congeners *(L. r. reevesii, L. guttata, L. belliana,* and *L. guntherpetersi)* chiefly inhabit sandy dunes with sparse xerophilic vegetation near the coast (usually within 1–3 km from the coastline: Darevsky and Kuprijanova 1993. Herpetozoa 6:3–20). Gonads of three sexually mature specimens (two males and one female) of the present sample looked much depressed, suggesting that reproduction had taken place earlier. This is of interest because the reproductive season of *L. r. reevesii* in Vietnam includes April (Darevsky and Kuprijanova, unpubl.). This, along with differences in a few meristic characters in pholidosis, body coloration, and degree of sexual dimorphism between *L. reevesii rubritaeniata* and the nominotypical subspecies (to be published elswhere), suggests that the former may actually deserve recognition as an independent species. Definitive determination of taxonomic status will require molecular analysis sensu Schmitz et al. (2001. Zool. Abh. Staatliches Mus. Tierkunde Dresden 51:355–360).

Submitted by **ILYA DAREVSKY**, Zoological Institute, Russian Academy of Sciences (e-mail: lacerta@zin.ru), and **NGUYEN VAN SUNG**, Institute of Ecology and Biological Resources, National Center for Natural Science and Technology of Vietnam, Hanoi, Vietnam (e-mail: nguyen@iebr.nc.vn).

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). FRENCH POLYNESIA: TUBUAI (AUSTRAL) ISLANDS: Raivavae Island: Hotuatua, a small islet W of Raivavae (23.85709°S, 147.61591°W), at sea level in a *Hibiscus tiliaceus* forest. MNHN 2002.0984. Triploid specimen belonging to clone B. 25 November 2002. Olivier Gargominy and Benoît Fontaine. Verified by Roger Bour. First island record. This unisexual-bisexual complex was previously only known from Rurutu, Tubuai, and Rapa in the Tubuai Islands. It may also be present on the main island of Raivavae (= Vavitao). Its occurrence on Rimatara remains undocumented (Ineich and Blanc 1988. Atoll Res. Bull. 318:1–75).

PODARCIS MURALIS (Common Wall Lizard). CANADA: BRITISH COLUMBIA: West Saanich, Durrance & Rudy Road. On 1 October 2002, GD observed four adults and 20 juveniles at the site of a former zoo which is now a private garden. The following day GD observed three juveniles on a power line road 250 m farther west.

In an interview with Mrs. Brigitte Wolff, she stated that in 1970 her father, Rudy Bauersachs, now deceased, released a dozen *P. muralis* on his land on Durrance Road after the closing of Rudy's Petpark Zoo. In addition, six lizards were released in each of the gardens of two of Mrs. Wolff's sons in Summerland, BC in 1983 and another six lizards on Triangle Mountain near Sooke, BC (Greater Victoria area) in 1986 by her third son. The Summerland group did not survive. The Triangle Mountain group became established, and according to Mrs. Wolff, "expelled the brown native lizards there" (*Elgaria coerulea*). This statement contradicts Allan et. al. who in a March 1993 report to the British Columbia Ministry of Environment report ("The Ecology of Introduced Common Wall Lizards [*Podarcis muralis*] in Saanich, Vancouver Island") concluded that there is no compelling evidence of *Podarcis* threatening *Elgaria* on Vancouver Island. As of 2000, the Vancouver Island population was still growing (Allan et. al. 2000. Herpetol. Rev 31:160–161).

We extracted total DNA from two samples (Russell L. Burke personal collections, RLB902 and RLB904) following standard proteinase K and phenol chloroform protocols. A segment of 1039 bp including parts of the cytochrome b gene and the threonin t-RNA gene was amplified by PCR (primers: "sicnt-L" 5'-TTTGGATCCCTGTTAGGCCTCTGTT-3' and "H15906" 5'-GGTTTACAAGACCAGTGCTTT-3') and sequenced (primers "sicnt-L" and "HPOD" 5'-GGTGGAATGGGATTTTGTCTG-3') by MWG-BIOTECH (Ebersberg, Germany) sequencing service. A part of the cytochrome b gene consisting of 887 bp was used for analysis. The sequences from both specimens were identical. These were compared with homologous regions from samples collected over most of the native range of *P. muralis* (Schweiger and Mayer, unpubl.). Sequences from individuals from the northern slopes of the Emilian Apennine, from Friuli (Northern Italy), as well as from the Island of Cres in northwestern Croatia were identical to the sequences of the Vancouver Island samples. Because green-colored individuals are common in the Apenninian populations but completely absent in the northern part of the distribution area of this haplotype group, and because green individuals are commonly observed among the BC lizards (Gregory, in litt.), we conclude the founding individuals of the BC population originated in the Emilian Apennine, Italy. Because Common Wall Lizards from there are usually referred to as *Podarcis muralis maculiventris,* we attribute the population on Vancouver Island to this subspecies. This conflicts with Gregory and Gregory (1999. The Reptiles of British Columbia: A Taxonomic Calalogue. Wildlife Bulletin No. B-88, British Columbia Ministry of Environment, Lands and Parks. Victoria, BC), who consider the lizards as *P. m. brueggemanni.*

Sequences were deposited at GenBank under the accession num-

ber AY374256. We thank Patrick T. Gregory for very helpful comments improving the quality of this manuscript, Nadine Bertram for local guidance in West Saanich, and Russell Burke for providing tissue samples from specimens collected by David Cunnington and Kathy Paige.

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: TEXAS: Lee Co. / Burleson Co.: Yegua Creek above Lake Summerville. Collected in March, 2003. Natural History Museum, University of Kansas color slide (KU CT-11922). Verified by John E. Simmons. This specimen was collected in the middle of Yegua Creek. This species has not been previously recorded from Lee County, (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press, College Station, Texas, 421 pp.). Yegua Creek represents the border between the two counties.

Submitted by **WILLIAM B. MONTGOMERY,** P.O. Box 656, Elgin, Texas 78621, USA; e-mail: montgomery6@earthlink.net.

AMPHIESMA SANGUINEA (Smedley's Keelback). MALAYSIA: PENINSULAR MALAYSIA: Johor: Bekok Forest, on forest floor, beside small pool along bank of Sungei Bantang (1°20'N, 103°10'E, ca. 125 m elev.). 7 March 2004. Arvin C. Diesmos. Raffles Museum of Biodiversity Research: Zoological Reference Collection (ZRC) 2.6023. Verified by Kelvin K. P. Lim. Sub-adult (262 mm in total length, 65 mm in tail length), exhibiting diagnostic character of the species (e.g., two preocular scales, instead of one: Tweedie 1983. The Snakes of Malaya, 3rd Edition. Singapore National Printers. 167 pp.). New state record and southerly range extension. Confirmed records of this species have been confined to Cameron Highlands (type locality) and the foothills in Selangor of the peninsula (Tweedie 1983, *op. cit.*).

Submitted by **TZI MING LEONG** (e-mail: scip0132@nus.edu.sg), and **ARVIN C. DIESMOS** (e-mail: g0304912@nus.edu.sg), Department of Biological Sciences, National University of Singapore, Singapore 119260.

BOULENGERINA ANNULATA ANNULATA (Banded Water Cobra). GABON: NGOUNIÉ PROVINCE: Onoy River at Bandi (1°50'S, 11°15'E; 136 m elev.). 19 July 2001. S. Lavoué. Institut Royal des Sciences Naturelles de Belgique (IRSNB 16326). NYANGA PROVINCE: Basse-Banio District, Doumvou River at Doumvou (3°21'S, 10°45'E; 20 m elev.). 25 July 2001. S. Lavoué. Direction de la Faune et de la Chasse, Libreville (DFC; field number P607). Verified by V. Mamonekene. Both specimens collected by fishing nets during an ichthyological survey. New records for the two provinces, making the number of Gabonese provinces having this species seven, i.e., all but Ogooué-Maritime and Haut-Ogooué Provinces (Villiers 1954. Bull. IFAN, sér. A, Sc. nat. 16[3]:1234–1247; Knoepffler 1966. Biol. Gabonica 2[1]:3–23; Blanc and Frétey 2000. Bull. Soc. Zool. France 125[4]:281–292; Pauwels et al. 2002a,b. Bull. Inst. Roy. Sc. Nat. Belg., Biol. 72:47–57, 59–66). The new records are a part of the results of field surveys organized by the WWF Ecoregion Program as a part of its Central Africa Biodiversity Assessment Program. We thank Emile Mamfoumbi Kombila and Marc Mpami (Direction de la Faune et de la Chasse, Libreville) for collecting permits.

CROTALUS RAVUS (Mexican Pygmy Rattlesnake). MÉXICO: HIDALGO: Municipality of Tepeapulco: Texcatzongo, 0.8 km N, 5 km E Tepeapulco (19°47'22"N, 98°30'20"W), 2580 m elev. 21 April and 31 May 1992. A. Hernández. Herpetological Collection of the Escuela Nacional de Ciencias Biológicas (IPN. ENCB 15308–09). Verified by Luis Canseco-Márquez. First vouchered record for Hidalgo and a range extension of ca. 32.4 airline km NE from nearest record at San Juan Teotihuacán, state of México (Gloyd 1940. Spec. Publ. Chicago Acad. Sci. 4:1–266). An unsubstantiated record for this species in Hidalgo was mentioned by Martin Del Campo (1937. Folletos Divulg. Cient. Inst. Biol., México 27:1–18) and depicted on a map in Gloyd (*op. cit.*), a record that presumably was referenced by Smith and Taylor (1945. United States Nat. Mus. Bull. 187:1–239), but Campbell and Armstrong (1979. Herpetologica 35:304–317) found no evidence that it occurred in that state. The two specimens reported here were collected in xerophytic scrub vegetation.

ELAPHE TAENIURA RIDLEYI (Cave Dwelling Ratsnake). THAILAND: PHETCHABURI PROVINCE: Tha Yang District, Kratluang Subdistrict. 18 September 2003. C. Chimsunchart and O. S. G. Pauwels. Institut Royal des Sciences Naturelles de Belgique, Brussels (IRSNB 16681). Verified by Montri Sumontha. This adult male (SVL 1193 mm, tail L 319 mm) was found in a cave on a limestone hill, at ca 150 m from the cave entrance, coiled around a stalactite 3 m above the ground. In another cave, also inhabited by numerous bats, on the same hill and on the same day we caught and released an adult female (TL ca. 1900 mm) that was ca. 7 m from the cave entrance. First provincial record (Pauwels et al. 2003. Nat. Hist. J. Chulalongkorn Univ. 3[1]:23–53). This records extends the known range by about 480 airline km N from the two previous northernmost localities, situated either in the hills of northern Nakhon Si Thammarat Province (Schulz 1996. A Monograph of the Colubrid Snakes of the Genus *Elaphe* Fitzinger. Koeltz Scientific Books, Havlickuv Brod. iii + 439 pp.) or in Phang-Nga Province, without exact locality (voucher Queen Saovabha Memorial Institute, Bangkok [QSMI] 131; Pauwels et al. 2000. Dumerilia 4[2]:123–154). The above mentioned specimens are typical *E. t. ridleyi*, distinct from the other subspecies from Phetchaburi Province mentioned and illustrated by Schulz (*op. cit.*). We thank Chucheep Chimsunchart (Phetchaburi), Alanna Maltby (Imperial College, London), and Edwin Wiek (Khao Look Chang) for their help in the fieldwork.

Submitted by **OLIVIER S. G. PAUWELS**, Department of Recent Vertebrates, Institut Royal des Sciences Naturelles de Belgique, Rue Vautier 29, 1000 Brussels, Belgium (e-mail: osgpauwels@hotmail.com), **PATRICK DAVID**, USM 602 Taxinomie-collection - Reptiles & Amphibiens, Département Systématique & Evolution, Case Postale 30, Muséum National d'Histoire Naturelle, 25 rue Cuvier, F-75231 Paris Cedex 05, France (e-mail: pdavid@mnhn.fr), and **LAWAN CHANHOME**, Queen Saovabha Memorial Institute, Thai Red Cross Society, 1871 Rama IV Rd, Bangkok 10330, Thailand (e-mail: Lawan.C@chula.ac.th).

EUPREPIOPHIS MANDARINUS (Mandarin Ratsnake). VIETNAM: TUYEN QUANG: Na Hang district. March 2003. Photo-

graphed by Le Khac Quyet. Verified by Wolfgang Böhme. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK color slide catalog numbers 0331 – 0333). *Euprepiophis mandarinus* (formerly *Elaphe mandarina*, see Utiger et al. 2002. Russ. J. Herpetol. 9:105–124) was previously known from a few provinces in northern Vietnam (Lai Chau, Lao Cai, Vinh Phu, and Lang Son: Nguyen Van Sang and Ho Thu Cuc 1996. Danh luc bo sat va ech nhai Viet Nam. Nha xuat ban khoa hoc va ky thuat, Ha Noi; Schulz 1996. A Monograph of the Colubrid Snakes of the Genus *Elaphe* Fitzinger. Koeltz Scientific Books, Havlickuv Brod; Gumprecht 2002. Sauria Suppl. Berlin 24: 565–568). The new location in Tuyen Quang Province, northern Vietnam, closes the distribution gap between Lai Chau and Lao Cai in the west, Lang Son in the east and Vinh Phu in the south. The former Vinh Phu Province is currently represented by the provinces of Phu Tho and Vinh Phuc, and the locality Tam Dao, provided by Nguyen and Ho (1996), refers to Vinh Phuc Province. The new finding is located in the northern part of Tuyen Quang Province, more than 100 km N of Tam Dao. This area (Sinh Long commune, Na Hang district) is proposed as an extension of Na Hang Nature Reserve. *Euprepiophis mandarinus* was not previously included in the list of amphibians and reptiles recorded for Na Hang (Boonratana 1998. Na Hang Rainforest Conservation Project. FFI-Indochina Programme, Hanoi).

Submitted by **LE KHAC QUYET**, Fauna & Flora International - Vietnam Programme, IPO Box 78, 55 To Hien Thanh, Hanoi, S. R. Vietnam (e-mail: primates@ffi.org.vn), and **THOMAS ZIEGLER**, Zoologischer Garten Köln, Riehler Str. 173, D-50735 Köln, Germany (e-mail: tziegler@zoo-koeln.de).

LAMPROPELTIS ALTERNA (Gray-banded Kingsnake) MEXICO: NUEVO LEON: Municipio La Fama: Cerro de las Mitras at Gruta Gatos Monteses, 1000 m elev. 2 May 1967. Carlos H. Garcia. Universidad Autonoma de Nuevo Leon Herpetological Collection (UANL 459). Verified by Hobart M. Smith. Municipio Guadalupe: western slope of Cerro de la Silla, ca. 1200 m elev. Caught by unknown local resident. UANL 5018. Verified by Dennis J. Miller. First records for Nuevo Leon and the Sierra Madre Oriental, and a range extension of ca. 75 km ENE and 90 km E, respectively, from near Saltillo, Coahuila (Smith 1941. Copeia 1941:112). Two earlier records of *L. alterna* in Nuevo Leon (Liner 1964. Southwest. Nat. 8:221–227; Liner et al. 1976. Herpetol. Rev. 7:177) were reported in error, as both specimens were actually *Lampropeltis mexicana*, with habitats located in pine-oak associations. The localities reported herein are in the foothills of the Sierra Madre Oriental that contain Chihuahuan Desert vegetation.

NERODIA ERYTHROGASTER FLAVIGASTER (Yellow-bellied Watersnake). USA: ALABAMA: LAMAR CO.: wetland adjacent to Hwy 35, ca. 10.0 km S of junction with U.S. Hwy 78 (34°01'39"N, 88°03'46"W). 14 April 2004. Christopher T. Winne and J. Whitfield Gibbons. Verified by Craig Guyer. Auburn University Museum (AUM 35906). County record. Previously reported in adjacent Marion, Fayette, and Pickens counties (Mount 1975. Reptiles and Amphibians of Alabama. Auburn Printing Company, Auburn, Alabama; Gibbons and Dorcas 2004. North American Watersnakes. A Natural History. University of Oklahoma Press. Norman, Oklahoma). Collection was made under permit 2399 issued to Ken Marion by the state of Alabama Department of Conservation and Natural Resources.

Submitted by **CHRISTOPHER T. WINNE** and **J. WHITFIELD GIBBONS**, University of Georgia, Savannah River Ecology Laboratory, Aiken, South Carolina 29802, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). USA: TEXAS: LEE CO.: CR 316, 2 mi N of FM 696, 10 mi W of Lexington. Hugh Brown Wildlife Sanctuary. Collected in May 2003. Natural History Museum, University of Kansas color slide (KU CT-11921). Verified by John E. Simmons. This species has not been recorded previously from Lee County (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press, College Station, Texas, 421 pp.).

Submitted by **WILLIAM B. MONTGOMERY**, P.O. Box 656, Elgin, Texas 78621, USA; e-mail: montgomery6@earthlink.net.

PORTHIDIUM NASUTUM (Rainforest Hognosed Pitviper). ECUADOR: PROVINCIA DE MANABI: 11 km W of Bahía de Caráquez, on Chone - Sto. Domingo de Los Colorados Road (ca. 00°40'S, 80°23'W, 50 m elev.). 17 July 1991. H. Pedroban and E. Palacios. Laboratorio de Anfibios & Reptiles, Universidad San Francisco de Quito & Fund. G. Orcés (FHGO-USFQ 698). Verified by Jean-Marc Touzet. This species inhabits the humid lowlands of Middle America and adjacent northwestern South America from Chiapas (Mexico) southward to Pichincha (Ecuador) (Porras et al. 1981. Tulane Stud. Zool. Bot. 22:85–107; Schatti and Kramer 1993. Rev. Suisse Zool. 100[2]: 235–278). First province record and the southernmost for the species, extending the range ca. 130 km WSW from closest known localities (surroundings of Santo Domingo de Los Colorados, Pichincha Province, Porras et al., *op. cit.*). Schatti and Kramer (*op. cit.*) erroneously cited the species from Carchi Province based on specimens from "Paramba;" however, this locality is in Imbabura Province (Lynch and Duellman 1997. Univ. Kansas Nat. Hist. Mus. Spec. Publ. 23:1–236).

Submitted by **DIEGO F. CISNEROS-HEREDIA**, Universidad San Francisco de Quito, Ave. Interoceanica y calle Diego de Robles, Campus Cumbaya, Casilla Postal 17-12-841, Quito, Ecuador; e-mail: diegofrancisco_cisneros@yahoo.com.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORDA: BREVARD CO. : West Melbourne, garden at 605 Sugar Pine Drive (28°5'10.1"N, 80°41' 20.4"W). 13 March 2004. Michael S. Grace. Florida Museum of Natural History (UF141405). Verified by K. Krysko. New county record. Found under decaying pine needles, the specimen was 0.7 g body weight and 12.3 cm total length. *Ramphotyphlops braminus* is considered the most geographically widespread reptile on Earth, spread through the trade in potted tropical plants. In the United States, it has been reported as far north as Massachusetts (Wallach et al. 1991. Herpetol. Rev. 22:68) and Virginia (Savitsky et al. 2002, Herpetol. Rev. 33:150), but such northern locales are likely beyond climatic zones where this snake could survive winter conditions and become established. In the southernmost U.S., however, *R. braminus* is almost certainly established. The specimen noted here was found in a garden that had not had plants introduced for at least two years, and represents the northernmost discovery of the species on Florida's Atlantic Coast. In Florida, this snake was reported previously from Key West (Ehrig 1990. Herpetol. Rev. 21:41) and Stock Island (Collins and Collins 2002. J. Kansas Herpetol. 2:11) in the south to as far north as Pinellas County (Crawford and Somma 1993. Herpetol. Rev. 24:68) and Hillsborough County (Hennessy and Michalak 2004. Herpetol. Rev. 35:193) on the western coast, Alachua County in inland Florida (Townsend et al. 2002: Herpetol. Rev. 33:75), and Palm Beach County on the east coast (Delorey and Mushinsky 1987. Herpetol. Rev. 18:56). These records and the new discovery reported here (152 km N of the Palm Beach County location, 88 km SE of nearest known locality in Seminole County; Owen 1998. Herpetol. Rev. 29:115) support the idea that *R. braminus* is is established in tropical and sub-

tropical Florida.

TELESCOPUS FALLAX (Cat Snake). GREECE: EASTERN AEGEAN: Lesvos Island: Vassilika Village. 31 May 2003. Maria Dimaki. Verified by Efstratios D. Valakos. Goulandris Natural History Museum (GNHM 5035). First island record (Dimitropoulos and Ioannidis. 2002. Reptiles of Greece and Cyprus. Goulandris Natural History Museum, 275 pp.).

Submitted by **MARIA DIMAKI**, Department of Terrestrial Zoology, The Goulandris Natural History Museum, 100 Othonos St., Kifissia, Greece; e-mail: mdim@gnhm.gr.

XENOCHROPHIS PUNCTULATUS (Spotted Keelback Water Snake). THAILAND: RANONG PROVINCE: Kraburi District, mangrove surrounding Tham (Cave) Phrakhayang. 18 May 2003. M. Sumontha. Queen Saovabha Memorial Institute, Bangkok (QSMI 767). This adult female (SVL 465 mm, tail L 165 mm) was found at 0035 h asleep on a mangrove palm tree 20 cm above high tide level. Verified by Lawan Chanhome (QSMI). Another adult female had been previously observed in the same locality on 5 December 2002, while it was swimming at 1500 h in brackish water between mangrove palm trees. Other snake species found in syntopy include *Cerberus rynchops*, *Enhydris plumbea*, *Fordonia leucobalia*, *Bungarus fasciatus*, and *Trimeresurus purpureomaculatus*. These records represent the first for the province and the second for the country, and a 660 km range extension southwards for the species from its former southernmost locality in southern Myanmar (Pauwels et al. 2001, Hamadryad 26[2]:259–264).

e-mail: rcalderon@ecosur-qroo.mx

During the course of fieldwork on amphibians and reptiles, between March and November 2002, on the Sian Ka'an Biosphere Reserve and adjacent areas of Quintana Roo, México, three new state records and eight significant range extensions were recorded. All specimens were collected by the authors and deposited in the Herpetological Collection of the Museum of Zoology, Colegio de la Frontera Sur, Chetumal, Quintana Roo, México (ECO-CH-H). All species were verified by Oscar Flores-Villela. The new distributional records are based on Campbell (1998), Calderon et al. (2003), Cedeño-Vaquez et al. (2003), Köhler (2000), and Lee (1996).

New State Records

Gastrophryne elegans (Elegant Narrowmouth Toad). 50 km S, 15 km E of Felipe Carrillo Puerto (19°08'16.3'N, 88°02'49.7"W). 27 May 2002. ECO-CH-H-1935, 1911. This new state record is from about 135 km NW of the closest reported locality on Albion Island, Orange Walk, Belize.

Ctenosaura defensor (Yucatan Spinytail Iguana). 3 km E of Santa Teresa Station (19°44'03"N, 87°47'46.7"W). 23 April 2002. ECO-CH-H 1782. Based on Kohler (2000) and Cedeño-Vazquez et al. (2003), this is the first record for Quintana Roo, and extends the known range ca. 200 km NE from the closest reported locality at Dzibalchen, Campeche.

Norops biporcatus (Neotropical Green Anole). 17 km SE of Andrés, Quintana Roo (19°08'51.3"N, 88°02'24.7"W). 28 September 2002. ECHO-CH-H-2022. This new state record is from ca. 150 km NNW of the closest locality within the Calakmul Biosphere Reserve, Campeche. The specimen was found in secondary semideciduous forest.

Range Extensions

Eleutherodactylus yucatanensis (Yucatan Rainfrog). 3 km E of checkpoint entrance on road to Sian ka' Biosphere Reserve (19°08'51.3"N, 88°02'24.7"W). 28 July 2002. ECO-CH-H 1883, 1909, 1949). Zascabera, 7 km E of Santa Teresa Station (19°45'29.3"N, 87°45'58.1"W). 28 July and 2 August 2002. ECO-CH – H 1883, 1909, 1932. 50 km S, 16 km E of Felipe Carrillo Puerto (19°08'08"N, 88°02'34.7"W). 27 September 2002. ECO-CH-H 2014-16. Breach Pemex (19°13'26.7"N, 88°01'32.6"W). 2 October 2002. ECO-CH-H 2042. These records extend the range of the species ca. 70 km S of the nearest record from 25 km NE of Felipe Carrillo Puerto. All the specimens were collected on bushes, branches, and tree trunks, which are in contrast to Lee's (1996) account that this poorly known species is a ground dweller.

Sphaerodactylus glaucus (Dwarf Gecko). Pulticup (19°05'22.3"N, 87°33'06.4"W). 3 June 2002. ECO-CH-1912, 1941. These records close the distributional gap between previously reported specimens in the northern and southern ends of Quintana Roo.

Hemidactylus frenatus (Common House Gecko). Pulticup (19°05'22.3"N, 87°33'06.4"W). 3 June and 5 October 2002. ECO-CH-H 1933, 2046). The records are a ca. 150 km range extension from the nearest known locality at Punta Chiqeros, on Cozumel Island (Lee 1996).

Thecadactylus rapicauda (Turniptail Gecko). Near checkpoint at entrance to Sian ka' Biosphere Reserve, 48 km N of Felipe Carrillo Puerto (19°55'46"N, 87°46'57.3"W). 30 April 2002. ECO-CH-H 1965. Ponud road to Cafetal (19°06'48.3"N, 88°03'19.3"W). 28 September 2002. ECO-CH-H 2019. These records close a distributional gap between the closest reported localities on the northern (ca. 50 km N in Quintana Roo) and southern (ca. 200 km S in Belize) portions of the Yucatán Peninsula.

Sceloporus lundelli (Lundell's Spiny Lizard). Santa Teresa Station (19°44'37.6"N, 87°47'01.1"W). 24 April and 27 June 2002. ECO-CH-H 1818, 1839, 1961. These specimens represent the third locality for the species in Quintana Roo and extend the range ca. 120 km N of the closest locality at Bahía de Chetumal (Cedeño-Vásquez et al. 2003).

Eumeces sumichrasti (Sumichrast's Skink). 50 km E of Felipe Carrillo Puerto, on road to Playon (19°47'19.3"N, 87°37'42.2"W). 26 April 2002). ECO-CH-H 1850. 50 km S, 16 km E of Felipe Carrillo Puerto (19°08'08"N, 88°02'34.7"W). 27 May 2002. ECO-CH-H 1913. These records bridge a distributional gap between previously perceived disjunct populations of this species on the northeastern (100 km extension SW) and southern parts (200 km extension N) of the Yucatán Peninsula as depicted by Lee (1996).

Mabuya unimarginata (Central American Mabuya). Playon (19°49'17.4"N, 87°29'40.1"W). 1 August 2002. ECO-CH-H 1968. This record bridges the gap between the documented populations on the northern, western, and southern portions of the Yucatán Peninsula.

Aspidoscelis cozumelae (Cozumel Racerunner). Pulticup (19°05'22.3"N, 87°33'06.4"W). 5 October 2002. ECO-CH-H 2047. Dunes in front of Mosquitero Lagoon (19°12'27.8"N, 87°32'17.1"W). 4 June 2002. ECO-CH-H 1871. This record extends the range of this species on the mainland ca. 80 km N of the closest locality in southern Quintana Roo at Lake Bacalar (LSUMZ 33387). It is also known from northeastern Quintana Roo on Isla Cozumel and Isla Mujeres.

Acknowledgments.—We are indebted to Oscar Flores-Villela for verifying specimen identifications and for helpful comments on an earlier version of this manuscript. We are grateful to Alejandro Tuz, Alejandro Franco, and the staff of the Sian ka' Biosphere Reserve.

Smilisca baudinii (Duméril et Bibron, 1841) is a widely distributed hylid frog, ranging from Costa Rica (Savage 2002) to the border between Texas and Mexico (Duellman 2001). The species is present along a broad altitudinal range from the Pacific Coast up to elevations of 2000 m in cloud forests (Duellman 2001). Its distribution in Mexico covers a wide area from Chiapas and Yucatán (Lee 1996) to Tamaulipas and southern Sonora (Duellman 2001) including the Isla María Madre (Tres Marías Islands) along the coast of Nayarit (Casas-Andreu 1990, 1992). It has not been recorded from the Baja California peninsula (Grismer 2002; Grismer and McGuire 1993; McPeak 2000).

During a field trip along the Baja California peninsula on 13 April 2003 we found two active specimens of *Smilisca baudinii* in a flooded grass field among palm trees near the village of Todos Santos (Baja California Sur, México) (23°27'N, 110°13'W, 28 m above sea level). The two specimens were found at night (collectors: ER-G, IM-S, GP-O and MG-P), jumping on the flooded grass, around 2130 h, in company of active *Bufo punctatus*. There was no sign of reproductive activity of either species. One specimen of *Leptotyphlops humilis* was found under stones in the drier area of the field, and *Hemidactylus frenatus* was present in nearby buildings. The two specimens of *S. baudinii* (IBH 14078–79) have been deposited in the CNAR collection (UNAM, México).

Smilisca baudinii aggregates in large numbers during the breeding season (Duellman 2001), and accidental transport from any of the ferry ports near which the species occurs seems possible. Alternately, this population might represent an old relict isolated from the main distribution range of the species. The presence of *S. baudinii* in Tres Marías Islands (Casas-Andreu 1990), apparently isolated from the continent since the Middle Pliocene (Casas-Andreu 1992), does not shed light on this issue, as both possibilities are equally plausible. Molecular studies to detect the precise origins of these populations are underway.

Acknowledgments.—This research profited from the resources of a UCMexus-CONACyT Collaborative grant number CN-02-74 to G. Parra-Olea. Iñigo Martínez-Solano was supported by a CSIC-UNAM travel grant.

This book is a collection of papers constituting the proceedings of a symposium on Multiple Stressor Effects in Relation to Declining Amphibian Populations held 16–17 April 2002 in Pittsburgh, Pennsylvania and sponsored by the American Society for Testing and Materials (ASTM) International. The three main goals of the symposium, as stated in the published proceedings, are: 1) To highlight the historic role that the ASTM has in providing a forum for standardization of amphibian toxicity test methods and the characterization of adverse effects potentially associated with chemical stressors, 2) to demonstrate, via case studies, the current state of technical 'tools' available to biologists, ecologists, environmental scientists, and natural resources professionals for assessing amphibian populations exposed to various environmental stressors, and 3) to characterize a process that brings together a range of interdisciplinary technical and management tools to causal analysis, especially those that related to a multiple stressor risk assessment "mind-set". I think the book achieves these stated goals.

The book is divided into three sections, reflecting the major themes of the symposium: 1) toxicity assessment, 2) field and lab studies, and 3) causal analysis. The toxicity section consists of three chapters mostly focused on the development and use of toxicity tests for amphibians. These include FETAX (Frog Embryo Teratogenesis Assay-*Xenopus*) to assess developmental effects of potential teratogens, and the somewhat competing Amphitox, a toxicity test using *Bufo* embryos. Each of these approaches has advantages and disadvantages. Overall, this section was very convincing in demonstrating teratogenetic/toxicological assay methods that require relatively little technical expertise. As a developmental biologist familiar with the vagaries of amphibian development, however, I am a little leery of such standardized tests. The validity of the FETAX method in particular has recently been questioned because of the sensitivity of amphibian embryos to variation in essential cations (Tietge et al. 2000).

The section on field and laboratory studies includes nine chapters that get down to the nitty-gritty of real data collected from the field and/or laboratory. I was particularly interested in a chapter on frog abnormalities in National Wildlife refuges in the Northeastern US by Eaton-Poole et al. This study seemed to be a rigorous example of how to go about trying to understand abnormalities in natural populations of amphibians, a good model for future studies. The authors report an analysis of over 3643 frogs and toads over a three-year period from a total of 35 sites, representing a tremendous amount of work. The objectives of this study were to 1) identify "hotspots" where high levels of abnormalities occur, 2) determine the temporal patterns of occurrence of abnormalities at those spots, and 3) try to pinpoint possible causes. Visual assessment using x-ray radiographs was used to score and classify abnormalities into one of five possible categories: malformation, trauma, infectious disease, nutritional deficiency, and "unknown." The abnormal specimens were also used to identify viral, fungal, or parasitic infection using visual inspection, dissection, tissue culture, and/or histology. The prevalence of abnormalities ranged from zero to approximately 15% and was highly variable from year to year and site to site. As in many other such studies, the most common abnormality observed was frogs with a partially or completely missing hind limb, and supernumerary limbs were relatively rare. The study demonstrated the importance of radiographs in detecting internal abnormalities that are misdiagnosed or not detected at all by superficial examination. In trying to pinpoint causes in a sample of 89 abnormal frogs, 62% had abnormalities apparently caused by trauma, and 25% were judged to carry "true malformations." Cyst infection by trematodes of the genus *Ribeiroia* is the only firmly established cause of limb deformities/malformation in natural populations of frogs (Johnson et al. 1999; Sessions et al. 1999; Stopper et al. 2002). Recognizing this, the authors took special pains to try to eliminate *Ribeiroia* as the cause of abnormalities in their frogs. Consistent with other studies (e.g., Meteyer et al. 2000), *Ribeiroia* cysts were not found at every hotspot, but when they were, they were associated with supernumerary limb structures. The authors correctly conclude that an investigation into possible causes of abnormalities in natural populations of amphibians probably requires an integrated, interdisciplinary approach including surveys, experimental exposures, radiography, microbiology, parasitology, endocrinology, immunology, and toxicity analyses, to name a few.

The last section, Causal Analysis, contains four chapters and, in my opinion, is the most important part of the book. Here we find a series of papers illustrating the range of tools currently available for evaluating cause and effect relationships between environmental stressors and declining and deformed amphibian populations. Emphasis is on identifying the kind of research needed to find solutions for these problems. My own research interests led me to focus particular attention on the chapter by Lanoo et al. on "Multiple Causes for the Malformed Frog Phenomenon." Malformed/deformed frogs is a contentious issue that has been well-publi-

cized in the media (including the internet), and some have considered it a "scientific nightmare." Even the terms "malformation" and "deformation" are loaded with controversy! The medical definition of malformation is "an abnormality of structure resulting from an *intrinsic* defect in the formation of that structure [my italics]," while a deformity is defined as "variation in structure resulting from the response of normal tissues to mechanical forces" (Winter et al. 1988). I have come to learn that people who believe that the frog abnormalities may be caused by chemical pollutants tend to describe the abnormalities as malformations, since the pollutants, acting as teratogens, are likely to interfere in cellular interactions at the molecular level. On the other hand, those who work on parasite-induced abnormalities tend to call them deformities, since the mechanical effects of cysts have been shown to be sufficient to cause the specific limb deformities (Sessions and Ruth 1990; Stopper et al. 2002). For this reason, I find it wise to side-step the issue and simply use the term "abnormalities".

Although the "abnormal frog phenomenon" encompasses a wide range of different kinds of morphological abnormalities, the vast majority of cases involve the limbs (mostly the hind limbs). These limb abnormalities fall into two major categories (or "syndromes"): 1) frogs with too many limbs (and a host of associated gross abnormalities, such as mirror-image duplications, truncated limbs, and badly distorted limbs) and 2) frogs with too few limbs (usually a completely or partially missing hind limb or foot). Category 1 abnormalities are now known to be directly caused by infection by *Ribeiroia* cysts but the cause of category 2 deformities remains uncertain, although predation has been implicated in some studies, and heavy parasite infection can also cause limblessness (Sessions and Ruth 1990; Sessions et al. 1999; Stopper et al. 2002). Multilegged category 1 frogs were used early on as the "poster child" for the entire "malformed frogs" issue and, once the parasite connection was established, this caused some confusion and (in my opinion) wasted effort. As of this writing, parasites (*Ribeiroia* sp) remain the only documented cause of supernumerary limbs in natural populations of frogs (Blaustein and Johnson 2003; Sessions 2003). Likewise, the evidence presented in this chapter points to parasites as the only identified cause of any of the morphological abnormalities, although the absence of parasites from some of the "hotspots" indicates that something else may be going on at those sites. Unfortunately, our knowledge of *Ribeiroia* natural history is still very rudimentary.

I was a little dismayed that this chapter still mentions retinoids as a possible cause for limb abnormalities in frogs even though there is little or no evidence (and at best only very weak theoretical basis) that retinoids are playing a role in any of the naturally occurring morphological abnormalities (Sessions 2003). Morphological evidence excluding retinoids as a cause of limb abnormalities in natural populations of frogs was presented by Sessions et al. (1999), but this paper was not cited by the authors (even though they discuss the problem of inferring cause from morphological pattern!). The morphological consequences of retinoid exposure to limb development and regeneration in frogs have been very thoroughly studied and characterized, and neither the observed abnormalities nor the required (high) retinoid concentrations fit what is observed in nature. I suppose one could argue that examining the possible role of retinoids is nevertheless worthwhile since it is difficult to imagine a more serious environmental catastrophe, if ground water at hotspots contains enough retinoids to cause limb malformations in frogs (and certainly a considerable amount of money has been thrown at the problem), but it's probably time to get realistic and move on.

Probably the most useful conclusion from this chapter is that hotspots of frogs showing abnormalities are usually associated with altered wetlands, suggesting that a good approach to solving the problem should involve restoration of these ecosystems. A particularly likely scenario is that cultural eutrophication of wetlands encourages increases in snail populations which in turn provide an expanded substrate for parasites, since they serve as the first intermediate host (Sessions 2003). Since trematodes undergo a kind of "embryonic amplification" in snails, whereby a single egg can give rise to hundreds if not thousands of infectious cercariae (Noble and Noble 1982), small changes in the snail population could have very large impacts on the production of cercariae in a particular pond (Sessions and Ruth 1990; Stopper et al. 2002; Sessions 2003). I was a little surprised, however, that the authors did not spend more time examining another component of parasite-caused deformities, namely birds, which serve as the primary host in the trematode's life cycle (Pratt and McCauley 1961). Birds could be a primary determiner of the unusual distribution of *Ribeiroia*-infected snails in Minnesota.

One of the big take-home messages from this collection of papers is that if we want to understand amphibian declines and deformities, we need to examine multiple stressors. This may be true, and is certainly not a novel conclusion (cf. Semlitsch 2003), but it does beg the question: is there ever a case of amphibian decline or abnormalities that has been caused by just a single major stressor? For example, if someone emptied a barrel of pesticide into a pond, or if over-collecting depleted the population. Or, similarly, are there single stressors whose presence allows us to exclude others? For example, if small organisms (such as free-swimming cercariae) are more vulnerable to toxic chemical pollutants than larger organisms, then finding that parasites are associated with deformed amphibians at a particular site may allow one to exclude the presence of toxic chemicals (I call this the "perverse hypothesis"). This possibility needs to be tested. Overall, although it makes intuitive sense that chemical pollution is contributing to amphibian decline and deformities, and some effects can be demonstrated experimentally, there is surprisingly little evidence of this being a major cause, especially in regard to deformed amphibians. Perhaps this will change as the intensity of research increases. Despite the price of the book which, at $109.00, seems a little high, it is the best symposium volume on this topic that I have seen, and anyone interested in the problem of declining and deformed amphibians will want to have it on their bookshelf.

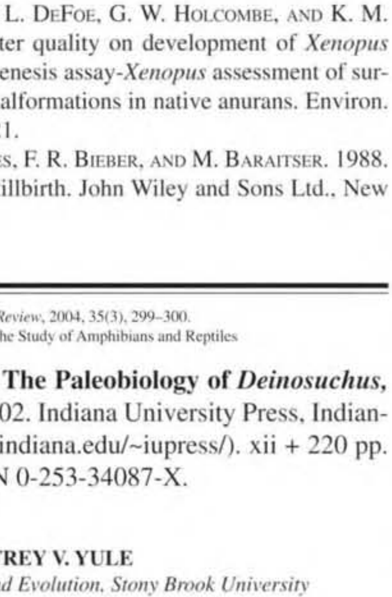
e-mail: jyule@life.bio.sunysb.edu



David R. Schwimmer's preface promises a paleoautoecology of *Deinosuchus rugosus*—that is, a study of the life, times, and habitat of what was probably the largest land carnivore of late Cretaceous North America and is certainly the continent's largest known crocodylian. The project is broad in scope, engaging, and successful — even admirable. In addition to offering an overview of the coastal plains of the Western Interior Seaway that *Deinosuchus* inhabited, Schwimmer also contextualizes current knowledge of the species while carefully interpreting fossil evidence, taking care to point out which of his conclusions are well corroborated and which are more speculative. The analysis is impressive and demonstrates just how much we can infer about vanished species and ecosystems on the basis of fairly undramatic fossil evidence.

And make no mistake: the fossil evidence on which Schwimmer relies is not dramatic. While other vertebrate paleontologists seeking to reconstruct the lives and habitats of extinct North American species have access to abundant materials, Schwimmer must rely on a very limited array of specimens. Fossil remains of *Deinosuchus* consist of skulls, jaws, teeth, and a variety of postcranial bones but, so far, no substantially complete individuals. Because the fossils that have been found indicate that *Deinosuchus* was generally typical of eusuchians (i.e., those derived lineages that include all modern crocodylians), Schwimmer reconstructs missing elements based on eusuchian models. Consistently, though, Schwimmer specifies when he bases his reconstructions, or his conclusions, on best guesses rather than actual *Deinosuchus* remains. Fossils bearing likely evidence of *Deinosuchus* predation also prove helpful in Schwimmer's effort to ascertain the crocodylian's diet. Here, too, Schwimmer carefully differentiates between informed, evidence-based speculation and hunches.

The study's tone is conversational but not at the expense of necessary detail, whether offering context on broad topics (e.g., taxonomy, anatomy, paleontological methods) or elaboration within particular subtopics (e.g., crocodylian taxonomy and anatomy, methods for estimating the size of *Deinosuchus*). Chapter 1, "The Life and Times of a Giant Crocodylian," opens with a hypothetical predation event by a *Deinosuchus* on a 600-kilogram, 6-meter long theropod along with a preliminary overview of the animal's habitat along the southern coast of the Western Interior Seaway, a body of salt water that bisected the North American landmass during the Cretaceous. Schwimmer's discussion of the crocodylian is clear, concise, and thorough, as is his coverage of the animal's habitat, both briefly here and at greater length in Chapter 5, "*Deinosuchus* Localities and Their Ancient Environments." The paleoecological groundwork Schwimmer provides is surprisingly thorough, carefully chosen, and very clearly presented, with the result that readers develop an appreciation for an extensive coastal habitat of a sort that no longer exists. While Schwimmer returns at greater length to the subject of what *Deinosuchus* preyed upon (both dinosaurs and turtles) in Chapter 8, he first devotes chapters to the early paleontology of the species, offering an historical overview of its discovery and the confusion surrounding its generic and species names (Chapter 2) and discussions of the techniques used to determine the animal's size (Chapter 3) and the age during which it lived (Chapter 4). Schwimmer's thorough treatment of the animal also tackles the question of how many species of *Deinosuchus* existed (Chapter 6), concluding that despite the wide range in sizes between eastern and western specimens, only one species occurred on both sides of the Western Interior Seaway. Before returning to the subject of the animal's diet, Schwimmer provides a primer on crocodylian taxonomy and the place of *Deinosuchus* in that taxonomy (Chapter 7). Additional background and context are provided in three appendices: one on the details of the geologic time scale (including subdivisions of the late Cretaceous); the second a glossary of anatomical and cladistic terminology; and the third a list of known *Deinosuchus* localities including details about the materials collected at each location. Throughout, Schwimmer makes thorough use of available evi-

dence while recognizing that new fossil finds and recently recovered materials currently under preparation might well support different conclusions.

The result is an in-depth introduction to a species whose largest known representatives were roughly 12 meters in length and at least 8.5 tons in weight. By way of context, that would have made them at least as large as their dinosaur contemporaries and capable of hunting both dinosaurs and any other species in their range —except, possibly, for the larger mosasaurs, plesiosaurs, and pliosaurs. Schwimmer estimates that, in life, even the smaller eastern *Deinosuchus* specimens would have been 8.0 meters long and about 2.3 tons in weight—far larger and more massive than any contemporary crocodylians. While the first and last chapters emphasize the size of the animal and the likelihood that it preyed upon dinosaurs, quite clearly with the intention of attracting readers, *King of the Crocodylians* offers far more substance than sensationalism, and the ecological and evolutionary context Schwimmer provides allows readers to appreciate both *Deinosuchus* and, through their contrast with it, its extant cousins.

The study's main shortcoming, the low quality of a few of its illustrations, is minor. Most of Ron Hirzel's line drawings are at least effective in revealing necessary information about the crocodylian's anatomy and appearance, and a few are exceptionally well rendered (e.g., the *Deinosuchus* pursuing a marine turtle in Figure 8.1). In some instances, probably because of the relatively small size at which fairly large illustrations are reproduced, the thickness and abundance of lines result in images whose individual elements are difficult to resolve. This is true of Figure 8.4, where the play of line and shadow makes it difficult to determine how the jaws and teeth of the pictured *Deinosuchus* are closing on a turtle. A few photographs also reproduce poorly, particularly those of South American museum specimens, tending to be out of focus, dark, or both. The shortcoming is certainly not significant given the study's many strengths, but it is regrettable.

This engaging study is a popularization in the most positive sense of that term—and a rigorous one at that. Schwimmer does not dispense with discussions of anatomical and taxonomic detail; instead, he covers all the relevant ground, taking care to explain the terminology as he goes. The result is admirable: a study that will be of interest and value to many students of herpetology, paleontology, and natural history — and, quite possibly, a welcome addition to courses in herpetology, paleontology, or paleoecology, where it could serve as an excellent case study of the methods used in making inferences about extinct creatures and their environments. Interested readers, and there will be many, will appreciate and benefit from the volume's thoughtfulness, thoroughness, and accessible tone.

PUBLICATIONS RECEIVED

Atlas Plazów I Gadów Polski, Status – Rozmieszczenie – Ochrona (Atlas of the Amphibians and Reptiles of Poland, Status – Distribution – Conservation), edited by Zbigniew Glowacinski and Jan Rafinski. 2003. Biblioteka Monitoringu Srodowiska, Warszawa – Kraków, Poland. 152 pp., 4 pls. Softcover. Distributed free. ISBN 83-7217-208-0.

This volume provides up-to-date information about the distribution and conservation status of the 18 species of amphibians and nine species of reptiles inhabiting Poland. The distribution of each species is plotted, in color, in cells of approximately 100 km^2 on grid maps of Poland, providing a fine scale picture of species ranges. These differentially plot historical records, introductions, and questionable localities. For each species a text overview of distribution pattern and population status is provided (in Polish with an English summary) as is a list of sources of the plotted records. Short sections in Polish cover hybridization and taxonomic problems as well as conservation and protection of the Polish herpetofauna. A comprehensive bibliography of more than 750 references, including many unpublished theses and reports, is also provided, as are keys (in Polish and English) to the amphibians and reptiles of the country. The book concludes with four pages of color plates illustrating 11 of the species covered as well as several habitats. It will be of particular interest to those working on the European herpetofauna or interested in the conservation biology or biogeography of temperate herpetofaunas.

Predicting Extinction: Fundamental Flaws in IUCN's Red List System, Exemplified by the Case of Sea Turtles, by N. Mrosovsky. 2004. N. Mrosovsky, Toronto, Canada (available from the author: Department of Zoology, University of Toronto, Toronto, Ontario, Canada M5S 3G5). [4] + 70 pp. Softcover. ISBN 0-9734777-0-9.

This small book is the hard copy version of an earlier (2003) electronic document (http://members.seaturtle.org/mrosovsky/) outlining the author's arguments regarding the inappropriateness of current IUCN Red List categories for certain long-lived and widespread species, such as sea turtles. Mrosovsky raises concerns about a number of problems including: inconsistencies in the application of IUCN criteria, the assignment of Red List status based on strict application of IUCN criteria even when contradicted by common sense, and the primacy of precautionary approaches over evidentiary ones in the designation of IUCN categories. Evidence is presented that the status of green, hawksbill, olive ridley, and leatherback turtle populations is better than is reflected by current IUCN listings for these species. Suggestions for improvements to the existing system of assessing risks of extinction are provided. The arguments presented are supported by a reference list of 80 citations. This publication is of direct relevance to both sea turtle biologists and those more broadly involved with the assessment of conservation status of reptiles and amphibians.

Venomous Snakes of North Carolina, by Alvin L. Braswell, William M. Palmer, and Jeffrey C. Beane. North Carolina State Museum of Natural Sciences, 11 West Jones Street, Raleigh, North Carolina 27601, USA (also available free in electronic format at www.naturalsciences.org/research/herpetology/Venomous_Snakes_of_NC.pdf). 31 pp. Softcover. US $3.00. ISBN 0-917134-24-9.

This booklet is a basic guide to the six species of venomous snakes inhabiting North Carolina. It includes a short introduction, followed by an illustrated key to species, and a series of species accounts, each occupying two pages. The accounts include a short, non-technical description, natural history notes, and a section on distribution in North Carolina. Accounts also include a point locality county map of North Carolina and one or two color photos. A "Resources" section at the end of the accounts guides readers to selected books and websites, as well as seven sources cited in the text. One page is devoted to "Snake Safety," which provides advice on how to avoid being bitten by venomous snakes, and another alerts readers to the several options for animal identification provided by the North Carolina State Museum of Natural Sciences. The back cover outlines basic snakebite treatment as recommended by the Carolinas Poison Center. This small guide will be especially useful for amateur naturalists and visitors to North Carolina who want to be able to identify (and possibly avoid) the snakes they encounter.

Introducción a los Anfibios y Reptiles del Estado de Chihuahua/ Introduction to the Amphibians and Reptiles of the Stae of Chihuahua, Mexico, by Julio A. Lemos Espinal, Hobart M. Smith, and David Chiszar. 2004. Universidad Nacional Autónoma de México and Comisión Nacional para el Conocimiento y Uso de la Biodiversidad – México D.F., México (distributed by Bibliomania!, P.O. Box 58355, Salt Lake City, Utah 84158-0355; www.herplit.com). [7] + 128 pp. Softcover. US $24.95. ISBN 970-9000-21-7.

This book provides an overview, in both Spanish and English, of the herpetofauna of Mexico's largest northern state and represents a summary of an ongoing project by the authors. A short history of herpetological exploration in Chihuahua is given and a list of the 186 taxa of Chihuahuan amphibians and reptiles (including six new species and 14 new state taxon records documented since 1995) and their general distributions within the state is presented. The bulk of the volume comprises identically illustrated Spanish and English keys to the species and subspecies. A key to the genera of anuran larvae is also provided. The illustrations accompanying the keys are derived from a number of older sources and vary in their style and quality. Many of the species are also depicted in series of 136 small color photographs distributed on 23 pages separating the two different language sections of the book. A literature cited section of approximately 300 references completes the volume, which will be of greatest utility to herpetologists working in northern Mexico and the adjacent areas of west Texas and New Mexico.

Fauna of the Socotra Archipelago – Field Guide, by Wolfgang Wranik, with contributions by Omar Al-Saghier, Simon Aspinall, Richard Porter, and Herbert Rösler. 2004. Universität Rostock, Universitätsdruckerei Rostock, Zum Laakkanal 20, D-18109 Rostock, Germany (e-mail: uni-druckerei@verwaltung.uni-rostock.de). 542 pp. Hardcover. ¤79.00 (approx. US $96). ISBN 3-86009-263-4.

This large volume is the first comprehensive treatment of the Socotran Archipelago, the series of four islands belonging to the Republic of Yemen and lying east of the Horn of Africa and south of the Arabian Peninsula. Socotra has long been known for its high number of endemic taxa (especially plants) and its role as a biogeographic enigma. The book covers the terrestrial fauna in detail and marine forms rather superficially. Of interest to herpetologists are background chapters on the geology, biogeography, vegetation, and climate of the islands, as well as reviews of conservation on Sokotra and the history of biological exploration there. The reptile chapter (there are no amphibians), authored by Rösler and Wranik, covers the 32 species (21 lizards, 1 amphisbaenian, 6 snakes, 4 marine turtles) in 31 pages of text and line drawings plus 30 pages of color plates with more than 110 large format images. Basic identifying features, distribution, and natural history information are provided for each species. The book concludes with a section on animal names in Socotri, a glossary, literature cited, and an index. While few herpetologists may actually visit Socotra, this volume will appeal more broadly to those with an interest in the fauna of Africa, the Middle East, or the Palearctic region, or in biogeography in general.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.html>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information below) or from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Peabody Museum of Natural History, Yale University, P.O. Box 208118, New Haven, Connecticut 06520-8118, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Dr. Theodora Pinou, SSAR Treasurer, Western Connecticut State University, Department of Biological & Environmental Sciences, 181 White Street, Danbury, Connecticut 06810, USA. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6

BOOK REVIEWS

ods. That afternoon the trap was moved and set at another nest site. When checked on the morning of 1 August 2002, the water was calm and clear and the bait appeared minimally disturbed. When we began to pull up the anchoring stakes, we realized the trap contained a female alligator with a total length of 248.9 cm.

The trap was not set again until 7 August 2002, at a new nest site. When checked on 8 August, we found the bait had fallen off the suspending cable. It was rebaited and checked the next day. The door had fallen closed (perhaps bumped by the alligator or as a result of gusty winds), and the bait appeared untouched. The trap was moved and next set on 21 August 2002. The female was observed when placing the trap at the nest site, and despite minor disturbance (photography) for some 20 minutes, the female (201.9 cm) was captured overnight, again caught apparently without injury.

The trap was moved to a new nest site on a floating marsh, with an unstable foundation. When checked on 23 August we found it had fallen over slightly sideways, having been inadequately anchored into position on the unstable marsh or bumped by the alligator at the site. This was the final opportunity to test the trap for this nesting season.

Of note, in Joanen's study (1969) of alligator nesting, data from movement recorders placed at four nests indicated over half of 66 nest visits recorded occurred in the first three weeks of incubation (approximately mid-June through first week of July). Nest visits were rare until the ninth/final week of incubation in late August, when 27.3% of nest visits occurred (Joanen 1969). We believe our trap was very successful, in that the first two alligators were captured during the 6th-7th week of incubation, when only one nest visit of 66 was noted in the four nests Joanen (1969) monitored.

We also measured plasma corticosterone levels from the blood sample we took after removing the alligators from the trap. These measured 5.07, 5.03, and 3.29 ng/ml for the three alligators captured. The second alligator trapped (for which we were unable to check the trap until the second day after it was set) had no higher stress hormone level than the first one, caught and bled the next day after the trap was set. We do not know however when the alligator entered the trap after it was set. For comparison, five adult alligators bled immediately upon capture had average plasma corticosterone levels of 0.8 ng/ml, which rose to an average of 12.6 ng/ml after four hours of restraint stress (Elsey et al. 1991). The slightly elevated corticosterone levels in our trapped alligators may have resulted from being contained within the trap, or due to the acute stress of being removed from the trap prior to blood sampling. It took ca. 10–15 minutes to remove the anchoring stakes, move the trap to a relatively dry spot in the marsh (Fig. 2), remove the alligator from the cage, secure the jaws, and obtain the blood sample. Our normal procedure of snaring aggressive females generally takes about 5 minutes from initiation of capture until the blood sample is obtained.

We believe this prototype trap was very successful in our limited testing. In every case when we caught an alligator, the alligator was extremely calm resting on the bottom beneath the water, and did not appear to have struggled within the trap. This trap is advantageous in that it allows for capture of wary adults, and although preferred, does not have to be checked on a daily basis as the alligator does not have a snare around its neck (possibly causing injury/drowning). Trapped alligators are also protected from fighting/cannibalism from other alligators that might attack an alligator caught in a "walk-in" snare system. The trap could be very useful in situations where nuisance alligators need to be live captured and removed, as it may be socially problematic to harvest the alligator in question. We also did not capture any non-target species. A disadvantage is hormone analyses may be altered due to restraint time/mild stress effects (Elsey et al. 1991), as we prefer to collect blood samples immediately after capture, with minimal disturbance.

FIG. 2. Captured alligator (201.9 cm total length) within trap, being moved to high ground for processing. Note door in closed position and trap transported with reasonable ease by two persons.

Improvements could be made by designing an easier way to remove a captured alligator from the trap (we had to open the door, noose the alligator by the neck, and physically pull it out of the entrance). Also, if large male alligators are targeted, the trap may need to be enlarged.

Acknowledgments.—We thank Randy Broussard, Jimmy Hartobey, Dwayne LeJeune, Eric Richard, and John Turner for assistance in construction and field testing of the trap. We acknowledge Karen McCall for assistance with preparation of the manuscript. We thank Val Lance for plasma corticosterone analyses.

The Western Toad (*Bufo boreas*) has undergone severe reductions in population sizes and distribution in much of its geographic range (Carey 1993; Colorado Division of Wildlife 1997; Corn et al. 1989; Livo and Yeakley 1997). In the southern Rocky Mountains, which include portions of the states of Colorado, Wyoming, and New Mexico, *B. boreas* is a candidate species for federal listing under the United States Endangered Species Act. Federal listing is "warranted but precluded," however, because there are other species presently in greater need (Federal Register 2002). Because of declining populations, the states of New Mexico and Colorado listed *B. boreas* as endangered in 1976 and 1993, respectively (Colorado Division of Wildlife 1997). In Utah, *B. boreas* is considered a species of special concern because of declining populations (State of Utah Rule R657-48) and lack of knowledge on current distribution (Ross et al. 1995).

Only 70 *B. boreas* localities were documented in Utah prior to 1995 (Fig. 1). These localities were based on museum records, various databases, and survey efforts, however, it was not known how many historical sites still supported *B. boreas* or how well these sites represented the distribution of the species in the State of Utah. Ross et al. (1995) reported that the majority of the historical records for *B. boreas* in Utah were concentrated in northern Utah and a large number of these locations were in the Wasatch Mountains between Salt Lake City and Provo (Fig. 1). This distribution pattern may reflect increased survey effort in this part of the state. Between 1980 and 1994, *B. boreas* records were scattered and typically consisted of the presence of one to several adults. Twenty-six localities were documented during this timeframe and reproduction was observed at only five of these localities (Ross et al. 1995).

We report the results of surveys since 1995 by the Utah Division of Wildlife Resources (UDWR) to better determine the current distribution of *B. boreas* in Utah and determine the extent of occupancy in areas with detections. This effort has consisted primarily of daytime visual encounter surveys (Crump and Scott 1994) during the breeding season. Surveys were generally systematic as initial surveys were completed statewide at or near pre-1995 localities and expanded to suitable habitat near detection points to

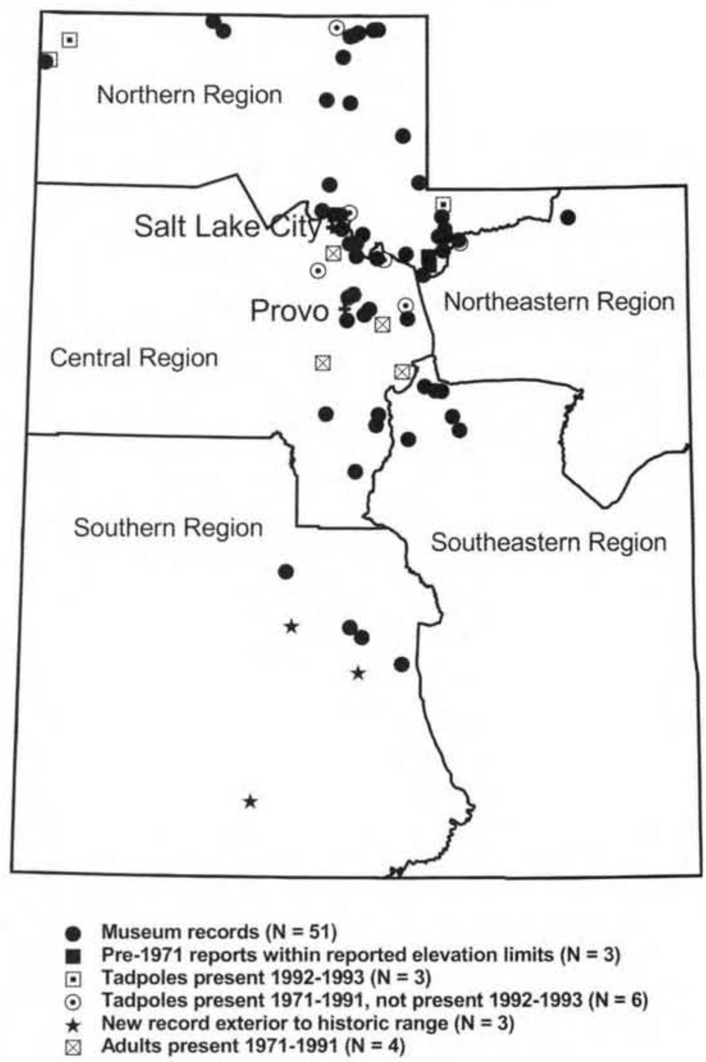

FIG. 1. Pre-1994 distribution of *Bufo boreas* in Utah (adapted from Ross et al. 1995).

delineate local populations. Fifty-eight of the 70 pre-1995 localities were revisited and surveyed. Survey effort varied because of the complexity of *B. boreas* habitat in Utah. In dry regions of the state, surveys were completed at springs as small as 10 m^2, while some surveys encompassed all habitats within portions of drainages (more than 0.5 km^2). Multiple visits were made in areas with detections, while areas where *B. boreas* were not observed generally were not revisited. No detections are not reported as one survey is not adequate to determine occupancy due to the temporal variability in amphibian populations.

Springs, streams, ponds, small lakes, and reservoirs were targeted for surveys. Effort was concentrated in springs, beaver (*Castor canadensis*) dam complexes, areas of shallow (less than 30 cm) open water with emergent and submerged vegetation, wet meadows adjacent to wetland habitat, and small mammal burrows upland from wetland sites. Surveys were conducted by searching the perimeter of all streams, ponds, and lakes, and conducting parallel transects to achieve 100% coverage of wet meadows and shallow ponds and marshes (Fridell et al. 2000). Some locality information, however, was collected from detection of single individuals in non-breeding habitat. Date, locality, observer, county, Universe Transverse Mercator (UTM) coordinates, and the number of each life stage (juvenile/adult, metamorph, tadpole, and egg strand) were recorded for all detection points. *Bufo boreas* captured during surveys were examined for clinical signs (e.g., loss of righting reflex, leg extension, failure to flee, skin tags, and subcutaneous hemorrhages) of infection of chytrid fungus (*Batrachochytrium dendrobatidis*).

Between 1995 and 2003, *B. boreas* were observed at 102 localities (Fig. 2) in more than 1100 discrete surveys. *Bufo boreas* were found at 84 previously undocumented localities and were present at 18 of 58 pre-1995 localities. Sites with *B. boreas* were clustered in 12 geographically distinct areas, likely representing discrete populations (Fig. 2). The majority of the *B. boreas* populations were found in two of the five UDWR management regions (Fig. 2).

Breeding (presence of egg strands and/or tadpoles) was observed in 54 locations within nine of 12 geographic areas (Fig. 2). Limited distributional information has been gathered on the three geographic areas (Strawberry Reservoir, Cottonwood Canyons, and North Horn Mountain) where *B. boreas* breeding has not been documented. In Cottonwood Canyons and North Horn Mountain, few adult *B. boreas* have been encountered, while 30 adults were encountered during 2003 surveys in the Strawberry Reservoir geographic area. Areas used by *B. boreas* for breeding are highly variable from year to year with spatial shifts corresponding to changes in habitat quality, water level, and vegetation. Since 1995, *B. boreas* breeding habitat has disappeared at one isolated breeding pond in northern Utah due to drying associated with drought. Additional breeding localities seemed to have shifted to more suitable habitat, when breeding habitats changed.

Consistent with Ross et al. (1995), we found *B. boreas* to primarily occupy montane habitats. In northwestern Utah, *B. boreas* were found primarily in lower elevation springs, which had been dredged and bermed to create small ponds for livestock watering; no fish were present in these habitats. The upland vegetation community varied from pinion-juniper/sage brush to aspen/mountain fir/mountain shrub. In higher elevations, *B. boreas* were found in wetlands and streams. *Bufo boreas* were found in eight streams containing native Bonneville cutthroat trout (*Oncorhynchus clarki utah*) and one stream containing brook trout (*Salvelinus fontinalis*). The upland vegetation community consisted of aspen/lodgepole pine. *Bufo boreas* were observed in northern Utah at elevations ranging from 1570 to 2800 m. In southern Utah, most *B. boreas* were found in wetlands associated with flowing streams, particularly in areas with recent *C. canadensis* activity (4 of 4 geographic areas). *Bufo boreas* were found in one stream containing brown trout (*Salmo trutta*), four streams with rainbow trout (*Oncorhynchus mykiss*), two streams with *S. fontinalis*, and four streams with *O. c. utah*. *Bufo boreas* were occasionally observed in off-channel wetlands, lakes, and ponds. The upland vegetation community varied from spruce fir/aspen to mountain fir/ponderosa pine. Populations were located at slightly higher elevations in southern Utah, ranging from 2390 to 3220 m.

FIG. 2. Distribution of *Bufo boreas* in Utah based on observations between 1995 and 2003.

Chytrid fungus was detected in one of 12 geographic areas during the survey effort. The diagnosis was confirmed when two *B. boreas* from the Paunsagunt Plateau tested positive according to the National Wildlife Health Center in August 2001. No other populations have been tested for chytrid fungus, however, no clinical symptoms have been observed to date.

Surveys between 1995 and 2003 have better defined the current distribution of *B. boreas* in Utah (Fig. 1). Ross et al. (1995) reported that very few recent localities, specifically breeding localities, were known to exist in Utah. Between 1995 and 2003, the UDWR documented the presence of *B. boreas* at 102 localities and 54 breeding areas within 12 geographically isolated populations (Fig. 2). *Bufo boreas* are widely distributed in Utah with populations persisting in northern and southern Utah (Fig. 2). Even though *B. boreas* were not detected in more than 1000 discrete surveys, temporal variability in amphibian populations coupled with the variability in survey effort among habitats does not indicate absence. Few *B. boreas* were found in the Wasatch Mountains between Salt Lake City and Provo, which could be attributed to the expanding human population along the Wasatch Front. Survey efforts in this part of the state, however, have not been as intensive. More surveys are needed to determine the distribution, population status, and factors influencing *B. boreas* distribution in these mountains. Future surveys may document *B. boreas* in additional geographic areas in Utah.

Acknowledgments.—For their field efforts, we thank Kristen M. Comella, Robert J. Curtis, K. Erika Dutcher, Gregg N. Garnett, Matthew S. Gowans, Deborah L. Harstad, Stephen E. Jones, Ben K. Nadolski, Jeremy L. Nikolai, Martin A. Schijf, Tammy K. Smith, James S. VanLeeuwen, Melanie A. Webb, and Brian A. Zettle. We are very grateful to Steve Brazier, Paul Chase, Paul Cowley, Ron Rodriquez, Krissy Wilson, Kevin Christopherson, Craig Walker, and Jim Whelan for coordination, technical, and logistic support. Special thanks to David E. Green of the National Wildlife Health Center for completing pathology tests on boreal toad samples. We also thank Don McIvor, the United States Forest Service, and the Bureau of Land Management for providing new and recent *B. boreas* locality information. The Utah Division of Wildlife Resources funded this project.

Captive Breeding of *Notophthalmus viridescens* Through Hormonal Manipulation

CRAIG CAMERON

Model organisms such as *Notophthalmus viridescens*, which possess regenerative ability, can offer great insight into the mechanisms of regeneration. Improved techniques for increasing the availability of embryos under laboratory conditions will allow comparative studies between development and regeneration and enable the manipulation of embryos to determine which genes are necessary for regenerative ability.

The effect of the environment, including temperature and photoperiod, on amphibian reproduction has been well documented. Photoperiod has proven to significantly affect spermatogenic cycles and ovarian development. It has also been shown that inappropriate temperatures can decrease gametogenesis (Duellman and Trueb 1986). Under laboratory conditions, inadequacies in environmental, social or nutritional cues necessitate the use of hormonal manipulation for the successful generation of large numbers of embryos (Whitaker 2001). A variety of hormones have been used in amphibian reproduction. These include Human Chorionic Gonadotropin (HCG), Luteinizing Hormone-Releasing Hormone (LH-RH), Follicle Stimulating Hormone (FSH), and Gonadotropin-Releasing Hormone (Gn-RH) (Whitaker 2001). Most of these studies have been done with anurans and there is very little information on urodeles.

Khan and Liversage (1995) developed a technique for spawning and rearing *Notophthalmus viridescens* embryos under laboratory conditions. Their method uses a combination of manipulation of photoperiod, temperature and hormones. Our current communication improves and simplifies the method for obtaining embryos by eliminating the need for manipulation of temperature and photoperiod or the selection of pre-conditioned animals.

Adult maintenance.—Adults in our colony are maintained under standard conditions (Foty and Liversage 1993) with some modifications. A bed of oak leaves (sterilized by autoclaving) is layered on the bottom of the tubs. The oak leaves provide shelter for the newts, and anecdotal evidence suggests that degradation products such as fulvic acid provide anti-bacterial and anti-microbial properties and help in the absorption of nutrients and minerals (www.fulvic.com). Pine or cedar products should not be used, as the compounds they release are harmful to many amphibian species (Barnett et al. 2001). Newts are fed twice weekly with live blackworms (*Lumbriculus variegates*), which are high in protein and live in the enclosure until they are eaten. The use of live prey decreases the amount of husbandry time by eliminating the need

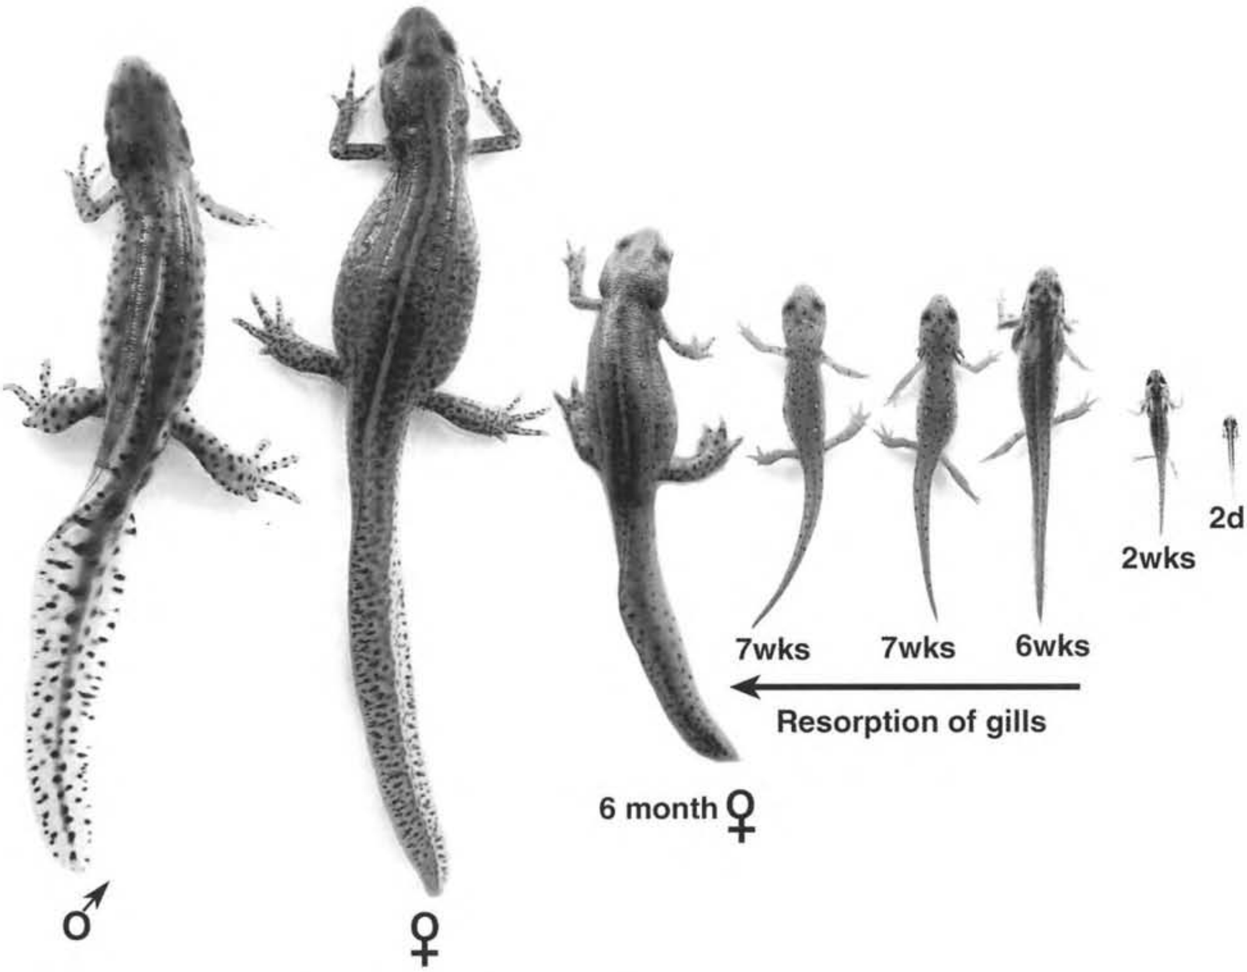

FIG. 1. Time (post-hatching) of development in our captive-bred population.

to clean out decaying uneaten food.

Hormonal manipulation.—Adult *Notophthalmus* chosen for spawning are moved to alternate containers for ease of identifying injected individuals and for ease of embryo collection. Plastic containers with adequate height to accommodate a minimum water depth of 15 cm are suitable. Aquatic plants (e.g., *Elodea* sp.) or plastic plants fixed by silicone rubber to large stones are placed on the bottom of the enclosure as egg laying locales.

The injection procedure is as follows:

1. Male and female animals are mildly anesthetized by submersion for 5–10 minutes in 0.05% MS-222 (buffered to pH 7.0 with $NaHCO_3$).
2. An intraperitoneal (IP) injection of 30 international units (IU) of prolactin (PRL – Sigma, Cat. # L6520) is administered.
3. Animals are re-treated after 72 h and again after another 72 h for a total of three injections.
4. Forty-eight hours after the last PRL injection, females are re-anesthetized and injected IP with 100 IU of human chorionic gonadotropin (HCG – Sigma, #CG-5; see Khan and Liversage 1995). We have found that males do not require an HCG injection for successful captive breeding using our method.
5. A second injection of HCG is administered to the females after 24 h.

Typically, eggs begin to appear within 72 h after the last HCG injection, and females will continue depositing eggs for several weeks, usually resulting in 150–200 viable embryos per female. Eggs are generally attached to submerged aquatic plants. Priming with PRL eliminates the need for using animals that already display secondary sexual characteristics such as nuptial pads on the hindlimbs in males and the prominent distension of the cloacal region in females. In several urodele species, PRL has been shown to induce migration to water, and to promote courtship behavior and development of secondary sexual characteristics (Iwata et al. 2000). We have found that the use of PRL injections prior to HCG has also improved the viability of our embryos. PRL is pivotal in the female's production and secretion of oviducal jelly (Duellman and Trueb 1986), and HCG alone might not produce this jelly effectively. The oviducal jelly secretions, which ultimately become the mucoid capsules, encase the embryo and are responsible for prevention of fungal infections and other defensive strategies (Duellman and Trueb 1986).

Embryos and larvae.—Once eggs are deposited, they can be removed delicately from the plants with the use of tweezers and a disposable transfer pipette. Eggs should be removed daily, if possible, to prevent them from being eaten by the adults. Eggs are then housed in petri dishes, and non-viable embryos are removed immediately so that degradation and the subsequent fungal growth that may ensue does not contaminate the remaining embryos. The eggs should always be totally submerged in water and the lid should be kept on the petri dish to prevent water evaporation and desicca-

tion of embryos. Once the eggs have hatched the tiny larvae can be placed in plastic containers with aerated water. Submerged oak leaves in the larval enclosures provide shelter but also promote growth of algae from the nutrients leached by the slowly decaying leaves. Cultures of *Daphnia* sp., *Cyclops* sp., and other minute aquatic organisms (Aquatic Foods, Inc. or Carolina Biological Supply Co.) are introduced into the enclosures. These organisms will feed on the algae and will in turn provide food for the larvae. Once the larvae are about 1.5 cm long, they can be fed on blackworms like the adults. Powerful filters should not be used in the enclosures as the larvae will be drawn into the filter. Aeration with weekly partial water changes should be adequate in most cases. Approximately 30 larvae can be housed in a container 40 cm x 27 cm x 15 cm. Overcrowding the larvae will increase the likelihood of cannibalism and increase the amount of waste build-up between cleanings.

Efts.—Typically, *Notophthalmus viridescens* goes through a terrestrial eft stage which lasts from 3 to 7 years (Healy 1974). In captivity the terrestrial stage can be bypassed by keeping the newts in a shallow aquatic environment with the same set up used for the adults but with a water depth of only 5 cm and either rocks or plastic plants to break the water surface. This allows the newts to adjust more easily to the aquatic environment. Young newts are fed predominantly on blackworms like the adults. Although faster growing rates than 3–7 years have been observed with aquatic juveniles under natural conditions (Healy 1974), we have been able to attain sexual maturity in our offspring in as few as six months by using the conditions outlined above (see Fig. 1 for developmental staging). Although these animals are smaller in stature than the full-grown adults, we have obtained viable embryos from their matings. In nature, the development of terrestrial efts is restricted by availability of food, rainfall, and the number of suitable days for hunting (Healy 1974). Our juveniles are fed three times a week on blackworms, which provide sufficient caloric intake to accelerate maturation rates.

Acknowledgments.—This work was financially supported by the Natural Sciences and Engineering Research Council of Canada, and by the Canadian Institutes of Health Research.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 35, Number 1 (March 2004).

ANURA

BUFO GRANULOSUS (NCN). **PREDATION**. On 24 Oct 2002 at Lagoa Grande, 30 km from the municipality of Pontalina (17°31'23"S, 49°26'49"W; 642 m elev.), in the southern portion of the State of Goiás, central Brazil, we observed an individual *Leptodactylus podicipinus* (33.9 mm SVL) predating an individual *Bufo granulosus* (19.8 mm SVL) at 2050 h. This interaction was observed in a soil cavity ca. 5 cm deep in a humid pasture. Although the right rear leg and part of the abdomen of *B. granulosus* had already been swallowed by *L. podicipinus*, it continued to struggle. These specimens were collected, and immediately after capture, *L. podicipinus* released the *B. granulosus*, which died within a few minutes. These specimens are deposited in the collection of the Laboratory of Animal Behavior of the University Federal of the State of Goiás, Goiânia (ZUFG 1846 *B. granulosus*; ZUFG 1847 *L. pocidipinus*). This observation suggests that *L. pocidipinus* is a predator of *B. granulosus*, and that the skin toxins of *B. granulosus* might not be an effective defense against *L. podicipinus*.

Submitted by **LORENA DALL´ARA GUIMARÃES**, **RICARCO MARQUES PINTO**, and **RAFAEL DE FREITAS JULIANO**, Depto. de Biologia Geral - ICB – UFG, Campus II, Caixa Postal 131, 74001-970, Goiânia, Goiás, Brazil; e-mail (LDG): dallaraelm@uol.com.br.

LEIOPELMA HAMILTONI (NCN). **HOMING**. Translocations of frog species are likely to become more prevalent in future years as researchers and conservationists attempt to be more proactive in halting the global demise of many frog species (Waldman and Tocher 1998. Behavioral Ecology, Genetic Diversity, and Declining Amphibian Populations. *In* T. Caro (ed.), Behavioural Ecology and Conservation Biology. Oxford University Press, Oxford.). It is possible that animals attempting to return home will hinder translocation efforts for some species. For rare or threatened amphibian species, the loss to the total population of individuals that unsuccessfully home may significantly jeopardize the long-term persistence of the species. Animals that attempt to home also compromise successful establishment of the translocated population.

The primitive leiopelmatid frogs of New Zealand comprise four extant species, two of which (*Leiopelma pakeka* and *L. hamiltoni*) are now restricted to offshore predator-free islands in the Marlborough Sounds. *Leiopelma hamiltoni* is present only on Stephens Island and has an estimated population size of 169–318 individuals (Brown 1994. New Zealand J. Zool. 21:425–430; Thomson 1996. B.Sc. [Hons.] Thesis, Victoria University of Wellington, Wellington), all living in a rock tumble ca. 300 m^2. *Leiopelma hamiltoni* is the most threatened of New Zealand's endemic frogs.

All New Zealand *Leiopelma* spp. are subject to a formal Recov-

ery Plan (Newman 1996. Native Frog (*Leiopelma* spp.) Recovery Plan. Threatened Species Recovery Plan No. 18, Dept. Conservation, Threatened Species Unit, Wellington, New Zealand), which is administered by a Recovery Group, under the auspices of the Department of Conservation. The Recovery Plan proposed the establishment of two additional populations of *L. hamiltoni*: a second population on Stephens Island, and another on a different, predator-free island in the Marlborough Sounds.

On Stephens Island, clearing, browsing, and subsequent wind-damage to the remaining forest early this century destroyed much of the forest cover. *Leiopelma hamiltoni* were likely to have been more widely distributed on Stephens Island and have become restricted to the rock tumble since the forest was cleared (Brown 1994. *op. cit.*). Tuataras are present in high numbers on Stephens Island, and may have benefited from the clearing of the forest and subsequent patchy regeneration of vegetation. It is likely that tuatara play a significant role in restricting *L. hamiltoni* to the rock tumble (Newman 1977. Proc. New Zealand Ecol. Soc. 24:43–47; Brown 1994, *op. cit.*).

In 1991 a new habitat was built for *L. hamiltoni* on Stephens Island (Cree 1990. Habitat restoration for Hamilton's frog. Unpubl. Rept., Dept. Conservation, Wellington, New Zealand; Brown 1994. *op. cit.*). A rock pit ("frog pit") was built ca. 70 m from the existing frog habitat in an exposed rock tumble ("frog bank"), and was fenced to exclude tuatara. The frog pit was located within a forest remnant. Twelve frogs were transferred to the pit in May 1992. Of these transferees, five were presumed to be adult females, and seven were adult or subadult males or subadult females (Bell 1978. Herpetologica 34:340–354; Brown 1994. *op. cit.*). Frogs were toe-clipped prior to their release into the frog pit.

During the year following the translocation, 50 searches yielded 27 recaptures of 7 of the 12 translocated frogs (Brown 1994. *op. cit.*). As the years have passed, fewer of these frogs have been recaptured, and now only 3 of the translocated frogs are known to remain at the frog pit (Tocher and Brown *unpubl. data*).

Newman (1990. Herpetologica 46:319–330) found that *L. hamiltoni* could home accurately over 10 m, and homing was seen as a potential confounding problem in the translocation of *L. hamiltoni* (Brown 1994, *op. cit.*). The apparent success of the *L. pakeka* translocation on Maud Island (Bell 1994. New Zealand J. Zool. 21:341–349) provided evidence that new populations could be established, and the Recovery Group decided the "risk" of perhaps losing a number of *L. hamiltoni* through homing was worth taking to potentially establish a second population. Herein we provide data on two homing events (from the frog pit back to the frog bank).

Stephens Island is located at one of the northern-most points of South Island, New Zealand and is exposed to Cook Strait. In 1989 planting of wind-tolerant species such as ngaio (*Myoporum laetum*), taupata (*Coprosma repens*), and akiraho (*Olearia paniculata*) was begun between the frog bank and frog pit. Now, the frog bank is effectively linked to the original forest remnant and the frog pit by vigorous growth of plantings and the seedlings that are establishing beneath them.

Searches of the frog bank, and later the frog pit (from 1992) for toe-clipped animals were made intermittently between 1990 and 1996 (Thomson 1996, *op. cit.*). Since July 1997, searches have been conducted at least four times per year, and each search usually takes place over a period of six or more days. Up to June 2000, there have been 61 captures of 8 of the 12 translocated frogs. Four of the frogs have never been seen since release into the frog pit. Three others have not been seen since 1992, 1993, or 1994. Of the three adult frogs remaining in the frog pit, two are females and one is likely to be a male (based on SVL remaining constant at 39 mm over the last few years; Bell 1978, *op. cit.*; Brown 1994, *op. cit.*).

Two frogs have homed back to the frog bank and another may have attempted to home. A male *L. hamiltoni* (Frog B) was last seen in the frog pit in October 1994 and was recaptured on the frog bank in April 1995. The capture site for this frog in April 1995 was 0.2 m from the site where it was originally captured prior to translocation in May 1992. Since arriving back at the frog bank, the frog has been recaptured on two other occasions, both times in the vicinity of the original capture site. The distance between the last capture site in the frog pit and the site Frog B was captured in the frog bank is ca. 76 m.

Brown (1994, *op. cit.*) reported that two frogs (Frog B and C) seemed to be moving away from the release site in the frog pit, towards the frog bank, several months after the release (based on capture locations). Frog B did eventually home back to the frog bank, but Frog C has not been seen since February 1993.

The second frog to home was a female *L. hamiltoni* (Frog I) that was last seen in the frog pit in Feb 1993, nine months after the release, and was recaptured on the frog bank in June 1999. The capture site in June 1999 was 3.1 m from its original capture site in May 1992, and 89 m in a straight line from the site the frog was last seen at in the frog pit.

The translocation of *L. hamiltoni* has highlighted the need for a thorough consideration of life history and behavioral attributes of species prior to the initiation of translocations. A high mortality rate is expected in amphibians that attempt to home across modified or otherwise inhospitable habitats. The habitat between the frog pit and frog bank is relatively inhospitable to *L. hamiltoni*. The presence of tuatara and burrowing seabirds, sparse vegetation and the relative paucity of deep rock piles all combine to deter colonization of this habitat by *L. hamiltoni*. Over the period that the *L. hamiltoni* population on Stephens Island has been studied (from 1975) frogs have never been observed in the area between the frog pit and frog bank. Even in recent years as the forest between the two habitats has regenerated, no sightings have been recorded (although no thorough and systematic searches have been made).

It is unlikely that there are any adult frogs in the frog pit, other than the three known to be resident. These 3, plus the 2 frogs known to have returned to the frog bank, account for 42% of the translocated frogs, meaning that 58% are unaccounted for, eight years after the translocation. By way of comparison, 53% of frogs marked between 1990 and 1991 are "unaccounted for" in the frog bank, after a similar period of time.

Some of the "missing" frog pit frogs may still be in the process of homing back to the frog bank. The habitat surrounding the frog pit may be more suitable for *L. hamiltoni* than it seems, and some of the transferees may have taken up residence in the habitat between the frog bank and frog pit. Alternately, they could have succumbed to natural mortality, or unsuitable habitat (e.g., drying conditions), or been predated. It is also possible that they have re-

mained undetected at either the frog bank or frog pit (19% of frogs marked at the frog bank between 1990 and 1991 were not seen again for over nine years despite repeated searches).

Threatened frog species, such as *L. hamiltoni*, do not exist in high enough numbers to sustain regular cropping to establish other populations, and even a single cropping may be cause for concern. The likelihood of translocated frogs returning home may be minimized by translocating young animals that have not yet fully established a home range. Also, frogs may be more likely to home when they are not involved in breeding.

We advocate that for any future translocations, strong consideration be given to the transfer of subadult frogs. The three frogs that have remained in the frog pit had yet to attain full size when transferred, while the two that "homed" were at full size. Subadults may have fewer tendencies to attempt homing, and their removal from the founding population does not immediately compromise breeding and population recovery potential.

Submitted by **MANDY D. TOCHER**, Science and Research Unit, Science Technology and Information Services, Department of Conservation, P.O. Box 5244, Dunedin, New Zealand (e-mail: mtocher@doc.govt.nz), and **DEREK BROWN**, 4 Main Road, Havelock, New Zealand (e-mail: derek.brown@xtra.co.nz).

MELANOPHRYNISCUS MONTEVIDENSIS (Darwin's Toad). **ALBINO LARVAE**. Published reports of albino amphibians and reptiles have become more common in the last years. However, these records are mainly based on reptiles rather than amphibians. Albinism in amphibians in Uruguay has not been reported previously.

During a field trip to Cabo Polonio, Rocha Department, Uruguay (34°24'S, 53°47'W), several male *Melanophryniscus montevidensis* were observed calling in a temporary pond (1 m diam, 0.5 m max depth, stone bottom) on 13 Feb 2003, 24 h after an intense rainfall. On 20 Feb 2003, when the pond was nearly dry, several tadpoles were collected and placed in a glass container. We noted that twelve tadpoles were complete albinos, whereas the other individuals showed normal pigmentation. Nine albino larvae died before reaching Gosner stage 30 (Gosner 1960. Herpetologica 16:183–190), the others were fixed in formalin at Gosner stage 35. All normal tadpoles survived. Specimens were deposited in the Zoología Vertebrados Batracios Collection, Facultad de Ciencias, ZVCB 10505). On 24 Feb 2003, after another rainfall, three amplectant pairs of *M. montevidensis* were observed. They were collected and placed in a glass container. Twenty-four hours later, six small egg clutches (two clutches by each pair) were found in the container; the toads were released at the same place where they had been collected. After a week, no albino tadpoles were observed in the container.

Whereas other reports of albinism in tadpoles indicate that albinos had neither different mortality nor developmental rates (Nijs 2002. Herpetol. Rev. 33:131), we observed the normally colored tadpoles survived better than albinos. Differential features between albino and normal tadpoles were not observed in the tooth row formula or in the general body shape.

We thank Axel Kwet for helpful suggestions on the manuscript.

PROBREVICEPS LOVERIDGEI, P. ULUGURUENSIS, and ***P. MACRODACTYLUS*** (Loveridge's Forest Frog, Uluguru Forest Frog, Long-fingered Forest Frog). **ADVERTISEMENT CALLS**. The forest frogs are robust, short-limbed, burrowing microhylids that are found in some old mountain forests in Africa. Five species are known, of which four are found in the high Eastern Arc mountain forests of Tanzania, and one, *Probreviceps broadleyi*, is found in the mountains between Mozambique and Zimbabwe. Not one of the calls of these species has been described.

Probreviceps loveridgei is known only from the Uluguru Mountains in Tanzania, where it occurs between 1200 and 1500 m elevation. *Probreviceps uluguruensis* is also confined to the Uluguru Mountains, where it occurs at altitudes of 2000 m and above. *Probreviceps macrodactylus* is known only from the Usambara Mountains of northern Tanzania. We report the advertisement calls of the above three species (Fig. 1). Recordings were made in the field, using a Sony TC-D5M cassette recorder, or a Sony Microcassette Corder M-730V. The calls were analyzed using CANARY 1.2.4 (Cornell Laboratory of Ornithology). Voucher specimens are in the collection of the Zoology and Marine Biology Department, University of Dar es Salaam.

Probreviceps loveridgei was recorded on 22 Aug 2002 by FJM at Shikurufumi Catchment Forest (Southern Uluguru Mountains) at an altitude of 1500 m. Air temperature was 14°C. Males call from burrows or leaf litter after rain. Calls from a single typical male consist of 3–6 notes at an emphasized frequency of 1.67 kHz. The mean call duration is 457 ms (range 332–697, N = 10). Each note consists of 1–5 pulses with a pulse rate of 43–91/sec.

Probreviceps uluguruensis was recorded on 1 Sept 2002, Uluguru South Forest Reserve at an altitude of 2000 m by FJM, and 30 Nov 2002 on the Lukwangule Plateau, Uluguru Mountains at an altitude of 2450 m by WN. Air temperature was 9.7°C and 12°C. Males call from grass tussocks along wetlands or under leaf litter in forest. The call is a low-pitched chirp. Typical calls from two males, one at an altitude of 2000 m in the Uluguru South

FIG. 1. Typical calls of *Probreviceps loveridgei* (L), *Probreviceps macrodactylus* (M), and *Probreviceps uluguruensis* (U).

Forest Reserve, and the other at 2440 m on the Lukwangule plateau, consist of 6–8 notes at a frequency of 1.41kHz, and 3–6 notes at a frequency of 1.37 kHz. The mean call duration for both samples is 269.3 ms (range 107–349, N = 11). The mean note rate is 20.4 notes/sec (range 18.6–22.0).

Probreviceps macrodactylus was recorded at Amani in the East Usambaras, on 13 March 2000. Air temperature was 22°C. Males call from burrows or concealed beneath vegetation after rain. The call is a low-pitched chirp. The calls of a single typical male consist of 12–13 notes at a dominant frequency of 1.87 kHz. The mean call duration is 308 ms (N = 4). The mean note rate is 38 /sec (range 37.8–38.2).

We thank the local authorities for permission to work in these areas. AC acknowledges a research permit issued by COSTECH.

RANA BLAIRI **(Plains Leopard Frog). PREY.** Although there are accounts of the distribution, habitat, and zoogeography of *Rana blairi*, specific studies that refer to their feeding habits are scarce (Collins 1993. Amphibians and Reptiles in Kansas. 3rd ed., rev. Univ. Kansas Nat. Hist. Mus. 397 pp.; Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed. Indiana Acad. Sci., Indianapolis. 404 pp.). During the spring of 2001 and 2002, we collected *R. blairi* for studies on parasite ecology (Bolek et al. 2003 J. Parasitol. 89:522–528) and to document examples of predation on the Western Chorus Frog, *Pseudacris triseriata*. During the nights of 30–31 March and 2 April 2001 individual male *R. blairi* were observed among choruses of *P. triseriata* in an overflow temporary pond located on the North East side of Pawnee Lake, Lancaster County Nebraska (40°51.18'N, 96°53.11'W). None of these male *R. blairi* at this or two other locations around Pawnee Lake was heard calling on these dates, although we spent 2–4 h/night at this location. Observations on these male *R. blairi* indicated that they were fully submerged with only the eyes and nostrils exposed above the water and facing calling male chorus frogs. It appeared as if the male *R. blairi* were homing in on the calls of the male *P. triseriata*. Although no predation attempts were observed in the field, all 3 male *R. blairi* collected from this site on 30-31 March and 2 April 2001 and 3 of 10 male *R. blairi* collected from an overflow temporary pond on the western side of Pawnee Lake on 14 April 2002 contained undigested frogs or bones of *P. triseriata* in their stomachs. Additionally, a single female Bullfrog, *R. catesbeiana,* collected at this location on 10 April 2001 contained a *P. triseriata* in its stomach. Recently McCallum et al. (2003. Herpetol. Rev. 34:54) observed a similar phonotactic stalking behavior in Wood Frogs, *R. sylvatica*, preying on Spring Peepers, *P. crucifer*, in Arkansas. Our observations suggest that numerous *Rana* species that overlap during their breeding season or location with *Pseudacris* sp. may commonly prey on these frogs, suggesting that calling by male *Pseudacris* sp. may be costly. Our observations suggest another hypothesis for the presence of non-calling or "satellite " males in close proximity to calling conspecific males of *P. triseriata* and other *Pseudacris* sp. (Robel 1985. J. Herpetol. 19:432–436; McCallum et al. 2003. Herpetol. Rev. 34:53).

We thank Melissa Ewert for help in collecting frogs, and the Nebraska Games and Parks Commission for scientific collecting sub-permit to MGB (Sub-Permit No. 226). This work was supported by grants from the Initiative for Ecological and Evolutionary Analysis, University of Nebraska—Lincoln, The Franklin Kestner Memorial Fund School of Biological Sciences University of Nebraska—Lincoln, and the Center for Great Plains Studies graduate student Grant-in-aid University of Nebraska—Lincoln.

***RANA* SPP.** (Multiple Ranid Species). **HIBERNACULA.** Overwintering locales for adult Green Frog (*Rana clamitans*), Pickerel Frog (*R. palustris*), and American Bullfrog (*R. catesbeiana*) have been documented, though these species are primarily known to hibernate either singly or with conspecifics. We present here what we believe to be the first account of a shared hibernaculum of multiple species of ranid frogs of different age classes.

On 12 March 2003, we observed 16 individuals representing three species of ranid frogs under a sandstone rock (73 x 75 x 12 cm) at the edge of a small (15.4 x 7.3 m) pond on US Department of Agriculture property in Beltsville, Maryland (39°02'00.9"N, 76°51'27.9"W). The rock was partially submerged at the northwestern edge of the pond basin, at a maximum depth of ca. 18 cm. Air temperature was 13.7°C, and water temperature at the edge of the pond basin was 11.5°C. Water temperature under the rock where we found the ranid frogs was 5.2°C. The species, age class, sex (if it could be determined), and SVL were as follows: 3 *R. palustris* adult males (40, 45, 52 mm SVL), 6 *R. clamitans* juveniles (mean 36 mm SVL, range 28–46 mm), and 7 *R. catesbeiana* juveniles (mean 34 mm SVL, range 30–40 mm).

Individuals retrieved from under the rock were extremely sluggish, and we presumed that they were hibernating. In addition, a single adult *R. catesbeiana* was discovered under an artificial plywood cover board (61 x 122 cm) adjacent to the pond, suggesting that the individuals discovered under the rock were not simply seeking cover, as there were many other cover boards located near the pond's edge which were unoccupied.

Comparisons of photographs from this site taken in 2001 and 2002 indicate that the water level was higher in 2003 than in the previous two years, and that this hibernaculum was not adjacent to the water or inundated in the previous two years.

Although the hydroperiod of this pool was not observed during the winter months, the large amount of precipitation and snowmelt in late 2002 and early 2003 suggests that the water level was high enough to reach and inundate the hibernaculum during the hibernation period. These ranid frogs typically move to hibernation sites in October and November in Missouri and Pennsylvania (Willis et al. 1956. Copeia 1956:30–41; Hulse et al. 2001. Am-

phibians and Reptiles of Pennsylvania. Cornell University Press, Ithaca, New York, 419 pp.).

This hibernaculum was discovered while conducting work associated with the U.S. Geological Survey's Amphibian Research and Monitoring Initiative, Northeast Region.

SCAPHIOPUS COUCHII (Couch's Spadefoot). **PREDATION.** *Scaphiopus couchii* is an explosive, opportunistic breeder that congregates around ephemeral pools following heavy rains. After a short larval period, tadpoles emerge in high densities over short periods (Stebbins and Cohen 1995. A Natural History of Amphibians. Princeton University Press, New Jersey, p. 86). *Masticophis flagellum* is an active foraging, diurnal predator whose diet includes small mammals, birds and their eggs, snakes, lizards, small turtles, frogs, and occasionally grasshoppers (Reams and Aucone 2001. Herpetol. Rev. 32:108; Werler and Dixon 2000. Texas Snakes. Texas A&M Univ. Press, Texas, p.182; Tabor and Germano 1997. Herpetol. Rev. 28:90; Ward and Clark 1988. Herpetol. Rev. 19:36–37; Tyler 1986. Oklahoma Ornithol. Soc. Bull.19:14–15). On 19 July 2002, we found an adult *M. flagellum* (162 cm TL; 141 cm SVL) foraging ca. 1 m from the edge of an ephemeral pool in Big Bend National Park, Brewster County, Texas (Zone 13R 3239700N, 646820E) where hundreds of *S. couchii* metamorphs were emerging. Although no predation events were observed, palpation yielded four *S. couchii* metamorphs with tails (mean 14.3 mm SVL). Opportunistic foraging upon recently metamorphosed toadlets can undoubtedly provide a tremendous amount of energy for a given snake. While, to the best of our knowledge, predation upon *S. couchii* by *M. flagellum* has not been documented, it is likely that these snakes utilize this food source on a regular basis during the summer months when numbers of metamorphosing amphibians are often greater than 10,000 individuals per night (Gray 2002. Effects of Anthropogenic Disturbance on Body Size, Demographics, and Chaotic Dynamics of Southern High Plains Amphibians. Ph.D. Thesis, Texas Tech University).

TESTUDINES

ACANTHOCHELYS MACROCEPHALA (Pantanal Swamp Turtle). **HABITAT**. *Acanthochelys macrocephala* is a poorly known South American chelid turtle with a geographical distribution restricted to the Paraguay River basin in western parts of central Brazil, Paraguay, and possibly Bolivia (Rhodin et al. 1984, Herpetologica 40:38–46). This range encompasses mainly flooded lands and cerrados (savanna-like vegetation) known as Chaco and Pantanal, and at a local scale this habitat is quite diverse. Marshes, slow-flowing streams, and pastures are defined as *A. macrocephala* habitat in Brazil (Rhodin et al. 1984, *op. cit.*; Cintra and Yamashita 1989. Herpetol. Rev. 20:65–66). During intensive field work conducted in Mato Grosso do Sul State in recent years it was possible to collect turtle skeletal remains and to capture and observe living turtles. Collections were made in two areas of Nhecolândia Pantanal (18°57'S, 56°37'W and 19°34'S, 56°14'W). The region is characterized by the presence of hundreds of ponds, regionally known as "baías" (shallow bays) and brackish ponds called "salinas" (salt lagoons), in lowland areas within a matrix of distinct cerrado physiognomies on higher ground (± 2 m). Turtle shell remains are frequently found associated with intermittent streams ca. 3 km from the salinas. During the rainy season the bays (excepting the salt lagoons) connect through small intermittent streams creating a shallow waterway that is utilized by migrating *A. macrocephala*. Individuals that fail to reach a waterway can die while traversing the dry cerrado uplands.

Baías and salinas are distinct. While bays can harbor several species of vertebrates (i.e., caiman, fish, frog) and plants (water lily, cattail), vertebrates are poorly represented in salinas, although occasionally caimans and a frog species (*Pseudis paradoxa*) can be found in these water bodies. In the salt lagoons, alkaline conditions (pH 10–12) promote diatomaceous algae and a rich invertebrate community, including crabs, dragonflies, and other aquatic insects. The ponds can be permanent or temporary. Soil composition, such as the relative amounts of silt or sand, influences the presence of aquatic plants in the lagoon and herbaceous plants at the edges. A grass, *Axonopus purpusii* (Poaceae), dominates the edges of the lagoons.

During the dry season (July–September), salinas can become partially or totally dry. In this period, distinct physiognomies from salt lagoon beach to the closest vegetation can be detected. A variably wide strip of beach in salt lagoons is destitute of vegetation. Instead, only decomposed algal remains are visible. Turtle bones are very common around these beaches. From this vegetation-free beach to the upland cerrado edge, a succession of grasses, shrubs, and trees is well distinguished. A predominant strip of *Digitaria* (Poaceae) grass with few herbaceous species is the first vegetation band. Next appears a tall grass, *Paspalum vaginatum* (Poaceae), together with *Digitaria* and few *Scirpus* (Cyperaceae). Reaching the upland, the vegetation around the salt lagoons is dominated by cerrado and semi-deciduous forests. Bordering the forest edge there are patches of dense bromeliads (*Bromelia balansae*).

The habitat of *A. macrocephala* in Brazil is subject to a pronounced wet-dry season rhythm. Interesting behavioral responses to such environmental stochasticity might be expected in these populations.

CHELYDRA SERPENTINA (Common Snapping Turtle). **REPRODUCTION.** On the morning of 7 June 2001, we observed a 2.9 kg female *Chelydra serpentina* digging a nest at the edge of a gravel road in Utica Marsh, an urban wetland next to the Mohawk River and lying partially within the city limits of Utica, New York, USA. The nest site was 53 m from the water on a direct line and within a ca. 30 x 60 m cleared area with a gravel road running along one margin. On closer inspection of the nesting activity, we found several damaged *C. serpentina* eggs from a prior nest in the soil being dug up by the female. As she continued digging, additional eggs surfaced. Palpation of the pelvic region of the laying female indicated that she had a full load of shelled eggs ready for oviposition. We left the animal undisturbed for an hour, and upon return, found the female covering the nest. We found numerous additional broken eggs around the nest site. Palpation indicated that no eggs remained in her body cavity. Twenty-three eggs were recovered from this nest and collected for hatching in the lab. Three undamaged eggs were salvaged from the previous nest of an estimated 15–20 eggs total.

To our knowledge, this represents a rare instance of *C. serpentina* using a previously excavated nest for her own, thus destroying the eggs of the first female. Anecdotal evidence provided by others suggests that this phenomenon has been observed in several species, including *C. serpentina, Glyptemys insculpta*, and seaturtles. One published study of nesting in *Malaclemys terrapin* reported that females would occasionally dig up other nests in high density nesting areas, but such incidents represented less than 2% of total nesting events (Burger 1977. Am. Midl. Nat. 97:444–464). We have been unable to find published reports of this type of nest destruction by *C. serpentina*, and such activity was not documented by Congdon et al. (1987. Herpetologica 43:39–54) in their thorough study of nesting ecology of *C. serpentina*.

Although predation of *C. serpentina* nests by other species is well established, it remains puzzling as to what mechanism other than chance led to this observed nest destruction by *C. serpentina* in a low-density nesting area containing only six nest sites within this 1800 m^2 nesting area. Difference in soil structure does not seem to be a factor nor does relative openness of each nest site in the area. One could speculate whether olfactory cues may have contributed to selecting the first nest as the site to excavate.

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **MIGRATION AND DISPERSAL.** While relatively large numbers of *Dermochelys coriacea* forage seasonally in temperate waters off Atlantic Canada (Bleakney 1965. Can. Field Nat. 79:120–128; Goff and Lien 1988. Can. Field Nat. 102:1–5; James and Herman 2001. Chelon. Cons. Biol. 4:202–205), the nesting origins of these animals are generally unknown. Until now, the only direct evidence of the nesting origins of leatherbacks found off eastern Canada came from a single animal bearing a flipper tag applied in French Guiana that was in Placentia Bay, Newfoundland, on 17 September 1987 (Goff et al. 1994. Can. Field Nat. 108:72–73). Here we report on the discovery of two previously marked female *D. coriacea* captured while conducting field research off the coast of Cape Breton Island, Nova Scotia, in the summer of 2002.

The first turtle, measuring 162 cm curved carapace length (CCL), was captured at 1500 h on 30 August 2002 at 46°49.891'N, 60°03.139'W. During examination, an Avid IV Multi-tag reader detected a Passive Integrated Transponder (Trovan #00-061D-4876) implanted in the turtle's right shoulder muscle. A small amount of scar tissue on the epidermis (approximately 2 cm^2) corresponded to the area above the implantation site. It was later established that the turtle had been tagged on 6 July 2001 at Kolukumbo Beach, at the eastern end of the Galibi Nature Reserve in Suriname (approx. 05°51.384'N, 54°07.813'W).

The second turtle (157 cm CCL) was captured at 0930 h on 7 September 2002 at 46°47.290'N, 60°11.180'W. Monel flipper tags (V1260, V1261) were discovered on the margins of both rear flippers. It was later confirmed that the turtle had been tagged on 12 May 2000 at Gandoca Beach (9°34.991'N, 82°35.091'W), on the southern end of the Caribbean coast of Costa Rica. At that time, the animal measured 156 cm CCL. She was observed nesting a second time at the same beach on 20 May 2000.

Although *D. coriacea* demonstrates a high degree of fidelity for island nesting sites, mainland nesters frequently nest across broad areas of coastline. This is true of the assemblage of *D. coriacea* in French Guiana and Suriname—now considered the world's largest nesting colony—where there is regular shifting of nesting activity between these countries in alternate nesting seasons and even in the same nesting season (Spotila et al. 1996. Chel. Cons. Biol. 2:209–222). The tag recovery from Suriname and the earlier flipper tag recovery from French Guiana, therefore, likely represent a common nesting origin. In fact, these two animals were tagged at sites that are less than 50 km apart.

The discovery of the turtle tagged in Costa Rica provides the first evidence of representation of an insular Caribbean nesting colony in the Canadian foraging population of *D. coriacea*.

I thank H. Fricker, B. Fricker, K. Martin, M. Rideout, M.Godfrey, Biotopic Foundation, Foundation for Nature Conservation Suriname, World Wildlife Fund Guianas, Archie Carr Center for Sea Turtle Research, Caribbean Conservation Corporation and Asociación ANAI. This work was supported by the Department of Fisheries and Oceans, the Nova Scotia Leatherback Turtle Working Group, World Wildlife Fund Canada, Environment Canada, and the National Marine Fisheries Service (USA).

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **PENIS DISPLAY.** *Dermochelys coriacea* males spend their entire lives at sea, where they are rarely encountered by researchers. Basic morphometric data on males is thus very limited, as it is typically only available from stranded turtles. Collaboration with commercial fishers has enabled us to examine and tag male and female *D. coriacea* in temperate waters off Nova Scotia, Canada. Sexual dimorphism in mature animals may be most evident in tail length, with males possessing a tail a minimum of two to three times longer than that of females of a comparable curved carapace length. However, penis display during handling can also readily identify a male

turtle. Penis extrusion has been observed in snapping turtles (*Chelydra serpentina*) (de Solla et al. 2001. Chelon. Cons. Biol. 4:187–189), however, only in animals held off the ground. We observed partial, or complete penis extrusion in five of seven male *D. coriacea* that were captured at sea as part of a satellite telemetry study. Penis display was in all cases associated with full plastron contact with a tagging platform mounted on a boat. Penis display by leatherbacks in this context likely represents a displacement behaviour associated with handling (deSolla et al, *op. cit.*), rather than a sexual or defensive response. As sexual dimorphism in tail length is more apparent in mature and large subadult turtles, penis display may be of greatest utility in the identification of juvenile males.

I thank H. Fricker, B. Fricker, B. Mitchell, M. Rideout, and K. Martin for field assistance. The observations reported here were made during fieldwork associated with a leatherback turtle satellite telemetry project supported by the Department of Fisheries and Oceans, the Nova Scotia Leatherback Turtle Working Group, World Wildlife Fund Canada, Environment Canada, and the National Marine Fisheries Service (USA).

GLYPTEMYS MUHLENBERGII (Bog Turtle). **DIET**. Bog Turtles are omnivorous, opportunistic feeders that apparently eat whatever acceptable food source is most abundant and easiest to obtain (Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press, Washington, D.C. 313 pp.). In Virginia, Bog Turtles have been observed eating tent caterpillars (*Malacosoma* sp.), earthworms (Annelida), and unidentified berries (Mitchell 1994. Reptiles of Virginia. Smithsonian Institution Press, Washington, D.C. 352 pp; Carter 1997. M.S. Thesis. Virginia Polytechnic Institute and State University, Blacksburg, Virginia, 79 pp.).

In the summer of 1999, Virginia Department of Game and Inland Fisheries (VDGIF) biologists gathered additional information on *G. muhlenbergii* diet in Virginia during a mark-recapture population study in Floyd County. On 11 August 1999, a 9+ year-old, adult female *G. muhlenbergii* (max CL: 92 mm, max PL: 82 mm, mass: 122.5 g) deposited a fecal pellet in a holding bucket. Initial study of the scat revealed beetle exoskeleton parts which Richard Hoffman of the Virginia Natural History Museum in Martinsville, Virginia, identified as the remains of a Japanese Beetle (*Popillia japonica*), a common, exotic pest species.

On 18 August 1999, a 10+ year-old, adult female turtle (max CL: 95 mm, max PL: 86 mm, mass: 126.0 g) from a different location in Floyd County, also deposited a fecal pellet while being held for data collection. Initial study of this scat sample revealed over 30 small dark and light brown seeds. On average, the larger, dark brown seeds were 0.035 mm long and 0.016 mm wide and were considered mature. The smaller, lighter brown seeds on average were 0.020 mm long and 0.014 mm wide and were considered immature. Tom Wieboldt, Assistant Curator of the Virginia Tech Herbarium in Blacksburg, Virginia, identified the source for both types as low-bush blueberries (*Vaccinium vacillans*), a common woodland shrub species.

Based on the amount of these food items in the two scat samples, both Japanese beetles and low-bush blueberries can be considered components of *G. muhlenbergii* diet in Virginia.

Special thanks go to Michael Pinder of VDIGF and Eric Wilhelm of USDA-APHIS (formerly of VDIGF) for their assistance and to Richard Hoffman and Tom Wieboldt for their time and expertise.

MALACLEMYS TERRAPIN TERRAPIN (Northern Diamond-back Terrapin) **DIET.** *Malaclemys terrapin* is an inhabitant of salt marshes, tidal creeks, and estuaries ranging from Cape Cod, Massachusetts south to the Florida Keys and as far west as Texas. This species is especially well adapted for crushing mollusk shells, gastropods, and crabs (*Littorina*, *Mytilus*, *Uca*, and *Callinectes*) (Ernst et al. 1994 Turtles of the United States and Canada, Smithsonian Inst. Press, 578 pp.) but is a generalist that will also eat plant material, fish, and insects. Here we report a possible new prey item for the northern subspecies, *Malaclemys t. terrapin*, which suggests scavenging tendencies

In July 2000, a gravid female Diamondback Terrapin was found on Stone Harbor Boulevard, Stone Harbor, New Jersey (39°03'N, 74°46'W) and was taken to the nearby Wetlands Institute of Stone Harbor, New Jersey. The mortally wounded individual was euthanized and necropsied for parasite analysis (Werner et al. 2002 Bull. New Jersey Acad. Sci. 47[2]:21–24). Upon gross analysis of the large intestine, two live black larder beetle larvae (Dermestidae: *Dermestes ater*) were discovered. During the 2000 nesting season, 66 mortally wounded females were euthanized and necropsied but this was the only individual that showed evidence of predation on dermestid beetle larvae. Because dermestid beetles feed on carrion, we speculate that these individual larvae were feeding on carrion in the salt marsh at the time of ingestion by the terrapin. It is thus possible that the female *Malaclemys* had been recently feeding on carrion and ingested the two larvae. The carrion may have been floating on surface waters or perhaps the female was feeding on land before nesting. It is unknown whether or not *Malaclemys* will feed on land (R. Wood, pers. comm.). It is also unknown how these larvae survived the digestion process.

We thank Roger Wood for insight on feeding habits, and Michael Thomas and John Kingsalver for larvae identification.

Submitted by **DANA J. EHRET**, Florida Museum of Natural History, PO Box 112170, Gainesville, Florida 32611-2710, USA (e-mail: dehret@flmnh.ufl.edu), and **RALPH E. WERNER,** The Richard Stockton College of New Jersey, Pomona, New Jersey 08240, USA.

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). **AQUATIC BEHAVIOR**. *Terrapene carolina triunguis* is primarily terrestrial, although there have been reports of aquatic behavior, such as moving into water during the heat of summer and entering water to drink (Dodd 2001. North American Box Turtles: A Natural History. Univ. Oklahoma Press, Norman, Oklahoma. 231 pp.). We observed four instances of aquatic behavior in

this species during the summer and fall of 2002.

The first observation occurred on 4 June 2002, on the Current River (Carter County, Missouri, USA). A box turtle was swimming at the surface of the river. The turtle was ca. 5 m from the east bank, in 2–3 m of water and was swimming toward the west bank. The east bank was a bluff bank ca. 10–15 m in height. It is unknown if the turtle had fallen from the bluff or had entered the river at a point upstream. The turtle was kept as a voucher specimen for a herpetofaunal inventory for the National Park Service (NPS, ASUMZ 27039) and was later measured with calipers (height = H, 70 mm; bridge width = BW, 97 mm, and carapace length = CL, 134 mm).

A second observation of aquatic behavior occurred at Wilson's Creek National Battlefield (Greene County, Missouri) on 23 June 2002. During a dip net survey of an ephemeral woodland pond (ca. 10 m diam), we found a box turtle in 23 cm of water. The turtle did not appear to be foraging, as the water was stagnant and did not contain any invertebrates or other vertebrates. The turtle was partially submerged in the water. When we approached, the turtle moved into a head-down position and began "swimming" to the bottom. Once there, it began to wedge itself into the mud and held this position on the bottom. Shortly thereafter, we began timing the duration of the submergence. After 13 min and 17 sec, the turtle extended its neck to the surface of the water to breathe. The turtle was also kept as a voucher specimen for the NPS herpetofaunal inventory (ASUMZ 27076) and later measured (H = 74 mm; BW = 93 mm; CL = 131 mm).

A third observation was on 23 July 2002 on the Current River (Shannon County, Missouri). A box turtle was retrieved from the bottom of the Current River. The turtle was "sitting" on large cobble substrate and was ca. 10 m from the bank at a depth of ca. 2 m. This turtle was retained as a NPS herpetofaunal inventory voucher specimen (ASUMZ 27169) and later measured (H = 75 mm; BW = 107 mm; CL = 144 mm).

A fourth observation was on 21 October 2002, on the North Fork of the White River (Ozark County, Missouri). The turtle was moving along the edge of the river, ca. 1–2 m from the bank. The turtle was photographed and released back into the water. Upon release the turtle sought refuge within a root wad at the edge of the shoreline. The turtle remained on the surface of the water hidden beneath the vegetation until we left the area.

We thank the Department of Biological Sciences, Arkansas State University, for use of facilities and equipment. The National Park Service provided funding to SET for the field research. The Missouri Department of Conservation authorized the scientific collection permit (MDC 11419, Wildlife Collector's Permit, 2002). Malcolm L. McCallum reviewed the manuscript and offered helpful editorial comments on this manuscript.

LACERTILIA

AMEIVA FESTIVA (Central American Racerunner). **PREDATION**. Species of the lizard genus *Ameiva* typically are among the most important terrestrial carnivorous lizards in Neotropical assemblages as they eat both invertebrates and vertebrates (Vitt and Zani 1996. J. Herpetol. 30:110–117). Orthopterans (crickets, katydids, and roaches) and arachnids (spiders) dominate *A. festiva* diet, but they also eat small amphibians and other lizards may be consumed (Savage 2002. The Herpetofauna of Costa Rica: A land between two continents, between two seas. The University of Chicago Press, 510 pp.; Vitt and Zani, *op. cit.*). Savage (*op. cit.*) noted that *A. festiva* feeds on small amphibians, but did not state which species are consumed. Here I augment observations of predation on anurans with the first report of an adult of *A. festiva* eating a juvenile Turbo White-lipped Frog, *Leptodactylus poecilochilus*.

I made the observation over a 15-min period ca. 0830 h on 20 June 2002, while conducting an amphibian census at the La Selva Biological Station (La Guaria Annex), Heredia, Costa Rica (10°26'N, 83°59'W) in a pasture 2 m from the edge of secondary forest. I encountered an adult *A. festiva* (ca. 105 mm SVL) swallowing a juvenile (ca. 20 mm SVL) *L. poecilochilus,* which already had its head in the lizard's mouth. Upon approach, the lizard ran toward the forest edge, were it sat for ca. 10 min on leaf litter and continued to swallow the frog up to its groin. At that point, I was able to see clearly the white stripe on the frog's posterior thigh, an unequivocal trait that distinguishes *L. poecilochilus* (Savage, *op. cit.*). The lizard then disappeared into the forest, and I was unable to find it again.

Juveniles of *L. poecilochilus* are common in the small puddles that form in the pastures as a result of livestock activity. Thus, the edge between pastures and forests in this region might be important foraging grounds for *A. festiva*, especially when recruitment of juvenile *L. poecilochilus* is at its peak.

Submitted by **EDUARDO TORAL C.**, Universidad de Costa Rica, San Pedro de Montes de Oca, San José, Costa Rica; e-mail: guashote@yahoo.com.

DIPLOGLOSSUS LEGNOTUS (NCN). **REPRODUCTION.** No reproductive data are available for the recently described anguid lizard, *Diploglossus legnotus* (Campbell and Camarillo 1994. Herpetologica 50:193–209). Here we provide the first data on reproduction for *D. legnotus*.

On 2 August 1998, LCM collected a gravid female (96.4 mm SVL, 105.4 mm tail length, 17.5 g; upper head, body and tail were brown, distinct black markings were arranged in irregulars vertical bars on sides, a distinct red ventrolateral band extended from axilla to groin hence onto basal third of tail; sides of neck between posterior infralabials and insertion of forelimb were yellowish). The lizard was collected 3.5 km W Xocoyolo, Municipality of Cuetzalan del Progreso, Puebla (19°59.432'N, 97°33.325'W; elev. 1355 m). The locality is a cattle ranch bordered by cloud forest, and a stream runs along the cloud forest margin. The female was collected under a fallen tree trunk on a slope with abundant fallen trees. On 23 September 1998, the female gave birth to seven young (mean SVL 32.5 mm, SD 1.7 mm, range: 29.4–34.2 mm; mean tail length 37.8 mm, SD 2.3 mm, range 35.8–42.5 mm; mean mass 0.55 g, SD 0.07 g, range: 0.46–0.64 g). After parturition, the female weighed 12.2 g. All seven neonates were bright green with nine white dorsal stripes, a red ventrolateral band, and a blue tail.

Reproductive data on Mexican *Diploglossus* species are scarce, but available information indicates that the three recognized species are viviparous. *Diploglossus rozellae* gives birth to 3–5 young during the interval May–July (Alvarez del Toro 1982. Los Reptiles de Chiapas. 3rd ed. Instituto de Historia Natural, Tuxtla Gutiérrez, Chiapas. 248 pp.), but the clutch size we report for *D. legnotus* is at the high end of the range for *D. enneagrammus*, which has 3–7 young in June (Canseco-Márquez 1996. Estudio Preliminar de la Herpetofauna en la Cañada de Cuicatlán y Cerro Piedra Larga, Oaxaca. Unpublished Thesis. Universidad Autónoma de Puebla. 180 pp.; P. Heimes, pers. obs.).

The female *D. legnotus* (EBUAP 1655) was deposited in the herpetological collection of Benemérita Universidad Autónoma de Puebla, México. Support for field work was provided by grant from CONABIO (number FB444/L283/97) to G. Gutiérrez-Mayén, and SEMARNAT provided the necessary collecting permits.

MANRÍQUEZ-MORÁN**, Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México. A.P. 70-153, México, D.F. 04510, México, and **GUADALUPE GUTIÉRREZ-MAYÉN**, Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México.

ELGARIA PAUCICARINATA (San Lucan Alligator Lizard). **ENDOPARASITES.** *Elgaria paucicarinata* is restricted to the Cape Region of Baja California Sur (Grismer 2002. Amphibians and Reptiles of Baja California Including its Pacific Islands and the Islands in the Sea of Cortés. University of California Press, Berkeley. 399 pp.). To our knowledge, no reports exist of endoparasites from this species. The purpose of this note is to report the presence of four nematode species from *E. paucicarinata*.

Seven *E. paucicarinata*, 4 males and 3 females (mean SVL = 92 mm ± 9 SD, range: 82–105 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM 92711–12, 92714, 92718–19, 99441, 109371) were examined for helminths. The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The body cavity was also examined. Except for LACM 109371, all lizards were infected. Four species of nematodes, *Cosmocercoides variabilis* (infection site: small and large intestines); *Physaloptera retusa* (stomach); *Oswaldocruzia* sp. (small intestine); and *Rhabdias* sp. (lung) were found. Prevalence (infected lizards/lizards examined X 100), mean intensity (mean helminth number/infected lizards) and range are as follows: *Cosmocercoides variabilis* (57%, 6.0 ± 3.1 SD, range: 1–11), *Physaloptera retusa* (57%, 4.8 ± 4.1 SD, range: 1–10), *Oswaldocruzia* sp. (29%, 1.5 ± 0.71 SD, range: 1–2), and *Rhabdias* sp. (14%, 1.0). Helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland as: *Cosmocercoides variabilis* (USNPC 93511); *Physaloptera retusa* (USNPC 93509); *Oswaldocruzia* sp. (USNPC 93512); *Rhabdias* sp. (USNPC 93510).

Cosmocercoides variabilis is known from various amphibians and reptiles of North America (Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1–325; Goldberg et al. 2000. Southwest. Nat. 45:362–366; Goldberg and Bursey 2002. Bull. South. California Acad. Sci. 101:118–130) and *Physaloptera retusa* is known from amphibians and reptiles of North and South America (Goldberg et al. 2004. Comp. Parasitol. *in press*). *Elgaria paucicarinata* represents a new host record for *C. variabilis* and *P. retusa* and Baja California a new locality record. The numerous species of *Oswaldocruzia* and *Rhabdias* have more limited distributions (see Baker, *op. cit*). This is the first report of *Oswaldocruzia* and *Rhabdias* in *Elgaria paucicarinata* and may represent undescribed species.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu), **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu), and **KENT R. BEAMAN**, Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: heloderma@adelphia.com).

GEKKO SUBPALMATUS (NCN). **REGIONAL INTEGUMENTARY LOSS**. An adult male *Gekko subpalmatus* (Yale Peabody Museum of Natural History, slide collection YPM.M.01007) was collected by Dustin Sigler on 27 July 2000 from a stone wall at Tai Zhu Ao, Nan Ao Island, Guandong Province, Peoples Republic of China (23°26'00"N, 117°03'00"E). When handled, the specimen's skin tore easily in a manner consistent with regional integumentary loss (RIL), an anti-predator escape strategy employed by geckos in at least 9 different lineages (Bauer et al. 1989. J. Exp. Biol. 145:79–102). The resulting wound extended over ca. 10% of the back and was associated with little or no bleeding, as is typical in defensive integumentary loss. The animal survived without special care or obvious distress at least 6 days, until euthanized. This is the first record of this anti-predator defense in the species, and in the genus *Gekko*, which includes at least some species (e.g., *G. gecko*) with mechanically strong, tough skins (Bauer et al. 1989, *op. cit.*). Similar intrageneric variation in this ability has been noted in the African geckos of the genus *Pachydactylus* (Bauer et al. 1993. S. Afr. J. Zool. 28:192–197). Although *G. subpalmatus* has a broad range within southern China, RIL has only been documented on Nan Ao, a small island (106 km^2) in the South China Sea. This is consistent with the general trend among geckos for this strategy to evolve chiefly in insular contexts (Bauer and Russell. 1992. Ecol. Ethol. Evol. 4:343–358). In at least one other species of gekkonid, *Thecadactylus rapicauda*, some evidence of notable intraspecific variation in skin fragility exists, with insular populations more prone to RIL than those from continental regions (Bauer et al. 1989, *op. cit.*). Possibility of a parallel situation in *G. subpalmatus* needs investigation.

Submitted by **GREGORY J. WATKINS-COLWELL**, Yale Peabody Museum of Natural History, Department of Vertebrate Zoology, 170 Whitney Avenue, P.O. Box 208118, New Haven, Connecticut 06520, USA (e-mail: Gregory.Watkins-Colwell@yale.edu), and **AARON M. BAUER**, Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA (e-mail: aaron.bauer@villanova.edu).

LEPIDOBLEPHARIS XANTHOSTIGMA (Orange-tailed Gecko). **ENDOPARASITES.** *Lepidoblepharis xanthostigma* is a small diurnal gecko that inhabits leaf litter and occurs from southeastern Nicaragua, northwestern Costa Rica to northern Colombia (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas, University of Chicago Press, Chicago, 934 pp.). To our knowledge, no reports exist of endoparasites from this species. The purpose of this note is to report the presence of a larval acanthocephalan in a *L. xanthostigma* from Costa Rica.

Ten female *L. xanthostigma* (mean SVL = 33 mm ± 4 SD, range: 28-40 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles (LACM 148083–084, 148092, 148105, 148107, 148109–113), collected in Guanacaste and Puntarenas provinces, Costa Rica in 1964, 1965, and 1973 were examined for helminths. The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The body cavity was also examined. One acanthocephalan cystacanth was found in the stomach of LACM 148083. The cystacanth was cleared in a drop of undiluted glycerol on a glass slide, examined with a compound microscope and assigned to the family Oligacathorhynchidae. Prevalence (infected lizard/lizards examined X 100) was 10%. The cystacanth was deposited in the United States National Parasite Collection, Beltsville, Maryland as (USNPC 93433).

Lizards are known as paratenic (transport) hosts of species of the acanthocephalan family Oligacathorhynchidae (Schmidt 1985. *In* Crompton and Nickol [eds.], Biology of the Acathocephala, pp. 273–305. Cambridge University Press, Cambridge, UK). Development to the adult acanthocephalan occurs when the lizard is eaten by a predator. A list of lizards serving as paratenic hosts for oligacanthorhynchid cystacanths is in Bolette (1997. Southwest. Nat. 42:232–236). *Lepidoblepharis xanthostigma* feeds primarily on spiders as well as isopods and mites (Lieberman 1986. Acta Zool. Mex. 15:1–72). Infection likely occurs when *L. xanthostigma* ingests prey containing acanthocephalan larvae. An oligacanthorhynchid cystacanth in *L. xanthostigma* is a new host record.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu) and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu).

LEPIDOPHYMA SYLVATICUM (Madrean Tropical Night Lizard). **REPRODUCTION.** Tropical night lizards (genus *Lepidophyma*) are rarely seen, so data on their natural history is sparse. Available information indicates that members of this genus are viviparous, have litters of 1–8, display peak reproductive activity in winter, carry developing young during winter and spring, and give birth in early summer (Bezy and Camarillo 2002. Contrib. Sci. Los Angeles County Mus. Nat. Hist. 493:1–41). Here, we augment the few reproductive data on *Lepidophyma* with the first report for *L. sylvaticum.*

On 28 April 1998, LCM collected a gravid female *L. sylvaticum* (98.7 mm SVL, tail 62.0 mm [40.0 mm regenerated]) in the Sierra Norte de Puebla, ca. 2 km S of San Miguel Tzinacapan, Municipality of Cuetzalan del Progreso, Puebla, Mexico (20°00.603'N, 97°32.485'W; elev. 1140 m). The female was collected under large rocks in an open area on a hill within disturbed cloud forest. After being maintained in captivity, this female gave birth to five young on 24 June 1998. These averaged 33.4 mm SVL (SD 0.5 mm, range: 33.0–34.2) and 0.64 g (SD 0.02 g, range: 0.62–0.66). Despite the nearly two-month captive interval, the parturition date and litter size are within the known range of variation for other species of *Lepidophyma*.

The female (EBUAP 2061) was deposited in the herpetological collection of Benemérita Universidad Autónoma de Puebla, México. Support for field work was provided by grant from CONABIO (number FB444/L283/97) to G. Gutiérrez-Mayén, and SEMARNAT provided the necessary collecting permits.

Submitted by **LUIS CANSECO-MÁRQUEZ**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México (e-mail: lcm@correo.unam.mx), and **NORMA L. MANRÍQUEZ-MORÁN**, Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México. A.P. 70-153, México, D.F. 04510, México.

NANNOSCINCUS GRACILIS (New Caledonian Gracile Dwarf Skink). **VOCALIZATION**. Among lizards, complex vocalizations including distinctive advertisement and distress calls are largely restricted to gekkotans (Gans and Maderson 1973. Amer. Zool. 13:1195–1203; Frankenberg and Werner 1992. Acta Zool. Lilloana 41:45–62). Among autarchoglossan families, vocalization has been reported for scattered representatives in several families, and in the case of certain lacertids, it may be used in territorial interactions (Böhme et al. 1985. Bonn. Zool. Beitr. 36:337–354). In the family Scincidae, only defensive vocalizations have been reported. Loud emphatic vocalizations have been reported for the New Guinea crocodile skink *Tribolonotus gracilis* (Cogger 1972. Zool. Meded. 47:202–210; O'Shea 1991. Brit. Herpetol. Soc. Bull. 37:15–17) and have been linked to parental defense of young (Hartdegen et al. 2001. Contemp. Herpetol. 2001[2] [http://dataserver.calacademy.org/herpetology/herpdocs/ch/2001/2/index.htm]). Less dramatic defensive squeaks have been reported in a few other skink species (e.g., *Euprepes* [formerly *Mabuya*] *bensonii*; Barbour and Loveridge 1930. *In* Strong [ed.], The African Republic of Liberia and the Belgian Congo, pp. 769–785. Harvard University, Cambridge, Massachusetts), although the validity of some records has been questioned (Mertens 1946. Abh. Senckenberg. Naturf. 471:1–108) and in other species, distress vocalizations appear to be rare (e.g., *Chalcides ocellatus;* Frankenberg and Werner 1992, *op. cit.*). Most records of skink vocalization, however, derive from Pacific region lygosomines, including representatives of the Australian genera *Ctenotus*, *Egernia*, *Eremiascincus*, *Eulamprus*, *Gnypetoscincus*, and *Saproscincus* (Greer 1976. Aust. Nat. Hist. 18:428–433; Covacevich and McDonald 1980. Mem. Qld. Mus. 20:95–101; Annable 1983. Herpetofauna 14:80–82) and the New Zealand genus *Oligosoma* (Werner 1973. Israel J. Zool. 22:204–205; Thomas 1985. *In* Grigg et al. [eds.], Biology of Australasian Frogs and Reptiles, pp. 17–22. Surrey Beatty, Chipping Norton). We here report another in-

stance of scincid defensive vocalization in a New Caledonian endemic, *Nannoscincus gracilis*.

Nannoscincus gracilis, the largest species (to 49 mm SVL) in a genus of small skinks, is a cryptic form found in humid forests up to 1100 m elevation in central New Caledonia (Bauer and Sadlier 2000. The Herpetofauna of New Caledonia. Society for the Study of Amphibians and Reptiles, Ithaca. xii + 310 pp.). Thirteen *N. gracilis* were collected underneath logs and stones in montane forest at 950-1040 m on Pic Ningua, 17.0 km south of Nakaré, Province Sud, New Caledonia (21°44'S, 166°09'E) on 26–27 September 2002. Specimens from this locality are morphologically distinctive and may be specifically distinct from other populations. All specimens made faint but distinctive squeaks when handled. Vocalizations were elicited by grasping or handling the body and were accompanied by writhing and occasional biting, both typical in the genus. Squeaking was noted both at initial capture and subsequently when specimens were handled in the laboratory.

Whether vocalizations are employed to deter potential predators (large arthropods, birds, larger skinks and geckos) or they function in intraspecific interactions is unclear. That most skinks known to vocalize are lygosomines occurring in Australia or on Pacific islands implies some underlying phylogenetic and/or ecological commonality. However, the species for which vocalization has been documented do not form a monophyletic group, and this behavior has been too poorly documented to attribute any special meaning to this apparent geographical bias.

Nannoscincus specimens were collected under permit 6034-2075/DRN issued by the Direction des Ressources Naturelles of the Province Sud, New Caledonia and exported under permit 6034-2330/DRN of the same authority. Specimens (Field numbers AMB 7338–7344, 7373–7378) will be deposited in the California Academy of Sciences and Australian Museum collections.

NOROPS PENTAPRION (Lichen Anole). **ENDOPARASITES.** *Norops pentaprion* is a small to moderate-sized anole (adult males 70–79 mm standard length, adult females 57–63 mm standard length) found in lowland forest zones from the Isthmus of Tehuantepec, Mexico to Colombia (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas, University of Chicago Press, Chicago. 934 pp.). To our knowledge, no reports exist of endoparasites from this species. The purpose of this note is to report the presence of two species of nematodes in *N. pentaprion* from Costa Rica.

Four (1 female, 3 males) *N. pentaprion* (mean SVL = 66 mm ± 3 SD, range: 63–70 mm) were examined for helminths from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles: LACM 148382–383, 148392–393, collected in Puntarenas and Guanacaste provinces, Costa Rica in 1967, 1980, 1973, and 1974, respectively. The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The body cavity was examined as well. The only infected anole was LACM 148383. Four *Skrjabinelazia intermedia* were found in the stomach; 32 *Cyrtosomum longicaudatum* were found in the large intestine. Prevalence (infected lizard/lizards examined X 100) was 25%. The nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland as *Skrjabinelazia intermedia* (USNPC 93507) and *Cyrtosomum longicaudatum* (USNPC 93508).

Skrjabinelazia intermedia is previously known from *Tropidurus spinulosus* and *T. torquatus* from Brazil (Vicente 1981. Atas Soc. Biol. Rio de Janeiro 22:7–18). *Norops pentaprion* represents a new host record for *S. intermedia.* Costa Rica is a new locality record. *Cyrtosomum longicaudatum* is previously known from *Ctenosaura similis* from Costa Rica (Brenes and Bravo-Hollis 1960. Sobretiro del Libro Homenaje al Dr. Eduardo Caballero y Caballero, pp. 451–464, Mexico, D.F.) and from Honduras and Mexico (Caballero Deloya 1971. An. Inst. Biol. Univ. Nac. Autón. México 42:29–33). It has also been found in *Anolis equestris, A. luteogularis, A. baracoae, Chamaeleolis chamaeleonides, C. porcus, Leiocephalus cubensis, L. stictigaster, L. carinatus,* and *Hemidactylus brooki* from Cuba (Barus and Coy Otero 1968. Folia Parasit. 15:41–45; Barus and Coy Otero 1969. Helminthologia 10:329–346; Coy Otero and Barus 1973. Folia Parasit. 20:297–305; Coy Otero and Barus 1979. Acta Sci. Nat. Brno 13:1–3) and *Anolis garmani* from Jamaica (Bundy et al. 1987. J. Helminthol. 61:77–83). *Norops pentaprion* represents a new host record for *C. longicaudatum*.

SCINCELLA LATERALIS (Ground Skink). **PREDATION**. Accounts of spiders preying on vertebrates are infrequent. However, some spiders are known to take lizards. For example, Cokendolpher (1977. J. Arachnol. 5:184) observed an *Argiope aurantia* eating a *Eumeces laticeps*, and Corey (1988. J. Arachnol. 16:392–393) found an *Anolis carolinensis* in the chelicerae of a *Lycosa ammophila*. This note details the first observation of a wolf spider feeding on the Ground Skink, *Scincella lateralis*.

At 1330 h on 15 March 2003, we encountered a small (ca. 4 cm SVL) *S. lateralis* struggling with a *Hogna carolinensis* (ca. 3 cm head–abdomen length) under a piece of tin at the Old Sabine Wildlife Management Area, Smith County, Texas (32°35'33"N, 95°21'26"W). The spider held the skink by the neck with its fangs. The two animals wrestled for ca. 5 min before the skink stopped moving. When the spider released the skink, we discontinued observations. About 30 min later, we returned to the site and the spider was still near the dead skink.

Don Killebrew verified the identity of the spider.

FOSTER**, and **JAMES B. TOWEY**, Department of Biological Sciences, Eastern Illinois University, Charleston, Illinois 61920, USA.

STENOCERCUS AZUREUS (NCN). **REPRODUCTION.** Reproductive data on *Stenocercus azureus* are sparse (Cei 1993. Mus. Reg. Sci. Nat. Torino, Monogr. 14:1–949) and data are lacking for Uruguay. Here, we provide preliminary information on clutch size and egg dimensions for Uruguayan *S. azureus*.

We report data on three adult females in the Colección Zoología Vertebrados, Reptiles (ZVC-R), Facultad de Ciencias, Montevideo. External measurements were obtained after preservation; data on eggs were obtained by dissection. Calixto Fuques collected ZVC-R 176 at Tres Cruces, Departamento Artigas (30°27'S, 56°48'W; elev. 150 m) in January 1955; Alejandro Olmos collected ZVC-R 4656 at Potrero "La Invernada," Estancia de Castro "El Tapado," Arerunguá, Departamento Salto (31°38'S, 56°44'W; elev. 250 m) on 9 January 1990; and ZVC-R 1619 has a collection locality of Uruguay without further data.

Female ZVC-R 176, 79.4 mm SVL (112.6 mm tail, 21.4 g), has 8 eggs (mean dimensions = 14.2 x 8.0 mm, ranges: 13.8–14.8 x 6.2–10.1 mm; mean mass: 0.47 g, ranges: 0.43–0.50 g); female ZVC-R 1619, 69.6 mm SVL (115.4 mm tail, 12.9 g), has 6 eggs (mean dimensions = 15.7 x 8.9 mm, ranges: 15.20–16.05 x 8.6–9.4 mm; mean mass: 0.62 g, ranges: 0.52–0.69 g); and female ZVC-R 4656, 80.2 SVL (121.8 mm tail, 24.8 g), has 9 eggs (mean dimensions = 15.2 x 8.5 mm, ranges: 15.30–18.60 mm x 7.1–9.6 mm; mean mass: 0.69 g, ranges: 0.49–1.01 g).

Torres-Carvajal (2004. Herpetol. Rev. 35:172) recently reported a clutch size of 6 for one *S. azureus*. Although the locality was not indicated, that individual was also from Uruguay but lacked specific locality data (O. Torres-Carvajal, pers. comm.). Clutch sizes of 6–9 in *S. azureus* based on Uruguayan specimens are larger than known clutches sizes for all other species of *Stenocercus*, which range from 2 to 4 (Torres-Carvajal 2000. Univ. Kansas Mus. Nat. Hist. Sci. Pap. [15]:1–38). The two available collection dates are for January, which might indicate summer reproduction.

We thank Melitta Meneghel for assistance in dissection.

TROPIDURUS TORQUATUS (Calango). **PREDATION.** Many reptiles are bird prey (e.g., Terres 1991. The Audubon Society Encyclopedia of North American Birds. Wing Books, New York, New York. 1109 pp.). Although broadly distributed across Cerrado and Atlantic Forest domains in Brazil (Rodrigues 1987. Arq. Zool. São Paulo 31:105–230), records of predators on *Tropidurus torquatus* are lacking. Here, I report an instance of Burrowing Owl predation on *T. torquatus* from central Brazil.

On 26 September 2002 in the municipality of Caldas Novas (17°50'S, 48°36'W), Estado do Goiás, Brazil, Ariovaldo A. Giaretta found a gravid female *T. torquatus* (66 mm SVL) inside the nest chamber of a Burrowing Owl, *Speotyto cunicularia*. The *T. torquatus* was found dead with a small gash on its throat, but was otherwise intact. We presume that the owl made the throat gash during the predation episode.

Bird predation on lizards is common (e.g., Palacios et al. 1997. Herpetol. Rev. 28:204–205; Franz 2001. Herpetol. Rev. 32:253). As *T. torquatus* is both abundant and widespread, we would expect it to be prey for at least some birds. Although many aspects of the biology of *T. torquatus* have been studied (e.g., diet—Bergallo and Rocha 1994. Austral. J. Ecol. 19:72–75; thermal ecology—Bergallo and Rocha 1993. Amphibia-Reptilia 14:312–315; spatial patterns—Giaretta 1996. Herpetol. Rev. 27:80–81), a lack of records of predation seems peculiar. This observation represents the first record of predation on *T. torquatus*.

The female *T. torquatus* (AAG-UFU 1196) is deposited at the Museu de Biodiversidade do Cerrado in the Universidade Federal de Uberlândia, Estado do Minas Gerais, Brazil. We thank Ariovaldo A. Giaretta for critically reading the manuscript.

Submitted by **MARCELO N. DE C. KOKUBUM**, Laboratório de Ecologia e Sistemática de Anuros Neotropicais (e-mail: mnckokubum@hotmail.com), and **WILLIAM ZACCA**, Programa de Pós-Graduação em Ecologia e Conservação de Recursos Naturais, Universidade Federal de Uberlândia, 38400-902, Uberlândia, Minas Gerais, Brazil.

TROPIDURUS TORQUATUS (Calango). **SAUROPHAGY.** *Tropidurus torquatus*, a tropidurid lizard ranging from Brazil to Argentina (Rodrigues 1987. Arq. Zool. 31:205–230), has been reported to have an insect-dominated diet (Bergallo and Rocha 1994. Austral. J. Ecol. 19:72–75; Fialho et al. 2000. J. Herpetol. 34:325–330; Juliano et al. 2002. Herpetol. Rev. 33:54–55). Frugivory (Figueira et al. 1994. Biotropica 26:295–301), herbivory (Fialho et al., *op cit.*), and cannibalism of adults on juveniles has also been reported (Kiefer and Sazima 2002. Herpetol. Rev. 33:136), but predation on other lizards is unrecorded. Hence, we describe an instance of predation by *T. torquatus* on the teiid *Cnemidophorus ocellifer* from central Brazil.

At 1000 h on 13 September 2002, we found an adult *Tropidurus torquatus* (ca. 220 mm total length [TL]) consuming an adult (ca. 100 mm TL) *C. ocellifer* (Teiidae) at Fazenda Limoeiro, municipality of Cumari, Estado de Goiás (18°03'S, 48°03'W). When first seen, the *C. ocellifer* was alive in the mouth of the predator, immobile, and was being held by the posterior part of the body; 6 minutes after we first saw the encounter, the *C. ocellifer* was swallowed. During this time, the *C. ocellifer* twice attempted to escape twice and continued to struggle until the *T. torquatus* bit it, and it stopped moving.

Cnemidophorus ocellifer is an active forager, whereas *T. torquatus* is a territorial sit-and-wait predator (Gandolfi and Rocha 1998. Amphibia-Reptilia 19:319–323; Giaretta 1996. Herpetol. Rev. 27: 80–81). The movement of a small lizard within the territory of an adult *T. torquatus* may elicit a predatory act. This observation indicates that *T. torquatus* has a broader trophic niche than previously thought.

We thank A. A. Giaretta for critically reading the manuscript and N. F. Lemos for providing logistic support.

ZONOSAURUS LATICAUDATUS (NCN). **PREDATION**. The genus *Zonosaurus* (Gerrhosauridae) consists of rather large, diurnal lizards endemic to Madagascar. Although members of the genus typically feed on invertebrates (unpubl. data), here I report several cases of *Z. laticaudatus* feeding on frogs.

On 3 April 2000, at the Kirindy forest station 60 km N of Morondava in western Madagascar, I found a large *Z. laticaudatus* biting the neck of a large (ca. 45 mm SVL) adult *Laliostoma labrosum* (Mantellidae) in an open area of the forest station. It shook the frog until it went limp and started to swallow it head first. On 4 January 2000, similar behavior was observed for another individual of *Z. laticaudatus* with an adult (ca. 35 mm SVL) *Boophis doulioti* (Mantellidae) on the forest floor near a breeding pond. Lastly, on 21 January 1999, a *Z. laticaudatus* was observed successfully preying on several recently metamorphosed froglets (ca. 10 mm SVL) of *Aglyptodactylus laticeps* (Mantellidae) at the edge of a breeding pond. All events occurred on sunlit gaps not covered by canopy. These observations suggest that frogs may form a significant part of the prey base for *Z. laticaudatus*.

I thank Kathrin Dausmann, the 'Ministère des Eaux et Forêts' (Antananarivo) and the German Academic Exchange Service (DAAD) for support. Research permit was issued by the Ministère des Eaux et Forets (N° 217/MEF/SG/DGEF/DGDRF/SCB).

SERPENTES

AGKISTRODON CONTORTRIX (Copperhead). **PREDATION**. On 6 September 2003, an adult male Copperhead (*Agkistrodon contortrix*) fitted with a Holohil Ltd. SB-2 transmitter was radiotracked by one of us (NEH) at the Madison County Wildlife Management Area, Ozark Natural Science Center, in northwest Arkansas as part of an ongoing study. The tracker, however, was lead to an adult Speckled Kingsnake (*Lampropeltis getula holbrooki*) rather than the expected Copperhead. The male kingsnake was captured and measured (108.0 cm TL; 621.6 g) at the time of capture. The Copperhead was located alive on 4 September 2003 by one of us (SJB), and captured on 15 July 2003; it measured (70.0 cm TL; 216.1 g, including the 5.0 g transmitter). Therefore, by subtraction the Copperhead was ca. 53.3% of the kingsnake's body mass, and 64.8% of the kingsnake's total length. The kingsnake was held in captivity at 27°C. The copperhead's PIT-tag and scales were defecated on 18 September 2003, and we presumed that two weeks after defecation digestion was complete. The post-defecation mass of the kingsnake was 463.8 g. Based on this measurement the Copperhead represented a meal that was ca. 46.6% of the final body mass of the kingsnake. The actual relative prey mass for the kingsnake probably falls somewhere between the two estimates (46.6–53.3%).

The Common Kingsnake (*Lampropeltis getula*) is a well-known predator of snakes, including Copperheads (Fitch 1960. Autecology of the Copperhead. Univ. Kansas Publ. Mus. Nat. Hist., 13). Previous reports of predation on Copperheads by snakes in the wild have included Racers (*Coluber constrictor*), Common Kingsnakes (*Lampropeltis getula*), and Eastern Coral Snakes (*Micrurus fulvius*) (summarized in Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. Soc. Stud. Amphib. Reptil., Contrib. Herpetol. 6, 614 pp.). Few reports of Common Kingsnake predation on snakes have supplied the relative prey size. A juvenile Black Kingsnake (*Lampropeltis getula nigra*) consumed a Brown Snake (*Storeria dekayi*) and an Eastern Wormsnake (*Carphophis amoenus*), which combined represented 112% of the length of the kingsnake (Byrd and Jenkins 1996. Herpetol. Rev. 27:204). Additionally, a juvenile Desert Kingsnake (*Lampropeltis getula splendida*) consumed a Plains Black-headed Snake (*Tantilla nigriceps*) that was estimated to be 82% of the kingsnake's length (LaDuc et al., 1996. Herpetol. Rev. 27:25). Three Rough Greensnakes (*Opheodrys aestivus*) greater than 500 mm SVL were consumed by *L. g. holbrooki*, which each represented a conservative 58%, 69%, and 75% of the Kingsnake's length (Plummer 1990. J. Herpetol. 24:327–328). The Copperhead in this note represents the largest reported relative ophidian meal size by mass for a *Lampropeltis getula* as far as we could determine from the literature.

Submitted by **CHAD E. MONTGOMERY** (e-mail: cemontg@uark.edu), **NICK E. HAERTLE**, and **STEVEN J. BEAUPRE**, University of Arkansas, Department of Biological Sciences, Fayetteville, Arkansas 72701, USA.

AGKISTRODON PISCIVORUS (Cottonmouth). **DIET**. The reported diet of *A. piscivorus* consists mainly of vertebrate prey including occasional vertebrate carrion (Burkett 1966. Univ. Kansas Pub. Mus. Nat. Hist. 17:435–491). Previous accounts have described parts of birds in Cottonmouth stomachs, including feathers of large birds, unidentified bird bones, the head and neck of an adult egret, and intact waterbirds (egret and ibis) (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. Contributions to Herpetology, No. 6, SSAR. 620 pp.). Here we report the identification of the shoulder girdle and wing of a Blue-winged Teal (*Anas discors*) ingested by a female *A. piscivorus*.

On 16 May 2002, 2103 h, a female *A. piscivorus* (64 cm SVL, 10.9 cm TL, 348.8 g) was captured in the Tuskegee National Forest, Macon County, Alabama, USA, and held overnight for measurements and additional processing. Upon closer inspection the following morning, it was noted that the snake had a series of protruding bulges at its mid-body. The specimen was radiographed after attempts to palpate the prey item were unsuccessful. The radiograph (deposited in the Herpetology Collection at Auburn University; AUM 4566) shows a complete right shoulder girdle (coracoid and scapula) and wing (humerus, ulna, radius, carpometacarpus, carpels) that was compared against skeletal specimens in the ornithological collections of the Florida Museum of Natural History of 30 species that occur in the capture area. Based on relative length and thickness of the humerus and ulna,

the wing was identified to the family Anatidae. Within Anatidae, fine level osteological comparison allowed us to identify the wing as a Blue-winged Teal (UF 23494, UF 23497 - Coracoid: distal end [especially processus procoracoideus]; Humerus: proximal head [esp. fossa pneumotricipitalis, crista bicipitalis, and crista pectoralis], distal head [esp. condylus ventralis and condylus dorsalis]; Ulna: proximal head). Terminology follows Baumel et al. (1979. Nomina Anatomica Avium, Academic Press).

Because of the strength of avian shoulder girdles, it is unlikely that the snake was able to remove the wing from a carcass by pulling. We presume that the present specimen scavenged the wing that had been separated from the rest of the carcass and dropped by another predator. We were unable to locate additional evidence of the *A. discors* carcass near the capture area.

We thank David Harding of Parkway Animal Hospital, Auburn, Alabama for the donation of services and the radiograph; David Steadman, Florida Museum of Natural History, University of Florida, Gainesville, Florida for use of comparative skeletal materials and verification of the bird identification; and Craig Guyer for comments and discussion.

Submitted by **MATTHEW I. WILLIAMS** (e-mail: miwilliams@auburn.edu), **ROGER D. BIRKHEAD**, **PAUL R. MOOSMAN, JR.,** and **SCOTT M. BOBACK**, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849, USA.

AGKISTRODON PISCIVORUS PISCIVORUS (Eastern Cottonmouth). **DIET**. The Cottonmouth (*Agkistrodon piscivorus*) is an opportunistic predator that feeds on invertebrates, fish, amphibians, reptiles, birds and small mammals (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio. 614 pp.; Mitchell 1994. The Reptiles of Virginia. Smithsonian Institution Press, Washington. 368 pp.). Lepidopteran larvae, cicadas, grasshoppers, and damselflies, have been reported as insect prey (Gloyd and Conant 1990, *op. cit.*; Ernst et al. 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.). Here we describe the first reported incidence of *A. piscivorus* consuming a moth cocoon. On 31 July 2003, in Gum Swamp, Beech Island, South Carolina, USA, an *A. piscivorus* (533 mm SVL) was collected by one of us (XG). It was left in a snake bag overnight, and during that time regurgitated a Southern Leopard Frog (*Rana sphenocephala*) and an intact lepidopteran cocoon that was identified by one of us (DLW) as a Luna Moth (*Actias luna*, Saturniidae). The cocoon was possibly ingested secondarily, via the frog. However, because movement is important in releasing feeding behavior in anurans (Borchers et al. 1978. J. Comp. Physiol. 152:241–249; Freed 1988. Herpetologica 44:18–24), the frog likely did not feed on a non-motile cocoon. Interestingly, Smith (1997. Herpetol. Rev. 28:153) reported an instance of *A. contortrix* regurgitating a moth cocoon (*A. luna*) seven days after being caught, suggesting that the cocoon was not digestible. The moth was deposited in the Savannah River Ecology Laboratory Museum.

Submitted by **XAVIER GLAUDAS**, University of Georgia's Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA (e-mail: xavier@srel.edu), and **DAVID L. WAGNER**, Ecology and Evolutionary Biology, U-Box 43, University of Connecticut, Storrs, Connecticut 06269-3043, USA (e-mail: dwagner@uconnvm.uconn.edu).

BOA CONSTRICTOR (Boa Constrictor). **KLEPTOPARASITISM**. On 7 August 2002, at about 1000 h, within the compound at the Man O'War Bay Cottages, Charlotteville, Tobago, an adult Ameiva (*Ameiva ameiva*, ~25 cm SVL) was observed tugging at something that was caught in a tuft of grass adjacent to the beach. One of us (TM) approached within 1 m of the lizard and saw that it had a dead anole (Richard's Anole, *Anolis richardii*, ~15 cm SVL) in its mouth. Presumably, the *A. ameiva* captured the *A. richardii*, but we did not observe this. After a few seconds, the Ameiva pulled the anole from the grass and carried it by the neck beneath a small ornamental bush in the center of the compound. As the Ameiva darted under an overhang in the bush, a juvenile *Boa constrictor* (~91 cm SVL) that was hidden in the leaf litter struck and snatched the anole from its mouth. The Ameiva briefly tugged at the anole but eventually released it and scurried away. The boa then constricted the anole and began to swallow it head-first.

Intra- and interspecific kleptoparasitism, defined as stealing food from another (Ruxton and Moody 1997. J. Theor. Biol. 186:449–458), is well documented among certain predatory birds and mammals. Intraspecific kleptoparasitism among captive squamate reptiles at high densities is documented in controlled environments but rarely in the field (Cooper and Pérez-Mellado 2003. Amphibia-Reptilia 24:219–224). Boa Constrictors are moderately abundant in the upland forest surrounding Charlotteville, but are rarely seen along the coastal areas where *A. ameiva* and *A. richardii* are very abundant (J. D. Hardy, pers. comm.). This observation is possibly the first interspecific record of opportunistic kleptoparasitism in squamate reptiles.

We thank Jerry D. Hardy for the opportunity to study on Tobago, and Roy McDiarmid and Harry Greene for comments on the manuscript.

WILKINSON,** U.S. Geological Survey, Patuxent Wildlife Research Center, P.O. Box 37012, National Museum of Natural History, Washington, DC 20013-7012, USA (e-mail: wilkinson.fiona@nmnh.si.edu).

BOTHRIECHIS SCHLEGELII (Eyelash Viper). **PREY/PREDATOR WEIGHT RATIO** and **DIET.** Viperid snakes feed on exceptionally large prey items relative to their body size (Cundall and Greene 2000 *In* K. Schwenk [ed]. Feeding: Form, Function, and Evolution in Tetrapod Vertebrates, pp. 293–333. Academic Press, San Diego, California). Data collected from pitvipers include the largest prey/predator ratios reported for snakes, with two examples exceeding 1.5 (Greene 1983. Amer. Zool. 23:431–441; Mulcahy et. al. 2003. Herpetol. Rev. 34:64). In this account we report a prey/predator ratio for *Bothriechis schlegelii* that rivals the largest published values, and documents a previously

undescribed prey item. Greene (1989 *In* F. Almeda and C. M. Pringle [eds.], Tropical Rainforests: Diversity and Conservation, pp. 259–274. California Academy of Sciences, San Francisco) characterizes *B. schlegelii* as an "extreme diet generalist" which is known to take frogs, lizards, birds, bats, and small mammals (rodents and mouse opossums). Other authors have published similar information describing the diet of *B. schlegelii* in general terms (Campbell 1998. The Amphibians and Reptiles of Northern Guatemala, the Yucatan, and Belize.Univ. of Oklahoma Press. 380 pp; Lee 2000. A Field Guide to the Amphibians and Reptiles of the Mayan World. Cornell Univ. Press. 402 pp; Savage 2002. The Amphibians and Reptiles of Costa Rica. The Univ. of Chicago Press. 934 pp.). An anecdotal account published by Hardy (1994. Sonoran Herpetol. 7:108–113) provides the only instance where prey item (*Norops limifrons*) was identified to species.

On 29 June 2003, 1215 h, a subadult female *B. schlegelii* (360 mm SVL, 423 mm TL, 19 g), was located outstretched along a woody vine (~0.75 m above ground level). The snake was noticeably distended from a recent feeding; it was captured and palped about 7 h post-capture. The prey item was a male *Thecadactylus rapicaudus* (SVL 118 mm SVL, 125 mm TL, 28 g), which results in a prey/predator ratio of 1.47. This snake was captured about 20 m elev. in Atlantic Lowland Tropical Moist Forest (Holdridge et.al. 1967. Life Zone Ecology. Tropical Science Center, San José, Costa Rica. 206 pp.) at a mainland site in Bocas del Toro Province, Panamá. The snake was released at the site of capture the following day, and the prey item was preserved and housed in the collection of the Institute for Tropical Ecology and Conservation, Bocas del Toro Biological Station, Panamá.

We thank Scott M. Boback, Craig Guyer, and Thomas R. Jones for their comments.

Submitted by **SHAWN D. LINDEY** (e-mail: lindesd@hotmail.com) and **GEOFFREY G. SORRELL**, Department of Biological Sciences, Auburn University, Alabama 36849, USA (e-mail: sorregg@auburn.edu).

BOTHRIOPSIS TAENIATA or ***BOTHROPS TAENIATUS*** (Speckled Forest Pitviper). **JUVENILE SIZE**. The Speckled Forest Pitviper (see taxonomic comment below) is a geographically variable, arboreal species with a wide distribution in South America east of the Andes (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Ithaca, New York, Cornell University Press, 425 pp.). We are unaware of reports on juveniles from populations in Ecuador. Five individuals were collected in the vicinity of Tena, Province of Napo, Ecuador (~ 1°S, 77°50'W; 300–900 m elev.) in February and April 1978, months with the highest precipitation: Instituto Nacional de Higiene y Medicina Tropical [INHMT] 219 (collected by Antonio Tapiry on 10 February 1978; 30 cm TL), 328 (collected by Anibal Rodríguez on 18 April 1978; 25 cm total length), 330 (collected by Antonio Freire L. on 19 April 1978; 30 cm TL), 335 (collected by Agusto Tanguinde on 22 April 1978; 30 cm TL), 337 (collected by Manuel Shigmango on 23 April 1978; 25 cm total length). Three additional juveniles of similar size were collected in the same area on 23 April 1982 (INHMT 1003–05, collected at El Napo by Antonio Freire L.). The largest adults out of a series of 30 specimens received by the Instituto Nacional de Higiene y Medicina Tropical were two snakes from Tena, which measured 150 cm total length each (INHMT 226–27).

Because generic assignment of this pitviper species is controversial (see papers in Schuett et al. [eds.] 2002. Biology of the Vipers, Eagle Mountain Publishing, Eagle Mountain, Utah, 580 pp.), we present the two most widely recognized combinations to facilitate information retrieval.

Submitted by **ANTONIO FREIRE L.**, Departamento Serpentario, Instituto Nacional de Higiene y Medicina Tropical "Leopoldo Izquiéta Pérez," Casilla 3961, Guayaquil, Ecuador, and **ULRICH KUCH**, Sektion Herpetologie, Forschungsinstitut und Naturmuseum Senckenberg, Senckenberganlage 25, 60325 Frankfurt am Main, Germany (e-mail: U.Kuch@em.uni-frankfurt.de).

BOTHROPS ASPER (Terciopelo or Equis). **DIET**. This large species of pitviper inhabits a variety of habitats from northeastern Mexico through Central America to northwestern South America, where its range along the Pacific Coast extends into northernmost Peru (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York; Tello 1998. *In* Wust [ed.], La Zona Reservada de Tumbes. Lima, Australis South America, pp. 81–87). Published records of prey types characterize this species as opportunistic. Prey is primarily ectothermic in juvenile stages, whereas endothermic prey is consumed as they reach a sufficient size to swallow large and bulky animals. Considering its extensive geographical distribution and common occurrence, specific records of prey items of *B. asper* are relatively rare. They include orthopterans, centipedes, crayfish, frogs, anoles, geckos, skinks, snakes (including conspecifics), birds, marsupials, rodents, and rabbits (reviewed in Campbell and Lamar, *op cit.*). Here we report on the stomach contents of four *B. asper* from the coastal lowlands and the Pacific versant of the Andes in Ecuador, where this species is widely distributed. The specimens are deposited in the herpetological collections of the Instituto Nacional de Higiene y Medicina Tropical, Guayaquil (INHMT) and the Museo de Zoología de la Pontificia Universidad Católica del Ecuador, Quito (QCAZ). On 23 January 1998, a subadult *B. asper* (631 mm SVL, 88 mm TL, INHMT, uncatalogued) collected by Cesar Morán at Finca Escorpión, Puerto Inca 2, Province of Guayas, Ecuador, contained a cotton rat (*Sigmodon peruanus*, 173 mm SVL, 83 mm TL; QCAZ 3669). Body mass of the ethanol preserved snake was 200 g before dissection; after dissection, wet mass of the snake and its prey were 100 g and 75 g, respectively (prey/predator mass ratio ~ 0.75). A subadult *B. asper* (620 mm SVL, 116 mm TL; INHMT 4095) collected in La Maná, Province of Cotopaxi, Ecuador (ca. 79°13'W, 0°57'S), contained an unidentified, partly digested Muridae species (> 73 mm SVL, 99 mm TL; QCAZ 3670). Wet mass after dissection of the ethanol preserved specimens were 75 g and 20 g, respectively (prey/predator mass ratio > 0.25). On 18 April 1991, an adult male *B. asper* (1054 mm SVL, 170 mm TL; INHMT 2336) collected by José Lema in Sacramento, Cantón Pallatanga, Province of Chimborazo, Ecuador (ca. 79°02'W, 2°10'S, 1200–1500 m elev.), contained an unidentified, rat-sized rodent. A juvenile *B. asper* (ca. 35 cm TL; INHMT 4083) from Las Naves, Province of Bolívar, Ecuador (ca. 79°15'W, 1°17'S), had mammalian hair in its stomach;

thus, endothermic prey is confirmed in juveniles. Prey/predator mass ratios are within the limits reported for other species of *Bothrops*, from which ratios of up to 1.3–1.6 are recorded (Greene 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 107–118. Selva, Tyler, Texas; Sazima 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp.199–216. Selva, Tyler, Texas).

We thank Luis A. Coloma of QCAZ for reviewing the manuscript.

BOTHROPS LOJANUS (Lojan Lancehead). **DIET**. This poorly known pitviper species inhabits arid, temperate regions of the Andes in southern Ecuador, and has been found primarily at its type locality, the vicinity of Loja (Provincia de Loja and adjacent parts of the Provincia de Zamora-Chinchipe, Ecuador); however, a record exists from Saraguro (Provincia de Loja), 40 km N of Loja. The known vertical distribution of *B. lojanus* is 2100–2500 m elevation, and its preferred habitat is apparently montane dry forest (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York). Here we present for the first time data on the diet of *B. lojanus*. On 19 July 2002, 1245 h, we found an adult male *B. lojanus* (272 mm SVL, 35 mm TL, ca. 16 g) dead on the Pan-American Highway, about 3 km N of Loja (Cantón Loja, Provincia de Loja, Ecuador; 79°15'11.2"W, 3°56'22.5"S, 2340 m elev.). An adult female microteiid lizard (*Pholidobolus annectens*; 64 mm SVL, 50 mm TL, ca. 1.9 g) was protruding from various parts of the damaged anterior body of the snake. The *P. annectens* appeared to be essentially undigested, but its position indicated that it had been completely swallowed before the snake was killed. Road construction workers informed us that they had encountered the snake when removing bunch grass locally known as "sigse" (*Cortaderia* sp., according to them the preferred shelter of *B. lojanus*), and killed and thrown it onto the highway just before our arrival. The surrounding disturbed habitat of rocky grassland and pastures dominated by bunch grasses suggested a potential natural vegetation of montane dry forest. Surface temperature of sun-exposed rocks, soil, and asphalt highway was 30.5°C; air temperature 1 m above the ground was 20°C in full sun with a brisk wind. The *B. lojanus* and the *P. annectens* are deposited in the herpetological collection of the Museo de Zoología de la Pontificia Universidad Católica del Ecuador, Quito (QCAZ 6018 and 6019, respectively).

BUNGARUS CANDIDUS (Malayan Krait). **DIET**. The Malayan Krait (*Bungarus candidus* Linnaeus, 1758) is a nocturnal elapid that is widely distributed in mainland Southeast Asia, the Malayan Peninsula, Sumatra, Java, and Bali. Captive *B. candidus* are reported to prefer snakes as prey, especially freshwater species (Van Hoesel 1959. Ophidia Javanica. Bogor, Mus. Zool. Bogoriense, Pertjetakan Archip., 188 pp.; Campden-Main 1970. A Field Guide to the Snakes of South Vietnam. Washington, D.C., Division of Amphibians and Reptiles, U.S. National Museum, Smithsonian Institution, 114 pp.). Many captive specimens readily accept synbranchid eels (*Monopterus albus*), laboratory mice, and rats (Kuch 2001. Herpetol. Bull. 75:10–14; Kuch and Schneyer 1991. Sauria [E] 1:7–14). Specific records on the diet of wild specimens are rare; they include skinks (*Mabuya* sp. and unidentified remains; N = 3: Lim in Tweedie 1983. The Snakes of Malaya. Singapore, Singapore Natl. Printers, 167 pp.; Slowinski. 1994. Herpetol. Rev. 25:51–53), caecilians (*Ichthyophis* sp.; N = 1: Grossmann and Schäfer. 2000. Sauria 22:45–46), and adult, mouse-size rodents (hair and incisors; N = 2: Kuch, *loc. cit.*), but snakes are not reported.

Here we report a colubrid snake (*Elaphe radiata*) as a natural prey item for *B. candidus*. Both prey and predator are deposited in the herpetological collection of the National Museum of Natural History, Smithsonian Institution, Washington, D.C., USA (USNM). All measurements were taken from the ethanol-preserved specimens. An adult male *B. candidus* (960 mm SVL, 132 mm TL; USNM 167595) was collected at "Ca Lu, Vietnam", in January 1969 by William T. McBighan. This locality name most likely refers to the village of Ca Lu, prior to 1971 located at 16°41'N, 106°55'E on the main road from Quang Tri City to Khe Sanh, at the base of Dong Ca Lu mountain ridge, a predominantly limestone part of the Annamese Cordillera (R. I. Crombie, pers. comm.).

The specimen of *B. candidus* was captured while eating the juvenile *E. radiata* (414 mm SVL, 89 mm TL; USNM 167596). The maximum diameter of the head of the *B. candidus* and the *E. radiata* (head width at the posterior angle of the jaw) was 19.3 mm and 9.1 mm, and the greatest diameter of the body (in both snakes midbody in dorsoventral axis) was 19.7 and 11.1 mm, respectively. Body mass of the ethanol-preserved snakes was determined to be 241.5 g for the *B. candidus* and 19.7 g for the *E. radiata* (prey/predator mass ratio ~ 0.08).

We thank Ronald I. Crombie of USNM for documenting the collection site of these snakes and reviewing the manuscript.

DENDROASPIS POLYLEPIS (Black Mamba). **DEFENSIVE BEHAVIOR**. The Black Mamba (*Dendroaspis polylepis*) is well known to show defensive behavior, such as raising the front part of the body and spreading a narrow hood (Ionides 1969. Mambas and Man-Eaters: A Hunter's Story. Postscript by Dennis Holman, Mayflower, London, pp. 1–236). On 27 February 2002, while conducting field studies in Botswana, we observed an unusual defensive behavior by a female *D. polylepis* that, to our knowledge, has not been recorded in this species. On 26 February at ca. 2100 h as we spotlighted, we sighted the snake climbing an acacia tree (5 m) at a private game ranch situated in the southeastern part of the country. Nocturnal activity by mambas is poorly understood and rarely recorded; this is the first individual we encountered active at night. After a minor chase the snake was captured, measured (ca. 2.5 m TL), and sexed, whereupon it was placed into a cloth bag to be photographed the next day. On 27 February, at about 0800 h, the snake was removed from the bag and allowed to climb another small tree where it was to be photographed. The snake moved in the tree and after about 15 minutes it descended to the ground. Because we also wanted photographs of it on the ground we approached it to within a distance of ca. 2 m whereupon it displayed its typical defensive behavior (i.e., raising of the front part of the body off the ground and spreading of a narrow hood). We remained still and the snake lost interest in us and moved into an open area. One of us investigated how the snake would react if it were constantly cornered (it was not allowed to approach any of the nearby thickets, which were ca. 10 m away). The snake again reacted by raising the front part of the body and spreading a hood. However, walking around the snake at a distance of about 2 m for 5–10 min made it impossible for it to reach the thickets. At the end of this exercise, the snake displayed a very peculiar defensive behavior. It coiled up and hid its head under the coils and raised the tail tip about 20–30 cm above the ground. The tail was constantly moving in the middle of the coiled snake, a behavior very similar to what has been described as defensive behavior in the garter snake *Thamnophis radix* (Arnold and Bennett 1984. Anim. Behav. 32:1108–1118). We are certain that this behavior was not caused by heat stress. Such tail displays have been suggested to divert attacks to a more 'disposable' part of the body compared to attacks directed to the head, which is common among several avian and mammalian predators (Jackson 1979. Copeia 1979:169–172). It is interesting to note that in a very thorough study of temporal and spatial ecology of *D. polylepis* in South Africa, individual identity of the specimens studied was based upon on scarring and bits of tail missing (Phelps 2002. Herpetol. Bull 80:7–19). Thus, perhaps the latter injuries might have been due to predator attacks on individuals displaying behavior similar to tail-raising observed by us.

Submitted by **THOMAS MADSEN** and **BEATA UJVARI**, School of Biological Sciences A08, University of Sydney, NSW 2006, Australia and Department of Animal Ecology, Ecology Building, Lund University, S-223 62 Lund, Sweden; e-mail: Thomas.Madsen@zooekol.lu.se.

ENULIOPHIS SCLATERI (Colombian Long-tailed Snake). **REPRODUCTION.** *Enuliophis sclateri* is a colubrid snake that occurs in evergreen forests from Nicaragua to central Colombia and in southwestern Costa Rica to eastern Panama; it is diurnal and fossorial (Savage 2002. The Amphibians and Reptiles of Costa Rica; A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). There is, to my knowledge, no information on its clutch sizes. Herein I present information on ovarian activity from *E. sclateri* from Costa Rica deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California.

A female *E. sclateri* (LACM 150616) collected in 1991 (month unknown) in Puntarenas Province, Costa Rica (270 mm SVL) contained two oviductal eggs (mean egg length: 15.0 mm). The above represents the first reported data on potential clutch size for *E. sclateri*.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

ENULIUS FLAVITORQUES (Pacific Long-tailed Snake). **REPRODUCTION**. *Enulius flavitorques* is a colubrid that occurs from Jalisco, Mexico to Colombia; it is diurnal and fossorial (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). There is, to my knowledge, no information on its clutch size. Herein I present information on ovarian activity in *E. flavitorques* from Costa Rica deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California.

A female *E. flavitorques* (LACM 150628; 280 mm SVL) collected in the summer of 1961 from San José Province, Costa Rica, contained three enlarged ovarian follicles (mean follicle length: 14.7 mm ± 1.5 SD, range: 13.0–16.0 mm) which would have presumably ovulated. The above represents the first reported information on potential clutch size in *E. flavitorques*.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA: sgoldberg@whittier.edu.

LAMPROPELTIS ALTERNA (Gray-banded Kingsnake). **DIET.** Although *Lampropeltis alterna* has been documented to feed on iguanids, teiids, anurans, and small rodents (Miller 1979. A Life History of the Gray-banded Kingsnake, *Lampropeltis mexicana alterna* in Texas. Master's thesis. Sul Ross State University, Texas. 91 pp.; Tennant et al. 1998. A Field Guide to Texas Snakes. Gulf Publ. Co., Houston, Texas. 211 pp.), detailed knowledge of its natural diet is lacking. Here, we report bird eggs in the diet of *L. alterna* for the first time. On 13 June 1997, at ca. 0100 h we found an adult female *L. alterna* crossing FM-170 (Presidio County, Texas, USA) 1 mi. W of the bridge in Panther Canyon. A row of five bulges, each approximately the size of a small ping-pong ball, were evident mid-body. The specimen was placed in a bag and several hours later five eggs were regurgitated. Although two eggs were slightly digested (as evidenced by their flaking shell casings) the outer membrane remained undamaged. The other three eggs

were in perfect condition, indicating that the clutch was consumed very recently. Dissection of one egg revealed a nearly fully developed Scaled Quail (*Callipepla squamata*). We thank Alan Tennant for identifying the bird.

MASTICOPHIS FLAGELLUM PICEUS (Red Racer). **CARRION FEEDING.** DeVault and Krochmal (2002. Herpetologica 58:429–436) summarized 35 literature reports of natural snake scavenging (spanning at least 24 snake species and assorted carrion) to show that snakes utilize carrion more often than commonly believed. Not unexpectedly, these reports reveal that snakes generally use olfaction to locate carrion, and they suggest that some snake species forage specifically for carrion.

On 24 July 1974 between 0700 and 1030 h I observed three unusual instances of opportunistic carrion feeding by two or three *Masticophis flagellum piceus* at a field collectors' campsite in Whitewater Canyon, Riverside County, California (33°57.422'N, 116°38.650'W, 536 m elev.). During the previous evening (23 July 1974) researchers at the camp prepared about a dozen museum study skins of local rodent specimens including field mice (*Peromyscus*) and pocket mice (*Perognathus* and *Chaetodipus*), all < 35g live mass. We skinned the animals, removed the heads, opened the abdominal cavities to evaluate reproductive condition, and discarded the carcasses randomly in sparse desert vegetation along a nearby road embankment. During the night the skinless carcasses desiccated rapidly in the high temperatures and extremely low humidity. They were also contaminated with desert gravel and the hardwood sawdust used during preparation.

The next morning (24 July 1974) at 0700 h, a *M. f. piceus* (ca. 1200 mm TL) was outstretched in open view in full sunlight along the above embankment, rapidly engulfing one of the desiccated mouse carcasses. An attempt to catch the snake failed and it escaped rapidly, still grasping the mouse carcass. Air temperature at 0700 h was 28°C, and ground temperature in direct sun was ca. 40°C. Three hours later we noticed a second *M. f. piceus* (1175mm TL) engulfing a very dry mouse carcass at the same spot on the embankment where the first snake had been. The ground temperature (determined later) at the site was 44°C, and the shaded-bulb air temperature was 42°C. About 20 minutes later we saw a third *M. f. piceus* (1180 mm TL) outstretched and engulfing a mouse carcass < 2 m from the spot where the first snakes were seen. I collected the second and third specimens with dust shot and deposited them in the UC Davis Museum of Zoology (cat nos. 5331–5332). The stomachs of both specimens were empty, but I cannot be certain that either collected snake was not the specimen seen at 0700 h.

Cowles (1946, Herpetologica 3:121–122) and Small et al. (1994. Herpetol. Rev. 25:28) reported natural carrion feeding by *M. f. piceus*, respectively, on a poorwill (*Phaelaenoptilus nuttali*) in an advanced state of putrefaction and on a road-killed Glossy Snake (*Arizona elegans*). Our observations and others support DeVault and Krochmal's (2002) contention that carrion is normal forage for some snake species, and they underscore the role of olfaction in foraging even in snakes thought to rely primarily on prey movement and other visual cues.

Submitted by **SEAN J. BARRY**, Section of Evolution and Ecology, University of California, Davis, California 95616, USA; present address: ENTRIX, 7919 Folsom Blvd., Suite 100, Sacramento, California 95826, USA; e-mail: sbarry@entrix.com.

MICRURUS DISTANS (West Mexican Coral Snake). **TREE CLIMBING**. Snakes of the genus *Micrurus* are secretive and largely fossorial, and are often found under cover objects such as leaves, stones, and logs (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms. Krieger Publ., Malabar, Florida). To our knowledge, there are no records of arboreality for this species. On 24 September 2001, at 1230 h, while conducting a survey on the herpetofauna of the Cuixmala-Chamela Biosphere Reserve on the coast of Jalisco, México, we observed a *M. distans* (790 mm TL) climbing a mature tree at ca. 4.5 m above the ground. The tree was part of a small patch of remnant dry forest immersed in a matrix of livestock grazing plots in different stages of regeneration. Air temperature was 29.1°C and humidity was 84.6%. Upon discovery the snake climbed down the tree and disappeared under the ground litter (specimen was photographed while climbing down). This observation suggests that this typically ground-dwelling species of coral snake may occasionally climb trees, perhaps to hunt prey not readily available on the ground. Two previous publications report the presence of *M. distans* in the area we describe herein but make no reference to arboreal habits (García and Ceballos 1994. Guia de Campo de los Reptiles y Anfibios de la Costa de Jalisco, Mexico, Fundación Ecologica de Cuxmala and IB UNAM, Mexico:184 pp.; and Ramírez-Bautista 1994. Manual y Claves Ilustradas de los Anfibios y Reptiles de la Región de Chamela, Jalisco, México. Cuadernos IB UNAM [23]:1–127).

We thank Javier Alvarado Díaz, Alfredo Estrada Virgen, Miriam Quintero-Mora, and Karla Grissel Jaimez Novas for assistance in field work and the Coordinación de Investigación Científica, UMSNH project 5.5 for financial assistance. We thank E. N. Smith for his editorial help and Antonio Hernández for photographic work.

NINIA PSEPHOTA (Cope's Coffee Snake). **REPRODUCTION.** *Ninia psephota* is a colubrid that occurs in evergreen forests in Costa Rica and Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago. 934 pp.). There is, to my knowledge, no information on clutch size in *N. psephota*. Herein I present information on two egg clutches

from *N. psephota* deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California.

One *N. psephota* (LACM 153772; 315 mm SVL) collected 16 March 1959 in Cartago Province, Costa Rica, contained 4 oviductal eggs (mean egg length: 11.9 mm ± 1.4 SD, range: 10.4–13.7 mm). A second *N. psephota* (LACM 153766; 321 mm SVL) collected 20 November 1963 in Cartago Province, Costa Rica, contained 4 oviductal eggs (mean egg length: 12.8 mm ± 0.6 SD, range: 12.2–13.4 mm).

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California, 90608, USA; e-mail: sgoldberg@whittier.edu.

PSEUSTES POECILONOTUS (Puffing Snake). **REPRODUCTION.** *Pseustes poecilonotus* is a common, diurnal colubrid that ranges from San Luis Potosí, Mexico to Amazonian Peru, Bolivia, and Brazil (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). There is, to my knowledge, no information on clutch size. Information on an egg clutch from *P. poecilonotus* from Costa Rica is presented herein, based on material deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California.

A female *P. poecilonotus* (1429 mm SVL; LACM 153978) collected 25 July 1963, San José Province, Costa Rica, contained seven enlarged follicles (mean follicle length: 33.4 ± 4.8 mm SD, range: 25–40 mm), which presumably would have been ovulated. These data are the first reported on female reproduction in *P. poecilonotus.*

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

PHILODRYAS VIRIDISSIMUS (Green Palm Snake). **FEEDING ATTEMPT**. Members of the genus *Philodryas* (Colubridae) consume a wide variety of prey including amphibians, snakes, lizards, birds, and mammals (Silva and Filho 1999. Herpetol. Rev. 30:170). However, the specific predation habits of the arboreal *Philodryas viridissimus* are not thoroughly known. Herein we describe an instance of predation by *P. viridissimus* on a bat.

On 1 January 2003, at 1235 h, an adult *Philodryas viridissimus* (140 cm SVL; 36 cm TL; 350 g) was observed attempting to consume a bat (Phyllostomatidae; 98 mm total body length, 15 mm tip of ear to base of skull, 66 mm length of forearm, 16 mm length of hind-foot), on a forest trail within the 10,000-ha rainforest of Reserva Amazonica. This reserve exists on the north bank of the Rio Madre de Dios, 15 km ENE of Puerto Maldonado, Departamento de Madre de Dios, Peru (12°32.295'S, 69°03.211'W; 200 m elev.). The snake was on the ground not moving, with the bat approximately one-third in its mouth. The bat appeared too large for the snake to consume; red irritations present along the jaw of the snake suggested it was being overstretched. Many flies and wasps were present around the exposed part of the carcass, indicating that the bat had been dead for several hours. Using the coils of its body the snake attempted to force the bat further into its mouth, however this produced no visible progress. A portion of the bat's forelimb was pressing outward conspicuously from inside of the snake's throat and appeared as if it could easily puncture the skin. After 40 minutes of observation and no visible sign of progress by the snake, it was captured. The snake immediately released the bat and coiled into a strike position. The mouth of the snake was mangled and bloody from trying to swallow a prey item that was seemingly much too large.

Upon examining the bat carcass a strong odor of decay was noticed and the joints of the bat were very stiff. The skin around the abdominal region of the bat was open, exposing the abdominal muscles. The body of the bat was too decomposed to make confident identification beyond family in the field. The alignment of the snake's lower jaw was slightly out of place and remained that way until its release near the site of capture on 3 January 2003, at 1300 h. A photographic voucher of the specimen was deposited in the Herpetology Collection of the Department of Biology, University of Wisconsin-Stevens Point.

Submitted by **CLINT R. V. OTTO**, Department of Biological Sciences Towson University, 8000 York Road, Towson, Maryland 21252-0001, USA (e-mail: cotto1@towson.edu), and **GABRIEL J. MILLER**, Department of Biology, University of Wisconsin Stevens Point, Wisconsin 54481, USA (e-mail: gmill711@uwsp.edu).

SIBON ANTHRACOPS (Cope's Snail Sucker). **REPRODUCTION.** *Sibon anthracops* is a colubrid snake that occurs in lowlands from Guatemala to Costa Rica (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). Kofron (1987. J. Herpetol. 21:210–225) reported three females (locality not given) each containing three enlarged yolked follicles indicating clutches of three eggs. One female from El Salvador had follicles 17.9–19.8 mm (length) on 2 July and presumably would have ovulated later that month (Kofron, *op. cit.*). The purpose of this note is to present additional information on egg clutches from *S. anthracops.*

Four female *S. anthracops* from Guanacaste Province, Costa Rica were examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA. One female (LACM 154110, 386 mm SVL) collected 2 July 1964 contained three enlarged ovarian follicles (mean length = 18.4 mm ± 0.72 SD, range: 18–19 mm). One female (LACM 154116, 400 mm SVL) collected August-October 1973 contained five oviductal eggs (mean length = 23.4 mm ± 2.6 SD, range: 21–27 mm) which represents the largest reported egg clutch for *S. anthracops.* Histological examination of ovarian tissue revealed that LACM 154123 (365 mm SVL) collected 31 May 1974 was not undergoing yolk deposition (= secondary yolk deposition *sensu* Aldridge 1979. Herpetologica 35:256–261) while LACM 154126 (355 mm SVL) collected 29 October 1973 was undergoing yolk deposition and represents the smallest reported reproductively active *S. anthracops* female.

Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

SIBON ARGUS (NCN). **DIET**. Snakes of the Neotropical genus *Sibon* are described as mollusk and gastropod specialists (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.), although Greene (1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley, 351 pp.) refers to them as "goo-eaters." Kofron (1987. J. Herpetol. 1987:210–225) dissected 151 specimens of three species of *Sibon*, and found 4.6% of specimens with gut contents of slugs and an earthworm. Herein we describe the first report of *Sibon argus* feeding on eggs from an arboreal species of anuran, and provide further evidence that the vernacular name goo-eater is suitable.

Sibon argus is patchily distributed in lowland evergreen rainforests from southeastern Costa Rica to eastern Panama (Savage and McDiarmid 1992. Copeia 1992:421–432). While conducting herpetological surveys at Parque Nacional Omar Torríjos, El Copé, Coclé Province, Panama (8°40'N, 80°37'17"W), we observed an adult *S. argus* (360 mm SVL) wrapped around a branch, 1.5 m above a small headwater stream at 2000 h on 5 June 2002. The snake's head was hidden within a clump of moss on a lower branch ca. 10 cm below the snake's body. When we gently pulled the snake away from the moss, we saw it was in the process of swallowing several *Centrolenella prosoblepon* eggs, and had five Gosner Stage 18 (Gosner 1960. Herpetologica 1960:183–190) eggs clinging to the sides of its mouth. We saw ca. 10 additional eggs in the moss clump. We identified the snake as *S. argus* (Savage and Villa 1986. Herpetofauna of Costa Rica. Society for the Study of Amphibians and Reptiles, Ithaca, New York. 207 pp.) and then released it at the point of capture.

Sibon argus is a common snake at this site and is often seen along streams. In nine months of survey work at El Copé during 1999–2002, all *S. argus* we captured (N = 71) were alongside stream habitats. At night these snakes are often seen slowly moving along branches while tongue flicking moss clumps and leaf undersides, apparently foraging. We hypothesize that the snakes are searching for arboreal frog eggs. Nine species of stream breeding centrolenids and one leaf breeding hylid (*Phyllomedusa lemur*) occur at this site, and were actively breeding during our survey work.

On 19 May 2001, one of us (MJR) found unidentifiable green jelly in stomachs of 4 of 12 dissected *Sibon nebulatus* 14 km NE of Dominical, Puntarenas Province, Costa Rica. These snakes were collected DOR 15 m from a breeding pond of *Agalychnis callidryas* following an explosive breeding episode in which hundreds of frogs were calling and depositing eggs. We suspect that the distinctive green jelly was the remains of the green eggs typical of *Agalychnis* egg masses. Near the Dominical area, 26 other *S. nebulatus* gut contents did not contain the green jelly, including 11 collected from the above-mentioned pond on other nights. This suggests that *S. nebulatus* may opportunistically feed on these eggs when they are abundant. *Sibon* may feed on frog eggs more than has been previously recognized, but because eggs are delicate and become unrecognizable when ingested they may be under represented in gut contents.

Submitted by **MASON J. RYAN** and **KAREN R. LIPS**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901-6501, USA; e-mail (MJR): barleymoe@yahoo.com.

THAMNOPHIS ELEGANS (Western Terrestrial Garter Snake) **PREDATION.** On 12 July 2003, at 1330 h, while at Umtanum Creek in southern Kittitas County, Washington, I observed a female *Thamnophis elegans* (585.1 mm SVL, 67.7g) actively foraging along the creek bed. Within several minutes, the snake began to writhe and thrash in the water. I discovered that a large adult crayfish (*Orconectes virilis*) grabbed it with its first pereiopod (chela). Later that day I collected the snake (CWU 1238) after a small portion of skin, associated muscles, and some viscera had been consumed. The length of the crayfish was 135.1 mm TL; no other measurements were taken. Although other species of invertebrates (scorpions, spiders, and centipedes) are predators on snakes (Greene 1994. Biology of the Reptilia, Vol. 16 Ecology B, Defense and Life History, pp. 1–153), I believe this to be the first report of a crayfish capturing and killing a species of snake in the field. In laboratory experiments, Fernandez and Rosen (1996. Effects of the Introduced Crayfish *Orconectes virilis* on Native Aquatic Herpetofauna in Arizona. Arizona Game and Fish Department, Heritage Fund Report IIPAM Project No. I94054, Phoenix, Arizona. 56 pp.) reported that a 60 g crayfish (*O. virilis*) killed and consumed a juvenile *T. elegans* (175 mm SVL, 2.68 g).

I thank D. M. Darda for commenting on this manuscript

Submitted by **ROBERT E. WEAVER**, Department of Biological Sciences, Central Washington University, 400 E. 8th Avenue, Ellensburg Washington 98926-7537, USA; e-mail: weaverr@cwu.edu.

VIPERA ASPIS (Asp Viper). **REPRODUCTION**. Although the reproductive biology of *Vipera aspis* is well described, recent reviews suggest that the form found in Italy represents a distinct lineage, and possibly a separate taxon (Zuffi 2002. Amph. Rept. 23:191–213; Zuffi and Bonnet 1999. Ital. J. Zool. 66:87–95). We captured a female *V. aspis* (588 mm SVL; pre-parturition 330 g; post-parturition 144 g) in Bosco della Fontana (a woodland near Mantua, northern Italy) that gave birth to 17 live neonates on 28 August 2002. Male neonates averaged 196.8 ± 3.8 mm SVL and 6.7 ± 0.5 g (N = 12). Females averaged 200.2 ± 3.0 mm SVL and 6.8 ± 0.2 g (N = 5). This exceeds previously reported litter sizes for Italian populations (Luiselli and Rugiero 1990. Herpetozoa 2:107–115; Luiselli and Zuffi 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 279–284. Eagle Mountain Publishing, Eagle Mountain, Utah; Zuffi et al. 1999. Acta Oecologica 20:633–638). Maximum litter size for French populations of *V. aspis* is 22 neonates born to a female that weighed 375 g pre-parturition and measured 760 mm TL (Naulleau 1976. Ann. Soc. Sc. Nat. Charente Maritime – La Rochelle 6:201–202).

Submitted by **AUGUSTO GENTILLI** (e-mail: augusto.gentilli@unipv.it), **FABIO PUPIN**, and **MAURO FASOLA**, Dipartimento di Biologia Animale, Università di Pavia, Piazza Botta, 9-10, 27100 Pavia, Italy.

Herpetological Review

HERPETOLOGICAL REVIEW

The Quarterly News-Journal of the Society for the Study of Amphibians and Reptiles

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2004 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Department of Biological & Environmental Sciences, Western Connecticut State University, 181 White Street, Danbury, Connecticut 06810, USA. Fax: (203) 837-8769; e-mail: PinouT@wcsu.edu.

Future Annual Meetings

2005 — University of South Florida, Tampa, Florida, 6–11 July (with ASIH, HL)
2006 — New Orleans, Louisiana, 12–17 July (with ASIH, HL)

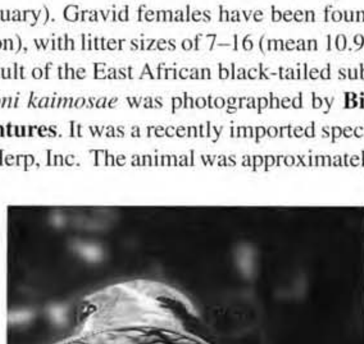
About Our Cover: *Dendroaspis jamesoni*

Mambas (*Dendroaspis*, Elapidae) comprise four species occurring in sub-Saharan Africa. The most notorious of these, the savannah-dwelling Black Mamba (*D. polylepis*), is also the most studied. As a group, mambas possess a powerful venom with strongly neurotoxic properties (Van Aswegen et al. 1996. Wilderness and Environmental Medicine 7:115–121).

Jameson's Green Mamba *(D. jamesoni)* may be the least known. It ranges widely across central African forests to elevations of ~2100 m, from southern Nigeria east to the southern half of Uganda and western Kenya, south to Angola, but also ranges to Togo and Ghana in the northwest, and extends to the Imatong Mountains in the southern part of the Sudan (Spawls and Branch 1995. Dangerous Snakes of Africa. Krieger Publ., Malabar, Florida, 192 pp.).

Although reported to attain a maximum length of 3.66 m (Pitman 1974. A Guide to the Snakes of Uganda, revised edition. Wheldon & Wesley, xxii + 290 pp.), a more reasonable estimate of maximum size is perhaps 2.64 m (Spawls et al. 2002. A Field Guide to the Reptiles of East Africa. Academic Press, San Diego, 543 pp.). In the most detailed field investigation to date of this species, Luiselli et al. (2000. Contributions to Zoology 69[3]:147–155; online at <http://dpc.uba.uva.nl/ctz/vol69/nr03/a01>) studied *D. jamesoni* in southern Nigeria. Their work confirmed this species' strongly arboreal habits and generally secretive, inoffensive behavior. Notably, these snakes are able to persist in patches of remnant forest, often surprisingly near human settlements. Adults are mostly sedentary, favoring retreats in specific trees or bushes, and capture arboreal prey—mainly birds, with some rodents eaten. Juveniles are more likely to consume ectothermic prey such as toads and lizards. Males attain a larger size than females, and male-male combat has been observed during the dry season (December–February). Gravid females have been found during April–June (wet season), with litter sizes of 7–16 (mean 10.9).

The cover image of an adult of the East African black-tailed subspecies *Dendroaspis jamesoni kaimosae* was photographed by **Bill Love / Blue Chameleon Ventures**. It was a recently imported specimen borrowed from Glades Herp, Inc. The animal was approximately 5.5 feet (1.68 m) long and surprisingly (and thankfully) cooperative for the studio session lit by three Novatron lights. A Nikon 60 mm macro lens and F90X body recorded the image on Fujichrome Velvia (ASA 50) slide film. The odd pose was contrived specifically to show most of the snake's color variation along its attenuated body in a vertical close-up format.



SSAR BUSINESS

Seibert Award Winners for 2004 Announced

The thirteenth annual Seibert Awards were presented at the 47th Annual Meeting of the SSAR in Norman, Oklahoma 26–31 May 2004. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meeting, a single award was given in each of the following categories: Systematics (3 eligible presentations), Physiology/Morphology (5 eligible presentations), Evolution (7 eligible presentations), Ecology (8 eligible presentations), and Conservation (11 eligible presentations). All five awardees received a check for US $200 and a book from Chuck Crumly at the University of California Press.

The Winners—Systematics: Adam Leache and Charles Cole, University of California, Berkeley, "Secondary Contact Between Two Putative Species of *Sceloporus* Lizards in Arizona." Physiology/Morphology: Christopher Leary, University of Oklahoma, Norman, "Influence of Individual Physiological Condition on Reproductive Tactic Expression in Toads: Implications for Behavioral Studies." Ecology: Stephen Spear and Charles Peterson, Idaho State University, Pocatello "Spatial Analysis of Tiger Salamanders (*Ambystoma tigrinum*) Gene Flow Across the Northern Range of Yellowstone National Park." Conservation: Nicole Thurgate, University of New Orleans, "Have Canopy Closure and Competition Contributed to the Decline of Endangered Dusky Gopher Frogs (*Rana sevosa*)?" Evolution: Catherine Darst, Pablo Menendez, Luis Coloma, and David Cannatella, University of Texas, Austin, "The Evolution of Toxicity and Diet-Specialization in Poison Frogs: A Comparative Analysis."

Honorable Mention—Ecology: Jason Hoverman, Rick Relyea, and Nancy Schoeppner, University of Pittsburgh, "Direct and Indirect Impacts of Insecticides and Herbicides on Aquatic Communities," Mizuki Takahashi and Matthew Parris, University of Memphis, "Effect of Hydroperiod on Developmental Polymorphisms of the Eastern Spotted Newt, *Notophthalmus viridescens*." Conservation: Carol Strojny and Malcolm Hunter, University of Maine, "A Comparison of Amphibian Abundance in Harvest-Created and Natural Canopy Gaps in a Northeastern Forest." Evolution: Erin Myers, Fred Janzen, and Dean Adams, Iowa State University, Ames, "Quantitative Genetics of Plastron Shape in Slider Turtles (*Trachemys scripta*)."

The judges were Brian Crother (Southeastern Louisiana University), David Bickford (University of Texas, Austin), Robert Espinoza (California State University, Northridge), Stanley Fox (Oklahoma State University, Stillwater), David Hardy, Sr. (Tucson, AZ), Joe Mendelson, III (Utah State University, Logan), Meredith Mahoney (UC Berkeley), Kirsten Nicholson (Washington University), Marion Preest (The Claremont Colleges), and Paul Stone (University of Central Oklahoma).

SSAR Grants-in-Herpetology Committee Annual Report (2004)

An award in the amount of US $500 was made to each of the following individuals:

Field Research.—**Steven M. Whitfield**, Florida International University. Project title: "Costs and benefits of male versus female parental investment in *Eleutherodactylus johnstonei*, a frog with amphisexual parental behavior."

International.—**Franklin Enrique Castañeda Menéndez**, Universidad de Costa Rica. Project title: "Movement, activity pattern and habitat use of *Kinosternon scorpioides* (Testudines: Kinosternidae), in a dry tropical forest in Costa Rica."

Conservation.—**Corinne L. Richards**, University of Michigan. Project title: "Elucidating factors integral to the conservation of endangered Panamanian Golden Frogs (*Atelopus varius* and *Atelopus zeteki*)."

Laboratory Research.—**Melissa A. Pilgrim**, University of Arkansas. Project title: "Assessing the impact of diet composition on Pygmy Rattlesnake (*Sisturus miliarius*) life history and demography: a stable isotope approach."

Travel.—**Mizuki Takahashi**, University of Memphis. Project title: "Phylogeography and population differentiation of the Eastern Newt, *Notophthalmus viridescens*."

2004 Grants-in-Herpetology Committee.—Chair: Erik R. Wild. Reviewers: Jeffrey Parmelee, Karen Lips, Daniel Meinhardt, David Kizirian, Christopher Beachy.

SSAR congratulates the 2004 GIH recipients and thanks the committee members for their efforts.

Grants-in-Herpetology 2005 Proposals

Proposals are now being accepted for the 2005 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Application deadline is 31 December 2005. Grant application details are available at:

<http://www.ssarherps.org/pages/GIH.html>

SSAR Special Award in Herpetology at the New Haven City Wide Science Fair

In an effort to promote herpetological education among children in grades K–12, the SSAR Board of Directors agreed to support a Special Award in Herpetology for the 2004 New Haven (Connecticut) City Wide Science Fair. The New Haven Science Fair is an important part of the City's K–12 science program because the New Haven science curriculum requires every school in the district to enter projects. Many of these go on to compete on the state level (www.nhsciencefair.org/html/home.html).

The winner of the SSAR 2004 Special Award in Herpetology is fifth grader Adam Hallet, from Sheridan Middle School. Adam exposed lizards to different colored light (white, red, blue, and green) and measured their respiratory response. He found that they consistently breathed slowest under green light and fastest under white light. Adam used the change in the rate of rhythmic expanding and contracting of the rib cage to measure breathing rate. Although he wasn't sure why colored light affected rates of breathing he did remember reading about the pineal organ and felt that it might somehow be involved in controlling lizard respiration.

Adam Hallet in front of his project poster and trophy.

In interviewing Adam I learned that he loves lizards and reads about them all the time. He told me he developed his project alone after trying to decide how to best calm his pet Forest Armadillo Lizards in their cage. Now that he has completed this Science Fair project he wants to examine skulls of different lizard species. When asked where he was going to get these skulls he replied in a very matter of fact manner that "everyone knows that drawings of skulls are published in the literature."

On behalf of the Society for the Study of Amphibians and Reptiles and its Board of Directors I would like to extend our warmest congratulations to Adam, his family, and his science teacher Huan Ngo, and wish Adam all the best in his future scientific inquiries. I would also like to thank SSAR member Gregory J. Watkins-Colwell of the Peabody Museum of Natural History, who kindly agreed to judge the award.

Anyone serving on a local Science Fair Board who would like to facilitate this type of award should contact the SSAR Treasurer at theodora.pinou@yale.edu for more information.

—*Theodora Pinou, SSAR Treasurer*

NEWSNOTES

Biology of Sea Snakes Workshop: The Nha Trang Declaration

A workshop on the Biology of Sea Snakes (elapids with a flat paddle-like tail), was held at the Institute of Oceanography, Nha Trang, Vietnam, 9–12 March 2004, jointly organized by the DANIDA Research Council, the Royal Danish Academy of Fine Arts, School of Conservation, and the Institute of Oceanography, Nha Trang. The following scientists, representing eight countries, participated: Touch Seang Tana (Cambodia); Jesper Norup Nielsen, Peter Gravlund, Jens Boedtker Rasmussen, Arne Redsted Rasmussen (Denmark); Medy Ompi (Indonesia); Indraneil Das (Malaysia); Filipina B. Sotto (Philippines); Anslem de Silva (Sri Lanka); Somchai Bussarawit, Lawan Chanhome, Visith Sitprija, Sansareeya Wangkulangkul (Thailand); Chu Anh Khanh, Nguyen Thi My Ngan, Cao Van Nguyen (Vietnam).

The following resolution—the Nha Trang Declaration—was adopted:

1) Sea snakes contribute significantly to the biological diversity of marine, coastal and freshwater ecosystems of the Indo-Pacific region.
2) The natural habitats of sea snakes are rapidly being degraded through pollution, use by humans and their impact, and thus require immediate assessment. Appropriate management options may need to be adopted in order to stem the decline of sea snake populations as a result of habitat destruction.
3) Intensive fishing activities, especially the use of trawlers, result in the incidental capture of a large number of sea snakes, a large proportion of which perish. This is a senseless loss of a valuable biological resource, the ecological implications of which are not well understood at present.
4) Systematic knowledge of the group, in addition to knowledge of biology and conservation status, remains poor.
5) For effective species conservation, more research is needed on these and other aspects of the natural history of sea snakes and of their habitat requirements.
6) Efforts to enhance conservation of sea snakes should include: Institutional capacity building, training, especially of students, husbandry, development of databases on trade, and other forms of use, bites, a general exchange of information between sea snake workers and others interested in their management and conservation, a review of legislation, and finally a public awareness programme.
7) Many fishermen and some tourists get bitten by sea snakes every year throughout the region. A number of these bites result in death. Thus, the status of bites by sea snakes and preventive methods need to be ascertained.
8) Where bites from sea snakes are a problem, specific anti-venom needs to be developed where it is not currently available.
9) Sea snakes are a shared common resource. The migratory habits and wide distribution of some species make them ideal candidates for regional cooperation in studies of biology and conservation. Such cooperation between institutions and individuals, representing many countries of the Indo-Pacific region, has been ongoing for the past decade. These collaborative ventures need to be carried on in the future.

—*Arne Redsted Rasmussen (e-mail: arr@kons.dk)*

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

15–20 November 2004—VI Symposium of Zoology, Topes de Collantes, Sancti Spiritus, Cuba. Information: www.geocities.com/zoologiacubana/simposio or by e-mail: zoologia.ies@ama.cu.

16–18 January 2005—Biology of the Rattlesnakes conference, Loma Linda, California, USA. Information: www.BiologyoftheRattlesnakes.org.

OBITUARIES

Herpetological Review, 2004, 35(3), 211–212.

C. Robert Shoop (1935–2003)

C. KENNETH DODD, JR.
USGS/Florida Integrated Science Centers
7920 NW 71st Street, Gainesville, Florida 32653, USA
e-mail: ken_dodd@usgs.gov

Bob Shoop (often affectionately known simply as "Shoop") was born in Cicero, Illinois in 1935. He attended Southern Illinois University for his Bachelor's degree (1957), then migrated south to Tulane University for his Master's (1959) and Doctoral degrees (1963). At Tulane, two important events helped shaped Bob's life: he studied the biology of *Ambystoma* and *Necturus* under Fred Cagle, and he developed a connoisseur's appreciation for barbeque, a taste which came in handy during later years of preparing mystery meat dinners for friends and visitors at the University of Rhode Island and on Cumberland Island. After graduating, he briefly worked at Oak Ridge before taking a position at Wellesley College, where he taught for 7 years. Wellesley had no graduate program, so in 1969 he accepted a position in the Zoology Department at URI where he remained until his retirement in 1998.

By all accounts, Bob was an enthusiastic teacher as he instilled an excitement and curiosity about the natural world in serious Yankee students. His zeal and sense of humor punctuated long winters of teaching undergraduate and graduate courses. At URI, he led numerous "road trips" to the southeast to expand the horizons of his students and to show them the diverse world of amphibians and reptiles. Bob served as major professor to 8 Doctoral students and 18 Master's students who worked on a wide variety of research projects, although most had herpetological interests. In addition, he served as committee member to nearly 50 additional graduate students, all at URI. The warm remembrances from colleagues, students, and friends at the university present a picture of the man many of us were privileged to know: knowledgeable; warm and friendly; possessed of a great love of life and sense of humor, even among those with whom he disagreed or in adverse situations.

He never stopped being a teacher, either to students or to colleagues. For example, Bob was vexed by sea turtle measurements, and expressed concern about their accuracy and the growth claims made by some researchers based on mark-recapture measurements. At one Sea Turtle Workshop, he brought a loggerhead carapace to the meeting and placed it near the registration desk with a set of calipers and a measuring tape (but no other instructions) and a sign: "Measure this Turtle." As he predicted, the variance in the measurements exceeded anything that could possibly be meaningful, even though taken by experienced researchers using "standardized" techniques on a stationary carapace. I later adopted this exercise on occasion to illustrate the potential for observer bias in taking measurements.

During his career, Bob published more than 65 papers, most of them dealing with the ecology and life history of amphibians and reptiles. Although his dissertation focused on *Necturus*, he quickly became interested in the orientation, migration, movement patterns, and survivorship of *Ambystoma* salamanders, publishing some of the earliest and most important papers on these topics. In fitting tribute, a plaque in his honor will be placed at the URI Alton Jones Research Center, where he did much of his amphibian work. In the late 1970's, Bob's interests shifted to marine turtles, a passion he pursued until his death. Indeed, he had just finished a revision of his *Sea Turtles of the Georgia Coast* with Carol Ruckdeschel shortly before the stroke that ended his life. And although salamanders and sea turtles came to dominate his publication list, Bob was keenly interested in everything concerning the natural world. This is particularly true of Cumberland Island, Georgia, a place he often visited and retired to in 1998. Shoop never really retired, he just had more time to work on turtles and the biology of Cumberland Island (29 papers beginning in 1982).

While at Cumberland, Bob became increasingly concerned about the conservation of marine turtles in offshore waters. He was fiercely dedicated to finding a solution to the problem of "incidental" mortality due to shrimp trawling and other commercial fishing, and he was not afraid to challenge authority, especially when he had the data to show that half-way technology and agency-espoused "solutions" simply were not effective. I remember many discussions with him and Carol, where they convincingly argued that the regulations imposed did not address the root cause of the sea turtle strandings. Bob was not fond of bureaucratic intransigence.

On Cumberland Island, Bob lived out his dream with Carol Ruckdeschel at their home at The Settlement; he especially loved his mule and taking buggy rides in an Amish carriage. Bob was a pilot, a writer for *Special Edition of The Mullet Wrapper*, a recipient of the ASIH Stoye Award (1960), Vice President of the Cumberland Island Museum (1985–2003), auctioneer at sea turtle meetings, teacher, researcher, conservationist, chef, mentor, and distinguished naturalist. I will very much miss our talks of turtles, wine, herpetology books, food, and southeastern life. Bob is survived by his life-mate, Carol, his sons John and Michael, 3 grandchildren (Cassandra, Jack, Alexis), a brother (Steven), and a whole lot of friends. Memorial celebrations of his life were held at Cumberland Island and the University of Rhode Island.

Herpetological Review, 2004, 35(3), 212–213.

Richard L. Wallace (1933–2003)

LOWELL V. DILLER
Simpson Resource Company, P.O. Box 68
Korbel, California 95550, USA
e-mail: ldiller@simpson.com

Richard ("Dick") L. Wallace, 70, Professor Emeritus of Zoology, University of Idaho, died on November 13, 2003 in Moscow, Idaho. He had a long and productive career and made important contributions to the fields of ichthyology and herpetology, but to his former colleagues, graduate students and friends, his greatest contribution was the friendships they shared. Working in an academic world where self-promotion is common, he was direct, completely unpretentious, sought no recognition for himself and was willing to devote long hours assisting his graduate students and colleagues. As one former graduate student said: "They don't make'em like him anymore. I consider myself very lucky to have known him … I would have never finished my Master's thesis if it weren't for Dick's guidance and expertise." Another former graduate student remarked, "Dick didn't just adopt me, but my entire family as well. He was concerned with our welfare in addition to my progress as a scientist. He was one of the most generous people I've known in academia."

I know I can never capture the essence of a man for whom I had

such love and respect, but my personal testament to his special qualities is all the years he supported our field studies on rattlesnakes out of his personal income. We were unable to get more than small grants to conduct our fieldwork, but his interest in nature and devotion to science did not allow this to deter our work. Largely through his personal support, we continued the work from 1978–1990. As he would be the first to say, the studies on rattlesnakes may not have been "profound," but they were done with a genuine and pure interest in science that is not always evident in today's scientific studies. We conducted fieldwork mostly on weekends during the spring and summer, and in the winter we would use the weekends to catch up on laboratory work and data analysis. Although Dick had a deep love and respect for the animals he studied, he was definitely from the old school that believed in the scientific value of "sackin' up" some specimens. One of my favorite memories was our tradition of going to the lab on Saturdays to do dissections. The work was tedious, but allowed for hours of lively, mostly scientific discussions, with coffee and a donut for our snack. Dick would be dissecting a rattlesnake with all manner of unmentionable "uck-puck" (his favorite term) on his fingers, and if he needed to record something on the data form or took a bite of his donut, he simply licked his fingers and proceeded. He agreed with my admonishments that he probably shouldn't do that, but in a short time, he was right back to using the most natural of cleaning methods. Another memorable occasion was one Saturday when we were dissecting some gravid female rattlesnakes and Dick kept insisting that the mature ova looked "real tasty." We must have forgotten the donuts that day, because we decided that science would be no worse off if we cooked up a couple of the ova. It probably is no surprise that they were terrible and we were never tempted to eat any of our specimens again.

Dick was born August 22, 1933 in Tacoma, Washington and grew up in the same town. He earned his Bachelor of Science degree in conservation from Washington State College in 1956. Following two years in the U.S. Army Signal Corps, he began graduate studies in fisheries science at Oregon State College in 1958 where he received Master of Science and Doctoral degrees in 1960 and 1969. He began his academic career in 1960 at Oregon State University and accepted a position as acting Assistant Professor of Zoology at the University of Idaho in September 1967. At the University of Idaho, Dick taught ichthyology, general zoology, herpetology and biological science courses. He was tenured in 1972 and was promoted to Professor of Zoology in 1984. During his academic career at the University of Idaho, he had graduate students in both fisheries science and herpetology. He retired from the University of Idaho in 1991.

Dick's professional memberships included the American Fisheries Society, American Society of Ichthyologists and Herpetologists, Society for the Study of Amphibians and Reptiles, The Herpetologists' League, Idaho Chapter American Fisheries Society, Oregon Chapter American Fisheries Society (charter member), Pacific Fishery Biologists, Sigma Xi, Phi Sigma and Phi Kappa Phi. During his career, he authored or contributed to four books, and over 60 refereed publications and papers. One of Dick's most notable publications was the *Fishes of Idaho*, which he co-authored with James Simpson in 1978. This text was the first that described Idaho fish species, their biology and distribution.

After retiring, Dick stayed active pursuing his life-long passion for fishing and hunting, but he also did consulting work that included both fish and amphibian studies. Most of the herpetological work was done for Simpson Timber Company in northern California, where true to his style, he insisted that he work for only modest compensation. However, his efforts were instrumental in developing a research and monitoring program for forest amphibians that may well set the standard for the forest products industry. Upon his death, Dick was working on a field guide to the native fishes of Idaho, and the morphological variation and distribution of Idaho sculpins. He is survived by his wife Margaret, son John Wallace, daughters Kate Mecham and Liz Branter, and grandchildren Meredith Wallace, Megan Mecham, and Zachary and Nicholas Branter.

For many of us that knew him during his active post-retirement years, he was simply "Wallace," and on any gathering with two or more of his friends, a favorite pastime was telling Wallace stories. One of my favorites was related to his life-long nemesis, elk. On a particularly cold elk hunting expedition, he got a late start hunting in the morning, and was once again unsuccessful, because he had put his dentures in a glass of water before going to bed and awoke to have them frozen solid in a block of ice. He delighted in telling fishing and hunting stories, but in keeping with his self-deprecating style, he was just as likely to tell you about his "screw ups" as his successes, of which he had plenty. Although he commonly told these stories in greater detail than anyone needed to know, his obvious enjoyment and passion for being in the outdoors made every story worth the wait. We have truly lost a great champion of science, and to all those that knew him, a great friend. We can only hope that he is now where the trout and white-tailed bucks are big and on the move.

e-mail: jbmurphy2@juno.com

John E. Werler was born on 11 June 1922 in Oldenburg, Germany, and immigrated to Weehawken, New Jersey in 1926. He "cut his teeth" in herpetology and the zoo field in Staten Island, New York City. His father was not pleased with his nascent interest in natural history so he burned his animal books. His recollections: "During my early teens I developed a keen interest in reptiles, a passion that inevitably led me to Staten Island Zoo's reptile study society." The group's monthly meetings were held at the Staten Island Zoo, which maintained one of the nation's premier reptile collections. Carl Kauffeld, the zoo's charismatic reptile curator, usually conducted the meetings. According to John, "it was an opportunity to mingle with others, both amateur and professional, who shared the same interest."

From Weehawken it was a tedious journey by bus and ferry to Manhattan, trudging several blocks to a subway station, then on to another ferry terminal for Staten Island, a long ferry ride and then yet another bus to the zoo.

However, John did not mind the two-and-a-half hour one-way trip because "for the next couple of hours I would share a common passion with others," and "to a budding young herpetologist, this was the ultimate experience." "Becoming a member of the Staten Island Zoo reptile study society was one of the most important events of my young life," he reminisced decades later. A year after he had joined the group, a keeper position became available and he applied. Fortunately for him and the herpetological world, Carol Striker, the zoo director, sent him a memo, dated 18 October 1940: "This letter will serve to notify you that you have been appointed to the position of Reptile Keeper, Second Class, salary \$1200.00 per year, effective October 1st, 1940." Thus John Werler, at the age of eighteen, began a productive and successful zoo career, which spanned half a century until his retirement as the Houston Zoo director in 1992.

His new boss, the legendary Carl Kauffeld, continued to be a willing mentor. "It was not unusual for him to spend an hour or two explaining to a keeper or a curious novice the basics of taxonomy, the secrets of captive reptile maintenance, or the historical background of herpetology." John's duties ranged far beyond the maintenance of exhibits and caring for reptiles. Ahead of his time, Kauffeld was aware of the need for accurate record keeping on each specimen under his care. Application of computer chips on live animals was but science fiction then; the task required manual markings on animals as a permanent identification. John's job was to assist the curator with individually marking rattlesnakes. And the zoo had a large number of rattlesnakes.

"It involved pinning each snake to the floor with a snake stick, then grasping the reptile behind the head with the other hand," John noted. He was to hand-hold each specimen while Kauffeld clipped certain scales under the snake's tail. "Picking up the first two snakes went according to plan; the third did not. It jerked its body backward violently just as the snake stick was being lifted

John E. Werler, then-curator at the San Antonio Zoo, and rattlesnake friend. A variation of this photograph was used on the cover of his bulletin on the venomous snakes of Texas. Photo courtesy of John E. Werler.

from its head. When the sudden, unexpected snap loosened my hold, the rattler instantly turned its head to one side, sinking one of its fangs deep into my right thumb. The bite was serious enough to keep me in a local hospital for five days, and in ten days I was back at the zoo. In spite of the accident I was able to perform my usual routine duties upon my return."

"But I faced a nagging question: would I be mentally prepared to once again pick up and hand-hold a venomous snake?" The painful experience was fresh in the young man's mind as he confronted a momentary, paralyzing doubt. However, "I was determined not to let that fear destroy my confidence."

After returning to work, one day he used a snake stick to pull a large cottonmouth from its cage, placing it on the service aisle floor before him. "Almost reluctantly—remembering vividly the circumstances of my first snake bite—I pinned the reptile's head with the stick. But for a brief attempt to pull itself free from the restraining device, the snake remained calm as I picked it up. When it was over, there was perspiration on my forehead, but the deed was done, the challenge met, and my confidence regained. I was back in the business of reptile keeping." [The foregoing is from a four-page note he sent to KK, dated 10 June 1999]

In 1946 John became curator of reptiles at the San Antonio Zoo and was promoted to assistant director in 1952. He moved to the Houston Zoo and served as general curator from 1954 to 1963, when he became the director. As part of the ceremonial opening of the zoo's Reptile House in 1964, Werler demonstrated proper handling of a cobra. He majored in biology at William & Mary College and served four years in the U. S. Coast Guard.

Following the turbulent 1960s, the American zoo world faced formidable challenges in the next decade. The precarious financial status of municipalities caused difficulty for many urban zoos. Moreover in the era of awakening environmental awareness, zoos became a target of criticism from increasingly vocal animal advocate groups. As federal laws, regulations and an international treaty on wild animal trade became stricter, wholesale importation of wild animals was coming to a screeching halt. Soon, it became vitally important for zoos to maintain self-sustaining populations by effectively managing captive wild animals in a more scientific manner.

As the Houston Zoo director, John Werler hosted the 1973 annual conference of the American Association of Zoological Parks and Aquariums (AAZPA, now American Zoo and Aquarium Association, or AZA). It was an unusual conference with a heavy dose of technical paper sessions on breeding and small population management of zoo animals. It was at this conference that the future direction for zoo animal management was laid out, based on biological principles, especially genetics. Later, the National Academy of Sciences (1975) published the conference proceedings.

One of the critical animal management issues surfacing in the forefront of the AAZPA was that of surplus animals. While some species were not reproducing sufficiently, on the other hand offspring of certain species were "flooding" the market, causing a serious dilemma for zoos. Contemplating the issue John alerted his colleagues eloquently (1974): "We are well aware that a major factor in the reduction of wildlife is vanishing habitat. A related problem, unique to our profession, is becoming increasingly evident — that of vanishing space. We have become extremely suc-

cessful in breeding certain species." He continued, "Even when occasional rare species are successfully bred in captivity, there remains the nagging problems of finding space to properly accommodate the expanding captive groups." Ahead of his time, he then suggested a need for a collective animal management program. As zoos faced more rapid changes, John Werler took the AAZPA presidency for the period 1975 to 1976 and made every effort to resolve difficult issues. [He told KK around that time that after he had made a critical decision, a prominent Texas zoo director did not speak to him for a year.]

Houston Zoo director John E. Werler (right) with reptile curator Tommy Logan during the mid-1960s. Photo courtesy of John E. Werler.

Gary K. Clarke, retired director of the Topeka Zoo, Kansas and a former AAZPA president (1971–1972) comments (pers. comm.): "John was one of the all-round zoo professionals who emerged from initial interest in herpetology." Speaking of herpetology, Chris Wemmer of the Smithsonian National Zoological Park wondered (1991), "How come herpetologists tend to be more committed biologists than bird and mammal curators?" He also observed, "Their intellectual commitment is manifested by higher individual publication rates, more collaboration with non-zoo biologists, more field experience, and probably higher per capita membership in professional societies." John Werler typifies this particular breed of zoo professional. Dr. Wemmer then revealed a list of 21 scholars worldwide in "A Gallery of Zoo Researchers and Zoo Biologists." Included in this impressive roster were highly respected European scholars, along with John Werler and his mentor Carl Kauffeld.

In Werler's honor, Roger Conant described the Tabasco Watersnake *Natrix* (= *Nerodia*) *rhombifera werleri* in 1953. Two amphibians from Veracruz, Mexico were named after Werler: Werler's False Brook Salamander (*Pseudoeurycea werleri*) and the leptodactylid frog *Eleutherodactylus werleri* [now *E. laticeps*]. Later this year, a paper by Jonathan Campbell and Werler will appear in *Southwestern Naturalist* describing a new species of lizard (*Diploglossus* sp.) named after Werler's beloved late wife.

Werler died of cancer on 21 March 2004. He and his wife Ingrid had one son, John H. Werler.

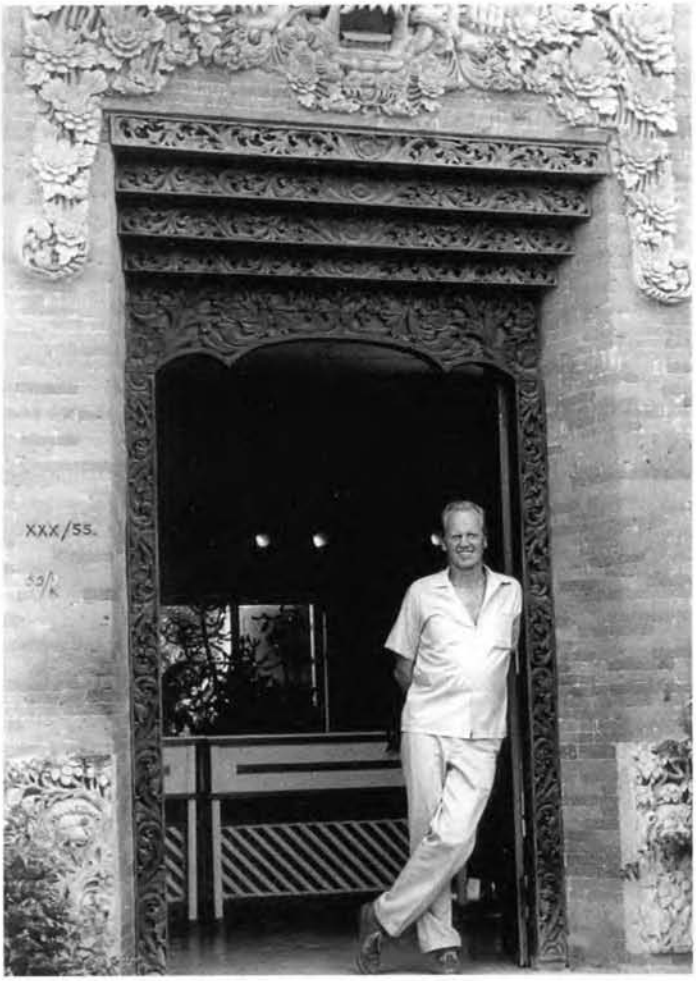
Walter Auffenberg (1928–2004)

RICHARD FRANZ
Florida Museum of Natural History, P.O. Box 117800
University of Florida, Gainesville, Florida 32611-7800, USA
e-mail: dfranz@flmnh.ufl.edu

Walt Auffenberg passed away on 17 January 2004 at the age of 75 after a long illness following a stroke in December 1995. He is survived by two sons, Kurt and Troy, six grandchildren, and two great-grandchildren. Walt was born in Detroit, Michigan, on 6 February 1928, the only child of Walter and Ida Auffenberg. He developed a passion for herpetology early in his childhood, and by the time he graduated from Denby High School Walt had amassed a sizable collection of preserved snakes. If he made good grades in school, Walt was allowed to take the bus or hitchhike to far off places, such as Florida and Mexico, to collect herps. His parents had purchased two small orange groves and a fernery near Deland, Florida, for their eventual retirement, and after graduation from high school, Walt tended these small plots of land. Walt enlisted in the Medical Corps of the United States Navy near the end of World



Walter Auffenberg, December 1969, Arya Hotel, Denpasar, Bali, Indonesia, about midway through his field study of the Komodo Monitor.

War II and was stationed in Corpus Christi, Texas. When not playing piano for the officers' entertainment, he would travel to Houston to play where he eventually met and in 1947 married Elinor Ann Wright. The Auffenbergs would have four sons (two deceased) and share a very special relationship over the next 45 years until Elinor's death in 1992. Walt married Katalin Vienne in 1993, but she too passed away in 1999.

In the late 1940s, Walt found employment as a draftsman for Sinclair Oil Company in Houston. However, his supervisor at the time urged him to follow his dream of becoming a herpetologist. So, Elinor and Walt (and one son) moved to Deland, Florida, where he attended Stetson University on the G.I. Bill. He received his B.S. in 1951. The family moved to Gainesville so Walt could pursue his graduate studies in the Department of Biology at the University of Florida. He received his master's degree in 1953. Prior to finishing his Ph.D., Walt took a job as Associate Curator of Vertebrate Paleontology at The Charleston Museum during 1954–1955, and then moved to Harvard University in Fall 1955 to become a student assistant with Ernest Williams. Walt finished his doctoral degree at the University of Florida under the direction of Arnold Grobman in 1956. His dissertation on the fossil snakes of Florida became a benchmark study for all later studies in snake paleontology. Grobman recruited Walt to become Associate Director of the Biological Sciences Curriculum Study (BSCS) program at the University of Colorado at Boulder in 1959. There, Walt helped guide the development of the green, yellow, and blue versions of the innovative high school biology texts that provided many of us with our initial exposure to biological principles. It was during this time that Walt first traveled to Asia where he promoted the BSCS program and taught in India. Following Grobman's departure from BSCS, Walt returned to the Florida State Museum (now Florida Museum of Natural History) in 1963 as Chairman of Natural Sciences and Curator of Herpetology. This allowed Walt to continue his research on fossil and living amphibians and reptiles and raise his family in Florida. Walt stepped away from his Chairman responsibilities in 1973 to devote full attention to his duties in Herpetology until his retirement in 1991. During his 27-year career at the University of Florida, he was the graduate advisor of Dave Auth, John Iverson, Dale Jackson, Peter Meylan, Bob Taylor, and Bill Weaver, guiding them through their doctoral programs and inspiring numerous master's students.

Walt published more than 130 scientific papers and books on fossil amphibians and reptiles, the musculature of snakes, recent and fossil tortoises, and the systematics, evolution, and ecology of reptiles. His foray into the ecology and behavior of the varanid (monitor) lizards began in 1968 when F. Wayne King, then of the New York Zoological Society, recruited him to take on a project that would change his life forever. Along with Elinor and his three youngest children, Walt journeyed to the island of Komodo where he and his family lived for 11 months (1969–1970) to study dragons. This culminated in his landmark book on this species published in 1981. Two more books followed to complete his famous trilogy on varanid lizards. Walt received the Wildlife Society's Best Wildlife Book Award for his Komodo dragon book. Walt also investigated the ecology and conservation of gopher tortoises and West Indian rock iguanas. He inspired the formation of the Gopher Tortoise Council in 1978, a sister organization to the Desert Tortoise Council, both of which continue today as important advocates for the conservation of these turtles. At the time of his stroke, Walt was involved in a major study on the amphibians and reptiles of Pakistan, which his son, Kurt, and numerous colleagues around the world plan to complete. Walt lamented numerous times during his prolonged illness that he would never be able to conduct his dream study on the ecology and behavior of the Bornean lizard *Lanthanotus*.

Walt was much more than a great herpetologist, paleontologist, teacher, and family man. He was a remarkable pianist, guitar player, motorcyclist, and roller skater. He was also a fabulous artist, producing virtually all of the scientific illustrations used in his publications. Walt Auffenberg was a dynamic teacher, mentor, colleague, and friend to me. He will be missed.

Editor's note.—A complete list of Walter Auffenberg's publications can be found at:

http://www.flmnh.ufl.edu/natsci/herpetology/uf-herp/alumni/Auffenbergbiblio.htm#auffenbergbiblio

Herpetological Review, 2004, 35(3), 217.

Sherm Ketcham (1926–2004)

DAN MILLER
Bramble Park Zoo, 800 10th Street NW
Watertown, South Dakota 57201, USA
e-mail: dmiller@watertownsd.com

Family and friends are deeply grieved by the passing and loss of friend, mentor, and associate Sherm Ketcham, who passed away on 1 February 2004. He had been battling cancer for years and died peacefully. He was 78.

He will be remembered for his passion for conservation and education, his interest in herpetology, and many contributions to the zoo profession through his work at the Detroit Zoological Park (now Detroit Zoological Institute) and Milwaukee County Zoological Gardens.

His childhood love of animals led him to a lead zookeeper position at the Detroit Zoological Park after serving in WWII and the Korean War. Sherm worked there from 1961 to 1970 and was promoted to supervisor of reptiles. He was instrumental in the opening of Holden Museum of Living Reptiles.

From 1970 to 1983, Sherm was employed as Curator of Reptiles at the Milwaukee County Zoo. He developed many of the naturalistic reptile exhibits, improved husbandry techniques and bred many reptiles, especially pythons. Throughout his career, Sherm held firmly to the idea that everyone should have the opportunity to view reptiles up close and in naturalistic exhibits. He designed many exhibits that were innovative and state of the art for the time. Sherm's reptile handling ability is still considered extraordinary by some. Sherm was instrumental in developing "Animal in Action," a hands-on educational program in which zookeepers presented reptile talks to zoo visitors. He also implemented public feeding of snakes so that zoo visitors had the opportunity to view these interesting feeding behaviors.

Sherm was quite the reptile collector, and spent a considerable amount of time in the field collecting and observing reptiles. He was one of the first to utilize early radio telemetry in tropical snakes in Peru and Costa Rica. Sherm assisted with many reptile field projects and is mentioned in numerous reptile publications.

Perhaps his greatest contribution to herpetology was his devotion to educating, training, and motivating young people interested in working with reptiles, a task he accomplished with great ease. During his free time, Sherm presented reptile talks to nursing homes and scouts groups, as well as other organizations. He possessed a contagious enthusiasm that inspired so many around him to excel and achieve, and it is in this capacity as a mentor to aspiring herpetologists that he will be missed the most.

Those wishing to express their appreciation for Sherm Ketcham and his work may direct memorial contributions to Marje Ketcham at 57 Midway Rd, Eldon, Missouri 65026, USA. Contributions will be used for a memorial at the Detroit Zoological Institute.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **María del Rosario Castañeda**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

12S and 16S Mitochondrial Genes in Frog Systematics

Although fragments of the 12S and 16S mitochondrial genes have been used extensively in studies of amphibian phylogenies, the usefulness of these genes at different hierarchical levels has not been examined in detail. The authors sequenced 400-bp segments of 12S and 500-bp segments of 16S in Discoglossidae (to examine recent splitting events) and several archaeobatrachians (to examine basal splitting events); additional sequences of other amphibian and reptile taxa were obtained from GenBank. Phylogenetic trees were constructed with maximum parsimony (PAUP 4.0b8), maximum likelihood (Tree-Puzzle 5.0), Bayesian analysis (Mr Bayes 2.01), and one-step analyses (POY). Results indicated that secondary structure of rRNA is not fixed in taxa with highly divergent primary sequences. Moreover, different alignment methods (e.g., POY, CLUSTAL X) resulted in disparate hypotheses of positional homology, number of variable characters, and number of parsimony-informative characters. In all analyses, recent splitting events received universal support, whereas conflicting hypotheses were identified regarding the major anuran clades. The authors suggest noise in the data and uncertain primary homology statements produced conflicting results, and 12S and 16S ribosomal genes should be used with considerable caution to infer the "early phylogeny" of frogs.

HERTWIG, S., R. O. DE SÁ, AND A. HAAS. 2004. Phylogenetic signal and the utility of 12S and 16S mtDNA in frog phylogeny. Journal of Zoological Systematics and Evolutionary Research 42:2–18.

Ambush Strategies of *Crotalus horridus*

To be effective ambush predators, vipers use chemoreceptive

stimuli to identify ambush sites near suitable prey. Clark tested the behavioral reactions of 24 juvenile *Crotalus horridus* to tap water (control) and aqueous extracts of the integument of a frog, a lizard, and six species of mammals. Snakes directed most tongue flicks toward integuments from white-footed mice and chipmunks; stereotypical ambush posture was initiated by snakes most often when these prey-item scents were encountered. Snakes directed the fewest tongue flicks toward scents from animals that are either allopatric with the Pennsylvanian population of tested snakes, or species that are not usually preyed upon by *Crotalus horridus* (e.g., dogs). The results of this study complement previous studies that documented a link between prey scent and snake ambush strategies.

Vocal Communication in *Xenopus laevis*

Anuran calls have been associated with reproduction and intrasexual communication in many species. The authors examined the effects of gender and gonadotropin injections on calling behavior of *Xenopus laevis* in captivity. Field recordings of wild animals were made near Cape Town, South Africa for comparison. Analysis of field recordings identified eight call types, including one call (chirping) that had not been described in previous studies. In lab experiments, males vocalized to both sexes, but females vocalized only to males. Male-male interactions involved more calls and clasping when one or both of the males were injected with gonadotropin; dominance in clasping behavior was closely associated with dominance in calling. The authors suggest *X. laevis* establishes a vocal hierarchy in which dominant males emit advertisement calls, and vocally suppressed males (subordinates) rarely advertise.

A Molecular Phylogeny of *Bolitoglossa*

The Neotropical salamander genus *Bolitoglossa* includes more than 80 species from a diversity of habitats between Mexico and central Bolivia. The authors conducted a phylogenetic analysis on numerous species of *Bolitoglossa* to address hypotheses regarding multiple colonization of tropical lowlands and the invasion of South America. Data used for this study included 1196 bp of 16S and cyt *b* genes from 55 species (including 7 unnamed taxa); outgroups included *Batrachoseps, Thorius,* and *Pseudoeurycea.* Phylogenetic analyses included maximum parsimony, maximum likelihood, and Bayesian analysis. Results supported a monophyletic *Bolitoglossa* and seven clades that are consistent with previously recognized groups within the genus. Taxonomic implications of the results are discussed in detail. The authors suggest members of one clade (*Eladinea*) invaded South America before the establishment of the Isthmian link.

PARRA-OLEA, G., M. GARCÍA-PARÍS, AND D. B. WAKE. 2004. Molecular diversification of salamanders of the tropical American genus *Bolitoglossa* (Caudata: Plethodontidae) and its evolutionary and biogeographical implications. Biological Journal of the Linnean Society 81:325–346.

Intraspecific Communication with Chemical Cues in *Leiopelma*

Although bioacoustic communication is widespread among frogs, the earliest anurans probably never evolved this ability. *Leiopelma hamiltoni* belongs to an ancient lineage of frogs dating back to the Jurassic. This species has many morphological and behavioral similarities to salamanders, including well-developed vomeronasal and olfactory senses. The authors tested the ability of *L. hamiltoni* to communicate with chemosignals in captivity. Sixty wild-caught frogs were placed in plastic boxes with two paper towels (one on each side) containing either no scent or conspecific integumentary scents. Movements of test subjects toward either side of boxes were recorded. Results indicated strong preference for a given test subject's own scent to an unscented paper towel or a conspecific's scent if the conspecific was collected more than 5 meters away from the test subject (i.e., unfamiliar individual) in the wild. When limited to a choice between an unscented paper towel and one marked by an unfamiliar conspecific, test subjects spent more time near the unscented paper towel. This is the first study to demonstrate that adult anurans use chemical cues for intraspecific communication.

A Molecular Phylogeny of *Iberolacerta*

To identify "meaningful conservation units" and explore the history of the genus *Iberolacerta,* the authors sequenced a 460 bp segment of the control region and right domain region, and a 1033 bp segment of cytochrome *b*. Distances between haplotypes were computed in MEGA, and trees were constructed using maximum parsimony (MP) and maximum likelihood (ML) in PAUP*. Divergence-time estimates were obtained from previous substitution rates for reptilian cytochrome *b*. Both methods of tree construction produced four well-supported clades within the monophyletic genus, but the MP and ML trees differed in the position of some taxa. The authors suggest isolation of the four main clades occurred in the northwestern Iberian mountains, the Central Ibe-

rian mountains, the Pyrenees, and the eastern Alps. *Iberolacerta martinezricai* is considered to be a valid taxon in need of urgent conservation action—the total population size is estimated to be less than 50 individuals.

Translocation of Gila Monsters in Arizona

Previous studies of translocation in snakes have reported low success rates. Several agencies currently translocate Gila Monsters (*Heloderma suspectum*) from large cities in Arizona, but the effects of this process are unknown. The authors responded to calls for nuisance animals, implanted passive integrated transponders and radio transmitters into the animals, and either translocated them (N = 15) or released them 200 m from the site of capture (N = 9). Test subjects were located every 2–5 days, and their location and behavior were recorded. All lizards released less than 1000 m from the site of capture returned within 30 days. However, all translocated lizards that failed to return were lost (presumably dead) or died, suggesting that translocation may have detrimental effects on some individuals. Moreover, translocated individuals had nearly five times higher mean daily movements compared to non-translocated individuals, which may have contributed to higher predation rates in translocated lizards. The authors conclude that translocation is not a satisfactory solution to the problem of "nuisance" animals.

Multiple Paternity in *Lacerta vivipara*

Several studies have suggested multiple paternity in lizard mating systems based on behavioral observations, but few researchers have demonstrated this phenomenon with molecular evidence. The authors used six polymorphic microsatellite markers to examine paternity in six populations (four captive, one highland, one lowland) of *Lacerta vivipara*. Considering all loci, none of the six populations differed from Hardy-Weinberg equilibrium. The number of multiply sired clutches was 50% or greater in all populations, and the mating system was not affected by environmental or population factors. The authors suggest multiple paternity is related to conflicting male-mate strategies in territorial species, but because *L. vivipara* males are not territorial, additional hypotheses should be explored in future studies.

Life-History Variation of *Sceloporus undulatus*

Studies of life-history evolution have been advanced by phylogenetic comparative analyses in recent years. However, few of these analyses have been attempted at the intraspecific level. The authors used a previously published molecular phylogeny of *Sceloporus undulatus* to examine intraspecific life-history variation. Fourteen populations of *S. undulatus* with good life-history information were examined along with one population each of *S. occidentalis, S. virgatus,* and *S. woodi.* Data were analyzed with independent contrasts and phylogenetic autocorrelation. The data indicated body size is an important correlate of life-history variation, but there are no important phylogenetic effects on life-history variation in *S. undulatus*. The authors suggest future studies of life-history variation are likely to vary by taxon and traits that are analyzed.

Conservation of Honduran Amphibians and Reptiles

Although the greatest diversity of life exists in the tropics, this region also has the greatest rate of human population growth. As currently understood, Honduras contains 334 species of amphibians and reptiles, and an additional 20 species are likely to occur there. Forty-one species of amphibians are endemic to Honduras, of which seven have "disappeared" and another 13 are declining; less than half of the amphibian taxa known from Honduras are stable. The authors used a set of gauges (e.g., extent of geographic range and ecological distribution) to establish a set of conservation priorities for the remaining Honduran herpetofauna. The authors classified 103 species of amphibians and reptiles as high priority, 154 species as intermediate priority, and 71 species as low priority. To offset the threats to the herpetofauna, the authors suggest expanding and improving the system of biotic reserves in Honduras as soon as possible.

"If destiny brings you to the far end of the globe, nature will surround you constantly with its production, its Phenomenon, and marvels. Do not ever renounce going to the purest of all sources."

"When science will have spread its domain, man will interrogate nature in the name of time and time in the name of nature. So many fertile comparisons will come to mind."

Bernard-Germain-Étienne de la Ville-sur-Illon, Compte de Lacepède (1798 and 1800)

"The cube, indeed a straight line of any kind, is unbiological."

Heini Hediger (1970:21) on artificial shapes such as cubical cages in zoos

Carl Hagenbeck (1844–1913) opened his Tierpark at Stellingen, Germany in 1907 and developed the first exhibits without bars for zoos (Kreger 2001; Reichenbach 1996). He served as a design consultant for zoos throughout the world and his philosophies are incorporated even today when new animal displays are planned. In the zoo and aquarium community, the Hagenbeck name is associated with naturalistic exhibitry and there is a perception that he was the first to envision a zoo without bars, nestled in a naturalistic setting. In reality, over a century earlier, Bernard-Germain-Étienne de la Ville-sur-Illon, Compte de Lacepède[1] (1756–1825; Fig. 1), the French naturalist known for his herpetological work, published several seminal papers on zoo history, philosophy, and design that discussed open exhibits and spaces. These publications are virtually unknown. To give Count de Lacepède the recognition he deserves, we have translated portions of his papers from French to show how enlightened he was at the beginning of the nineteenth century. It is interesting that zoo managers struggle today to grasp and implement concepts identified by Lacepède so long ago.

Fig. 1. Portrait of Count de Lacepède. Courtesy of Kraig Adler.

Lacepède was disturbed by the way animals had been treated in the past and how little proper care had improved. He wrote, "It is only very recently that liberty and reason have started to reign over a part of Europe; almost all the menageries that we see on that portion of the globe are still similar to those of the Roman despots. . . . They counted among the attributes of the empire, those narrow edifices, those tight lodges where they are kept, mutilated, degraded, denatured."

Lacepède had a clear idea of the proper mission of zoos and the three roles that these institutions should play: "Three objects are the principal aim of an establishment. The first is to satisfy the curiosity of the public by giving an easy and durable instruction without seeming so to show the habits of animals, to portray the species that Pliny, Linné, and Buffon transmitted to us, to substitute the attitudes of constraint to movements with a sort of independence. The second of those three objectives is to give to the naturalist the true means to perfect zoology by means of the menageries, and the third, to serve society most directly by acclimatizing wild animals reclaimed from the wild." An important point here is that Lacepède understood that zoo visitors could have a pleasant experience and learn something about animals in a nonthreatening way. The choice of the words ". . . to serve society most directly by acclimatizing wild animals reclaimed from the wild" and "greatest utility for man" used below suggests that he was an early thinker about the notion that zoos could be used as acclimatization facilities for wild species that might be domesticated or tamed and be of some "utilitarian" use for humans. The world's first acclimatization society was the Société Zoologique d'Acclimatation, founded in Paris in 1854 (Gillbank 1996). The founding president was Isidore Geoffroy Saint-Hilaire, professor of zoology at the Muséum national d'histoire naturelle and director of the Ménagerie (created in 1793). In 1860 Isidore and his son, Albert Geoffroy Saint-Hilaire, opened Jardin Zoologique d'Acclimatation, west of Paris (Osborne 1996). With reptiles, Henry Fitch (1980) warned captive managers about changes induced by captivity: "Thus, captivity will result in intensive selection, molding the animal in a manner quite different from that followed in its natural environment. The final product will be an animal much better adapted to live in close association with humans, in the home or laboratory, but less well adapted for life under natural conditions." Clearly, the effects of captivity on amphibians and reptiles, especially when reintroductions or other interventions are considered, need to be carefully investigated beforehand (see Chiszar et al. 1993; Dodd and Seigel 1991).

Lacepède was associated with La Ménagerie at the Muséum. Most herpetologists are familiar with Lacepède's name through his monumental tome which was the first to cover amphibians and reptiles of the world, "Histoire Naturelle des Quadrupèdes Ovipares et des Serpens," published in 1788–1789. Based in part on his experiences at the Ménagerie, he formulated a plan for the ideal menagerie: "One will be able to compare this enormous menagerie with the outdoors where the different animal species enjoy all the liberty that it is possible to give them without danger for the numerous spectators, who are also often imprudent, where

they will find a roof and care and where living among plants and trees of their country, shaded at least by vegetation as similar as that that can be found in their country, where they can play and their movement unimpeded, where they do not feel the exile nor the lack of their independence, where they will present to the observer the true picture of what they are like in their environment in the most remote countries of the globe."

Lacepède understood the integration of scientific inquiry into the operations of a zoo, as made clear by several selected passages in his 1801 publications: "It is through the help of such menageries that we will be able to create the science of animal physiognomy more real than that of human physiognomy because their pantomime does not express ideas and only depicts sensation and not ever being altered by pretenses is simpler, stronger, and truer." He continues. . ."The more or less great sensibility to the climatic conditions, to the different elements, the odor, the color, the sonorous impression, the mode of breeding, the time of the pregnancy, the duration of incubation, etc. . ." It is important to remember that the science of ethology did not exist at that time. What is also remarkable is that he understood how observations on behavior, reproduction, nutritional needs, and longevity could be accomplished in a zoo, for he said ". . . Let us keep species which can be of the greatest utility for man and let us give them wide living quarters, durable and best suited for their habits so that they can be observed fruitfully so that one can find the most adaptable nourishment which is most suited to their organs. Also, so that one can find their breeding habits, the number of their litter, the nature of their affection, the violence of their appetite, the length of their life span." Interestingly, Nobel laureate Konrad Lorenz reinforced Lacepède's vision a century and a half later (1952:73): "By keeping a living thing in the scientific sense we understand the attempt to let its whole life cycle be performed before our eyes within the narrower or wider confines of captivity."

Zoo workers should maximize the utility of their living collections by preserving specimens upon death and placing them in a suitable depository. Lacepède addresses this issue: "When an animal dies, it is immediately brought to the laboratory of anatomy. There the skin is taken and sent to the laboratory of zoology where the professor has it mounted if it is not yet on exhibit. Then we prepare the pan, and we put in one pan all the fleshy parts which one intends to preserve. We do not even neglect to look if there is not in the body of the animal some intestinal worms, which could lead to new observations." In this passage, Lacepède offers suggestions to the zoo pathologist as well. According to Kirchshofer (1968:288), Max Schmidt, a veterinarian and director of the Frankfurt Zoo from 1859 to 1885, "initiated the post mortems (sic) on zoo animals."

FIG. 4. Cover of "Le Monde Illustré" published 24 October 1874 showing reptile display and inhabitants at La Ménagerie Jardin des Plantes in Paris. Courtesy of Jean-Luc Berthier, Jardin des Plantes Archives.

FIG. 2. Undated illustration, possibly around mid-1870s, of interior of reptile building at La Ménagerie Jardin des Plantes in Paris. Credit: provided by Jean-Luc Berthier, Jardin des Plantes Archives.

Consider how stunning Lacepède's ideal zoo would be if it were ever actualized in totality: "The garden spreads over a surface which is rectangular and measures more or less thirty-six acres and offers a few elevations. Two little artificial rivers cross the terrain for all its length and end in a series of little lakes of irregular contours. Between the two sinuous little rivers an elevated path is used by the visitors; on each side of the bed of the double river the terrain rises slightly and irregularly and is provided with small hills and rocks. The park is planted with trees and appropriate bushes. Some parts are covered with sand. The slopes are divided in several enclosures of irregular dimensions surrounded by fences which go down to the water and are hidden by vegetation. The river is enlarged in front of those enclosures to allow animals to bathe and the edge is a little inclined in order to facilitate their access to the water. The night lodges for carnivores are hidden by rocks. For most of the species shelters are provided. The bird cages

are spacious and contain small trees and artificial rocks. There are lakes for fishes, aquatic turtles, sea lions, and especially aquatic birds, which are also allowed on certain parts of the rivers. Place is even provided for the breeding of worms and mollusks.

The zoological park so conceived is not an accumulation of buildings or birdcages or cages with bars but it constitutes a true scenery. The plantations offer plenty of natural habitats of most of these exhibited animals. As much as possible one will use as enclosures natural obstacles, among others, a combination of water surface and of different levels, for instance, an elevated path. Thanks to the sloping terrain the animals are not in moats but are the same level or almost the same level as the spectators." The Count identified an important issue relevant to zoo herpetologists. Presently, many zoo administrators are enamored with the rare and expensive – the so-called charismatic mega-vertebrates – so places for breeding worms and mollusks are rarely incorporated into master plans; amphibians and reptiles suffer the same fate. To prove this point, consider how few new herpetological facilities are being planned or significant resources directed into herpetological programs. Accordingly, there is a disturbing trend for building unimaginative and uninspiring zoogeographic exhibits with an occasional python, crocodilian, giant tortoise, or large lizard added as an afterthought. Retired director William Conway from the Wildlife Conservation Society in New York published a thought-provoking paper (1968, 1973) suggesting that the common bullfrog–widespread, small, inexpensive and ectothermic– can enlighten and educate the visitor very effectively. Today, a bullfrog display could be used as the perfect example to highlight amphibian biology, decline of amphibian populations worldwide, and the danger of introducing alien species. Unfortunately, zoo herpetologists have been rather ineffective in convincing their superiors that amphibians and reptiles are incredibly interesting and deserve a *prominent* place within the zoological garden or aquarium.

Lacep de was unable to implement his ideas, owing to the unstable political climate during the French Revolution and the lack of funds (Van den bergh 1962). His plans for outdoor displays at the M nagerie in Paris would have been suitable for some Temperate Zone animals, including amphibians and reptiles, but exotic taxa require indoor exhibits with stable temperatures. During 1870—1874, a reptile building with a pavilion and two lage center exhibition halls was constructed (Figs. 2—3).This beautiful edifice exists today, still used as a reptile building.

Biographies of Lacepède, appointed the Grand Chancellor of the Legion of Honor by Napoleon, are available (Adler 1989; Van den bergh 1962).

Acknowledgments.—This publication is dedicated to Warren Iliff, who throughout his professional career has strived to build the ideal zoo and aquarium. Kraig Adler, Judith Block, Jon Coote, Lucian Heichler, Robert Hoage, and Ken Kawata reviewed early drafts of the manuscript. Jean-Luc Berthier provided illustrations from the Archives of the Ménagerie Jardin des Plantes. Smithsonian National Zoological Park Librarian Alvin Hutchinson was instrumental in locating important historical documents. Leslie Overstreet and Daria Wingreen from the Joseph F. Cullman 3rd Library of Natural History (Smithsonian Institution Special Collections Department) allowed access to the extensive Lacepède collection. Our interest in the Count's life was stimulated by reading the excellent article by H. K. Van den bergh.

Footnote: [1]We follow Adler (1989) in spelling Lacepède without the acute accent on the first *e*.

A Note on the Identity of Chuckwallas Inhabiting Isla Danzante, Baja California Sur

RICHARD R. MONTANUCCI
Department of Biological Sciences, Clemson University
Clemson, South Carolina 29634-0314, USA
e-mail: rrmnt@clemson.edu

There is disagreement concerning the taxonomic identity of chuckwallas inhabiting Isla Danzante, Baja California Sur. Isla Danzante is a land bridge island situated at 25°47'07"N latitude, and 111°14'59"W longitude, 2.61 km from the coastline of the Baja California peninsula and south of Isla Carmen. It has an area of about 4.64 km^2 (Murphy et al. 2002). In a systematic revision of the genus *Sauromalus*, Hollingsworth (1998) placed the continental *S. obesus* and the peninsular *S. australus* in the synonymy of *Sauromalus ater*. He also classified the chuckwallas from the southern gulf islands, including Isla Danzante, as *S. ater.* In a study of body size evolution and biogeography of chuckwallas, Petren and Case (1997) sequenced the cytochrome *b* gene from a number of continental and insular populations of chuckwallas. Their analysis revealed that a single chuckwalla from Isla Danzante was genetically similar to their samples of *S. slevini* from Islas Carmen and Monserrate (*S. slevini* also occurs on Isla Coronados, but that island was not sampled by the authors).

Grismer (1999, 2002) listed Isla Danzante among the islands inhabited by *S. ater.* Murphy and Aguirre-Leon (2002) called attention to the discrepancy between Grismer's classification of the chuckwallas from Isla Danzante and the molecular genetic evidence from Petren and Case (1997), and chose to recognize this insular population as *S. slevini*. The purpose of my study is to compare nuchal scalation and other characteristics in a limited number of specimens to determine whether the Isla Danzante population is more similar to *S. ater* or *S. slevini.*

Sauromalus slevini is considered to be generally intermediate in scalation between the spiny chuckwalla, *S. hispidus,* and the smaller-scaled *S. ater* from the southern gulf islands (Shaw 1945). In *S. slevini*, the nuchal scales are much larger than the median dorsal scales and are conical to strongly spinose (Grismer 2002; Shaw 1945). Also, above and slightly forward of the shoulder, there is a skin fold bearing a patch of enlarged, subconical scales (Hollingsworth 1998; Shaw 1945). In contrast, the nuchal scales in *S. ater* are usually tuberculate, flattened, or spinose, but only slightly larger than the largest median dorsal scales. Also, the antehumeral fold lacks a group of enlarged, subconical scales; instead the scales are subequal.

Sauromalus slevini and *S. ater* cannot be distinguished on the basis of meristic scale characters. The range limits of eight meristic characters overlap substantially between the two taxa (compare Tables 13 and 19 in Hollingsworth 1998). Discriminant functions analysis (based on these eight meristic characters) did not separate chuckwallas from Isla Danzante from the insular samples of *S. ater*. The sample from Isla Danzante fell within the dispersion polygon of the sample from Isla San Francisco (see Fig. 51 in Hollingsworth 1998).

I examined two specimens from Isla Danzante (BYU 34494–95, female and male respectively), and compared them with a series of seven *S. slevini* from Isla Carmen, and eight *S. ater* from Isla San Francisco. The two specimens from Isla Danzante are very similar to specimens of *S. slevini*, having nuchal scales that are conical to strongly spinose, especially in the male (Fig. 1). However, many of the nuchal scales in the male specimen show damage, and examination under a dissecting microscope revealed that they were abraded. During life, the lizard may have frequently used a rock crevice with abrasive surfaces, perhaps for predator escape. The scales on the antehumeral fold are conical in the male specimen, and merge with more spinose scales in adjacent areas of the dorsum. The female specimen lacks differentiated scales on the antehumeral fold of the left side, and the scales are only feebly enlarged on the right side.

The male specimen from Isla Danzante has a snout–vent length of 193 mm, which greatly exceeds maximum SVL of *S. ater* from the southern gulf islands, and falls within the upper decile SVL of *S. slevini.* Hollingsworth (1998, Table 4) provides maximum SVLs for these insular samples as follows: Isla Espiritu Santo (169 mm), Isla Partida Sur (171 mm), Isla San Diego (134 mm), Isla San Francisco (145 mm), Isla San Jose (156 mm), Isla San Marcos (164 mm), and Isla Santa Cruz (166 mm). Hollingsworth (1998) gives maximum SVLs for three populations of *S. slevini* as follows: Isla Carmen (188 mm), Isla Los Coronados (202 mm), and Isla Monserrate (209 mm). Petren and Case (1997, Table 2) provide upper decile SVLs for these populations as follows: *S. ater* from the southern gulf islands (163 mm; N = 111) and *S. slevini* from Isla Carmen (181 mm; N = 22).

There appears to be ontogenetic as well as sexually dimorphic variation in the development of the enlarged, spinose nuchal scales in *S. slevini*. The largest male examined (CAS 16127; 190 mm SVL) has greatly enlarged, spinose nuchal scales giving the lizard a more bristly appearance compared with smaller males (143–179 mm SVL). Three females examined (127–154 mm SVL) also have

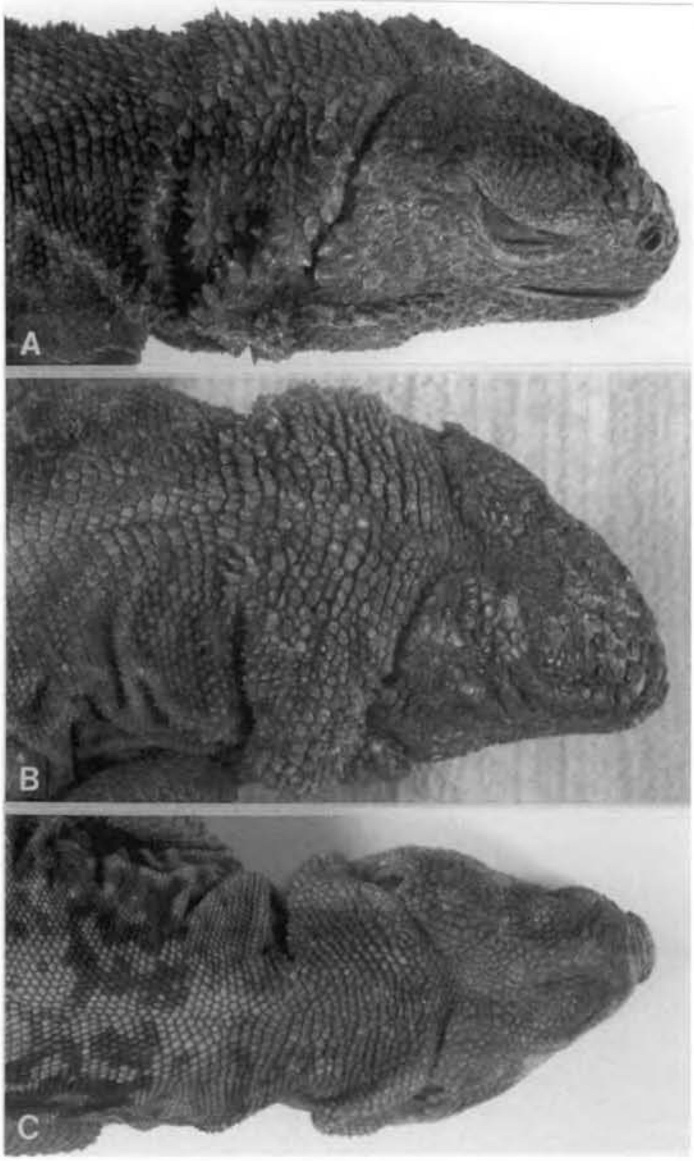

FIG. 1. Comparison of the nuchal scales of (A) *Sauromalus slevini* (CAS-SU 16127), male, from Isla Carmen; (B) *Sauromalus* (BYU 34495), male, from Isla Danzante, and (C) *Sauromalus ater*, (CAS 52708) from Isla San Francisco.

spinose nuchal scales that are less developed when compared with males.

There is also variation in the development of enlarged subconical scales on the antehumeral fold. In the largest male *S. slevini* examined, the scales on the antehumeral fold are spinose and merge with those on the nuchal area. In smaller males, and in females, slightly enlarged, rounded to subconical scales may be present on the antehumeral fold as a discrete group, surrounded by smaller scales. However, the degree of development of the scales on the antehumeral fold is variable among individuals, and may also differ between the left and right antehumeral folds on the same individual. The ontogenetic and sexually dimorphic variations in these characters have not been previously reported.

Hollingsworth (1998) recognized *S. slevini* and *S. klauberi* as sister taxa on the basis of three synapomorphies: enlarged scales on the antehumeral fold, spinous lateral fold scales, and absence of caudal bands throughout ontogeny. The group of differentiated scales on the antehumeral fold of *S. slevini* seems to foreshadow the further enlargement of these scales in *S. klauberi,* but except in the largest specimens, they lack the more spinose shape seen in the latter species.

In conclusion, the chuckwallas from Isla Danzante agree with *S. slevini* in terms of the relative size and shape of the nuchal scales, the presence of enlarged scales on the antehumeral fold, and the snout–vent length. The morphological evidence is therefore consistent with the gene sequence data from Petren and Case (1997), and this insular population should be regarded as *Sauromalus slevini.*

Acknowledgments.— I am grateful to J. W. Sites and W. Skidmore (Monte L. Bean Life Science Museum, Brigham Young University), and J. V. Vindum and R. E. Stoelting (California Academy of Sciences) for the loan of *Sauromalus* used in this study. I also thank Kenneth Petren for field data, Robert W. Murphy and two anonymous reviewers for comments on the manuscript, and David H. Lewis for photographic assistance.

Papua New Guinea National Museum, PO Box 5560
Boroko, Papua New Guinea

On 11 August 2000, during the filming of a documentary in Western Province, Papua New Guinea (PNG), the authors flew from Daru Island to the disused airstrip at Weam (141°07'E, 08°37'S), ca. 33 km E of the Indonesian border (Fig. 1). While searching among discarded metal sheeting on the edge of the Weam runway, we found a small *Antaresia* and two skin sloughs, likely to have come from the same snake, between two upright layers of corrugated sheeting (Fig. 2). The specimen is the first representative of the genus to be found in New Guinea and the first recorded outside Australia.

We tentatively identify this specimen as *Antaresia maculosa* (Fig. 3). It is a female measuring 480 mm snout–vent length, 525 mm total length. Characters of scalation were recorded according to Smith (1985) (Table 1). There are 253 ventrals, 48 subcaudals, and dorsal scale rows are 33-41-25. The scalation of the head is as follows: there are 10/10 supralabials with the fifth and sixth in contact with the lower margin of the orbit; 12/12 infralabials; two pairs of prefrontals with one smaller azygous scale on the midline; 4/5 loreals; 1/1 preocular; 3/3 postoculars; and 2/2 anterior temporals. The scale counts fall within the ranges reported for *A. maculosa* (Smith 1985). Barker and Barker (1994) report an average ventral+subcaudal count of 317.5 in northern Australian populations and an average of 301.3 in southern populations. The ventral+subcaudal count for the Weam specimen is 301, which unexpectedly associates it with the more southern populations in Australia. According to David Barker (pers. comm.), the pattern of the specimen discovered at Weam resembles the inheritable appearance seen in some captive-bred spotted pythons known as the "granite phase." We are not aware that this pattern type occurs in natural Australian populations of *A. maculosa*.

The presence of *Antaresia* in southwestern PNG provides further proof of the strong herpetofaunal links that exist between the southern Trans-Fly region of New Guinea and northern Australia. As recently as 10,000 years b.p. the two land masses were broadly joined by land, the Sahul Shelf, now submerged under the Torres Strait, allowing considerable interchange of floras and faunas. The overlap in reptile species has been well documented (Cogger 2000; De Rooij 1915; O'Shea 1996). Although the new specimen superficially differs in appearance from wild Australian *Antaresia maculosa*, presently there is insufficient reason to describe it as a new taxon because a) only one specimen was found and b) there

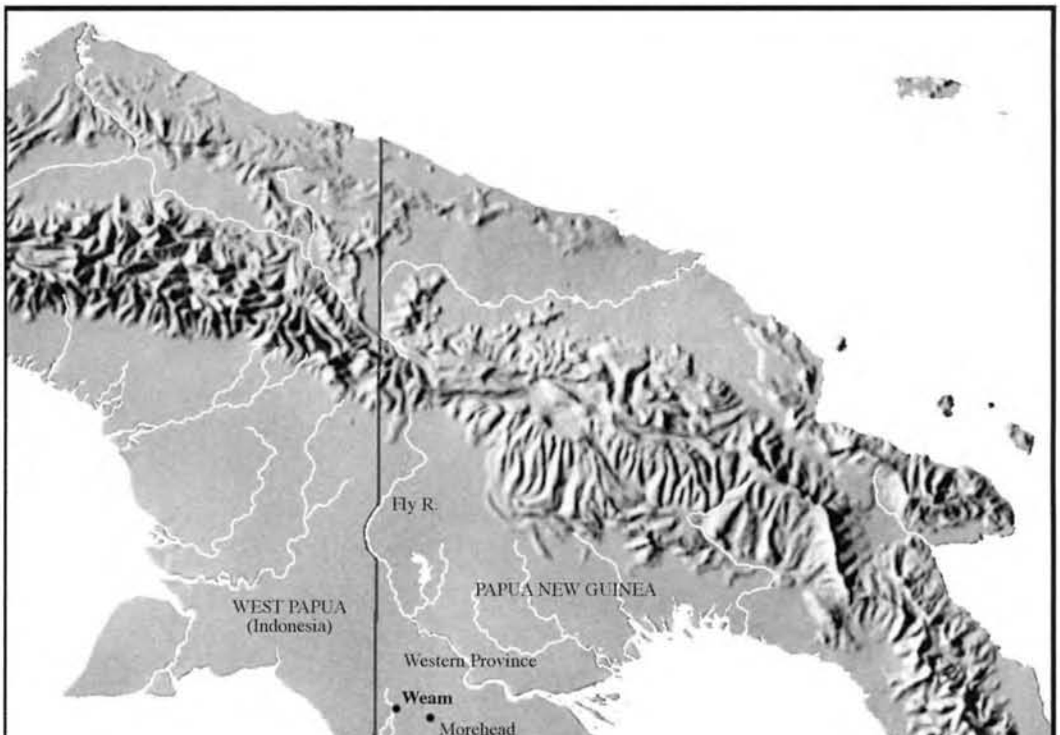

FIG. 1. Map of Papua New Guinea showing Weam (in bold) located in Western Province.

FIG. 2. Collection site of *Antaresia maculosa* at Weam Airstrip, Weam, Morehead District, Western Province, Papua New Guinea.

are strong zoogeographic links between Western Province, PNG and far northern Queensland. However this does not rule out the possibility that this New Guinea snake might represent a new species. Further fieldwork and DNA comparisons are needed to determine relationships of our specimen to those occurring in Queensland.

Many of the more remote areas of the Western Province of PNG remain poorly explored. The terrain is flat, heavily forested, and largely swampland or floodplain with numerous termite mounds, which makes fieldwork difficult. Weam is along the far western border of Papua New Guinea, near the Indonesian border and on the Bensbach River (Fig. 1). We were told that the airstrip has been closed for 10 years and had only been opened to facilitate our arrival and departure. Though August is generally dry season

FIG. 3. Specimen of *Antaresia maculosa* (PNGM 25085) from Weam, Western Province, Papua New Guinea. Top: dorsal view of head; lower: whole body view. Photos by Mark O'Shea.

TABLE 1. Comparison of features of *Antaresia maculosa* (based on Smith 1985) with the specimen of *A.* cf. *maculosa* from Weam, PNG.

Character	Australian *A. maculosa*	Weam specimen
Dorsal scales at neck	28–35	33
Dorsal scales at midbody	35–44	41
Dorsal scales at vent	22–28	25
Ventrals	246–287	253
Subcaudals	37–48	48
Ventrals + subcaudals	288–332	301
Supralabials	10–11 (11–12)	10
S/L contacting orbit	5th & 6th	5th & 6th
Infralabials	12–14	12
Pairs of prefrontals	2	2
Azgygous scale present	variable	yes
Loreals	3–10	4–5
Preoculars	1	1
Postoculars	3–4 (2–5)	3
Anterior temporals	3–4 (3–5)	2
Dorsal coloration	yellow-brown to dark brown	olive brown
Dorsal pattern	irregular rough-edged spots	dark irregular, rough-edged spots arranged in transverse rows
Scale iridescence present	yes	yes
Ventral color	immaculate off-white	immaculate off-white merging to light yellow
Head coloration	brown with spotted markings posteriorly	as body with single or fused dark spots on every scute, dark canthal and temporal stripe and off-white labials below
Color of iris	brown to orange or gold	dark orange

in Western Province, the 2000 wet season lasted well into July. Nevertheless, humidity levels were moderate (50–60%), and the environment was generally dry and warm (29–31°C). Though we have no direct evidence of the diet of this python in PNG, there were numerous geckos (*Hemidactylus frenatus*) between the same metal sheets.

The live specimen was left in the live collection at the Papua New Guinea National Museum and Art Gallery under the care of Ilaiah Bigilale. It has subsequently died and been accessioned into the museum collection (PNGM 25085).

Acknowledgments.—The finding of this python was recorded at the moment of capture during the filming of an episode of "O'Shea's Big Adventure" for Animal Planet. The episode, entitled "Tree Crocodile," was first transmitted in the USA on 10 December 2000. We gratefully thank David Barker and Gerry Swan for their advice, the film crew from Yorkshire/Associated Producers, the owners and employees of Bensbach Lodge for support in the field, Central Air Transport, and the Tondo Wildlife Committee and Councillor Lucas Mahuse of Weam village for permission to carry out filming and fieldwork within the Tondo Wildlife Reserve area.

Description of the Female of the Enigmatic Lizard, *Liolaemus heliodermis* (Iguania: Liolaemidae)

RAYMOND A. HERNANDEZ
and
ROBERT E. ESPINOZA
Department of Biology, California State University, Northridge

The lizard genus *Liolaemus* has experienced remarkable growth in recent years. In the past decade an average of four new species has been described each year and dozens more await description (Etheridge and Espinoza 2000). Given this trend, and recent estimates of cryptic diversity in some clades (e.g., Lobo and Espinoza 1999; Morando et al. 2003), *Liolaemus* may someday surpass even *Anolis* (sensu lato) in species richness. Currently, *Liolaemus* includes approximately 160 species. A recent molecular phylogenetic analysis (Schulte et al. 2000) of 60 species representing all major *Liolaemus* lineages recovered two similarly sized clades and corroborated the results of several morphological studies (reviewed by Etheridge 1995). One of these major clades, the *chiliensis* group, includes approximately 80 species and has been further divided into numerous subgroups (Etheridge 1995; Lobo 2001). One of these subgroups, the *elongatus-kriegi* group (sensu Morando et al. 2003; see also Cei 1979), has experienced recent growth with the addition of seven species since 2000 (Avila et al. 2003, 2004; Cei and Videla 2003; Espinoza et al. 2000; Espinoza and Lobo 2003). Moreover, molecular analyses of populations in southern Argentina suggest that the *elongatus-kriegi* group may include as many as three times the number of species currently recognized (Morando et al. 2003). Given their recent discovery and remarkable diversity, the natural and life history of most species belonging to this group is poorly understood.

Among members of the *elongatus-kriegi* group, *L. heliodermis* is likely the most enigmatic. This species belongs to a recently diagnosed clade (Espinoza and Lobo 2003) that consists of four species (*L. capillitas*, *L. dicktracyi*, *L. heliodermis*, and *L. umbrifer*; but see Avila et al. 2004 for a more inclusive definition). In contrast to the other three species belonging to this northern radiation, and to the *elongatus-kriegi* group on whole, *L. heliodermis* is an unusually rare lizard (Espinoza et al. 2000). The species was described from just three specimens: two adult males and a juvenile female. The coloration of male *L. heliodermis* is unlike that of virtually all other *Liolaemus*: black heads with vibrant sulfur-yellow torsos (see Espinoza et al. 2000 for a color illustration). Interestingly, the juvenile female paratype is brown, but because no adult female was available for study, only speculation could be offered regarding the occurrence and ontogeny of sexual dichromatism in this species. Documenting sexual dichromatism in *L. heliodermis* may be the first step toward revealing related aspects of the lives of these poorly known lizards because sexual dimorphism is absent in most other members of this lineage (Espinoza and Lobo 2003). Here we describe an adult female *L. heliodermis* to provide much needed information on variation in squamation of this enigmatic taxon. Second, we address the hypotheses posed by Espinoza et al. (2000) regarding the ontogeny and intersexual occurrence of sexual dichromatism in this species.

On 25 January 2000, an adult female *Liolaemus heliodermis* (deposited at the Fundación Miguel Lillo, Tucumán, Argentina; FML 8974) was found at km 98 on Ruta Provincial 307, Departamento Tafí del Valle, Provincia de Tucumán, Argentina, just 3 km from the type locality. The specimen was dead and had been trapped in the freshly paved asphalt of this provincial highway (G. Scrocchi, pers. comm.). The lizard likely succumbed to exposure after adhering to the tar (Hubbs and Walker 1947). Before preservation, gasoline was used to remove tar from the lizard, which resulted in loss of some scales. The specimen is otherwise in good condition with the exception of the loss of approximately three quarters of the tail. Notes on color were taken prior to preservation.

The following description adopts terminology for squamation from Smith (1946) as modified by Espinoza et al. (2000) and Espinoza and Lobo (2003). We followed Frost (1992) for definitions of neck folds. Snout–vent length (76.05 mm), tail length (13.55 mm, autotomized), axilla-groin distance (34.05 mm). Head (anterior border of auditory meatus to the tip of the snout 17.94 mm), head width (anterior border of auditory meatus 13.64 mm), snout length (posterior margin of canthal to tip of snout 5.14 mm), intraorbital distance 4.34 mm, tibial length (16.23 mm), foot length

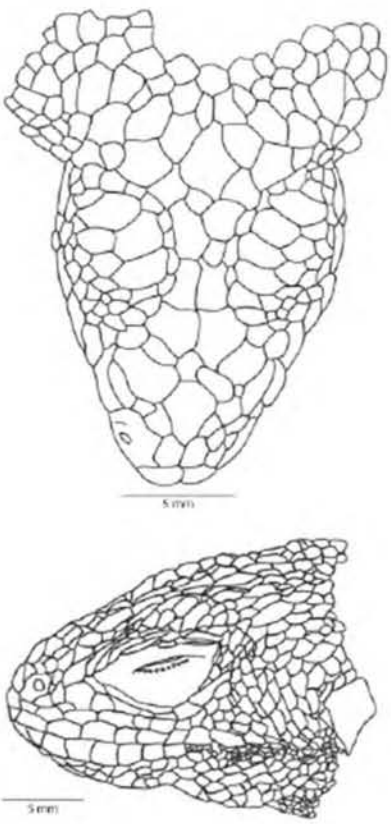

FIG. 1. Dorsal and lateral views of the head of an adult female *Liolaemus heliodermis* (FML 8974).

(22.34 mm).

Dorsal and lateral views of the head are provided in Fig. 1. Dorsal head scales smooth, 15 between occiput at the level of the anterior border of auditory meatus and rostral. Nine smooth temporals, most with a scale organ at their posterior margin. Interparietal subpentagonal, of similar size to the parietals, surrounded by seven scales. Frontal scale divided longitudinally, forming two scale rows between circumorbitals. Five scales between frontal and rostral. Two postrostrals. Each postrostral with 12–13 scale organs. Supraorbital semicircles complete. Four/five (right/left) enlarged supraoculars. Five scales between frontal and supercilliaries. Five/six flat, elongate superciliaries. Canthal separated from nasal by one or two scales. Loreal region flat. Eight scales surrounding nasals. Nasal in slight contact with rostral. Eight/nine lorilabials, fourth through eighth/nine in contact with subocular. Six/seven supralabials. Fourth/fifth supralabial curved upward posteriorly but not in contact with subocular. Infralabials five, slightly taller than supralabials. Four internasals. Orbit with 16 upper and 15 lower ciliaries. Orbit diameter 3.5 mm (measured between upper and lower ciliaries). Subocular scale elongate. Preocular unfragmented. Longitudinal ridge along upper margin of the three ocular scales. Rostral scale wider (3.88 mm) than high (1.39 mm) fragmented along left side. Mental wider (2.03 mm) than long (3.46 mm), followed posteriorly by two rows of 4/5 chinshields. Chinshields in contact with first infralabial. Scales of throat between chinshields juxtaposed, becoming slightly imbricate toward the auditory meatus. Fifty gulars between auditory meatus. Three/four scales along anterior border of auditory meatus project outward. Auditory meatus higher (4.12 mm) than wide (2.28 mm). Lateral scales of neck granular. Subdermal fat bodies give inflated appearance to neck region. Antehumeral fold distinct. Rictal, postauricular, and longitudinal folds present but less conspicuous than antehumeral. Thirty-nine scales between auditory meatus and antehumeral fold (counted along postauricular and longitudinal folds).

Scales of neck region smaller than dorsals. Sixty-four dorsal scales between occiput and anterior surface of thighs. Dorsal body scales round to rhomboidal, very weakly keeled. Fifteen to 17 longitudinal keeled scale rows over dorsum of trunk. Scales become increasingly rounded laterally and along flanks. Sixty-nine scales around midbody. Ventral scales of similar size to dorsals, 110 between mental and mid-thigh. Ventral surface of thighs with enlarged, laminar imbricate scales anteriorly, abruptly changing to smaller granular scales posteriorly at mid thigh. No precloacal pores. Fourth finger with 23 tridentate, subdigital lamellae. Claw relatively straight, moderately short, pointed, opaque brown. Fourth toe with 28 subdigital lamellae. Claw similar to that of fourth finger.

At the time of collection the specimen was dead, but apparently not for long (G. Scrocchi, pers. comm.), so its color in life was probably reasonably well preserved. Dorsally, head to near insertion of the forelimbs black. Laterally, head black with some barely noticeable gray scales. Throat charcoal black with black margins and many small, irregularly dispersed black spots. Dorsal torso gray with many small yellow flecks. Vertebral field (sensu Lobo and Espinoza 1999) much darker than remainder of dorsal body. Color much lighter from hind limbs to portion of tail not autotomized than for remainder of dorsal body. Dorsal forelimbs black with yellow flecks. Hind limbs much lighter than forelimbs. Ventrally gray, abdominal region gray with larger flecks of black and laterally with flecks of yellow. Ventral forelimbs gray with very few yellow flecks; ventral hind limbs much lighter. Overall the brightness of the yellow on this specimen was considerably less vibrant or extensive on the trunk compared to the two males described previously (G. Scrocchi, pers. comm.).

After 2.5 years in preservative (70% EtOH) the color is somewhat faded: black extends to shoulders, beyond which, dorsal scales grade to pale cream-yellow on torso. Yellow color of torso extends to first quarter of tail (last three quarters of tail autotomized). Ventral surface light gray with dark gray to charcoal flecks becoming denser laterally. Flank with larger charcoal gray marks flecked with scales of cream-yellow. Throat darker than belly, densely flecked with gray marks especially along perimeter. Ventral surfaces of thighs with a longitudinal band of pale cream scales.

The only other known female of *L. heliodermis*—a juvenile (paratype; FML 6007)—has a brown head and lighter brown dorsal torso with flecks of cream-colored scales. This is in stark contrast to the black head and sulfur-yellow torso exhibited by adult males of this species (Espinoza et al. 2000). Consequently, at the time of the original description, only speculations could be made about the development and occurrence of sexual dichromatism of this species. Three possibilities were offered to account for the marked differences in coloration in this species: (1) males and females are sexually dichromatic, wherein females retained the brown coloration of juvenile described above, (2) the species is not sexually dichromatic, and the bright coloration develops ontogenetically in both sexes, or (3) sexual dichromatism is present and develops ontogenetically for both sexes, perhaps with females

becoming less brightly colored than the males. The description of the adult female *L. heliodermis* provided above suggests that sexual dichromatism, although present, is not as dramatic as would be the case if the juvenile coloration were retained into adulthood for females. Although females undergo a dramatic change in coloration ontogenetically (brown → yellow), the yellow coloration could brighten to levels not detected in specimens collected to date. For example, females may develop brighter coloration when gravid, as is apparent in other *Liolaemus* (Espinoza and Lobo 2003; Etheridge 2000; R. E. Espinoza, pers. observ.) and numerous other iguanian lizards (Cooper and Greenberg 1992). Consequently, the apparent dichromatism, at least in color saturation, may be apparent only during portions of the breeding season. Collection of a juvenile male is required to resolve the question of the ontogeny of male coloration. We predict, as in females, juvenile males are brown and also undergo an ontogenetic change in coloration.

Acknowledgments.—We thank G. Scrocchi for bringing this specimen to our attention and for providing a color photo and a description of its coloration in life. We are grateful to S. Kretzschmar (FML) for curatorial support, J. Hogue for help with the camera lucida, and G. Köhler for comments on the manuscript.

Reptiles are similar to other vertebrates in that they show both behavioral and physiological stress responses to a wide variety of stimuli (reviewed by Greenberg and Wingfield 1987; Lance 1990; Guillette et al. 1995; Wingfield and Romero 2001; Greenberg 2002; Greenberg et al. 2002; Moore and Jessop 2003). Frequently reported stressors include extreme temperature (Jessop et al. 2000), crowding (Hayes 1997), social dominance (Alberts et al. 1994; Matter et al. 1998; Schuett et al. 1996; Greenberg 2002, 2003), starvation (Romero and Wikelski 2001), as well as a range of anthropogenic factors (Hofer and East 1998) including capture and handling (Moore et al. 1991; Kreger and Mench 1993; Cash et al. 1997; Lance and Elsey 1999; Cree et al. 2000; Moore et al. 2000; Gregory and Schmid 2001; Mathies et al. 2001; Franklin et al. 2003; Jessop et al. 2003).

The hypothalamo-pituitary-adrenal (HPA) axis is unquestionably the best-studied physiological system concerning the stress response (Selye 1973), and there is a relatively long history on adrenal hormones (glucocorticoids) in reptiles (Greenberg and Wingfield 1987; Lance 1990). Cortisol and corticosterone (CORT) are adrenal glucocorticoids released in response to stressors, and when elevated have important metabolic functions in converting stored energy (e.g., lipids and proteins) to available glucose for escape or defense (Dallman et al. 1995; Guillette et al. 1995). Chronically high levels, however, can have profoundly negative

downstream effects on immune function (Guillette et al. 1995; Moynihan 2003). The primary glucocorticoid in reptiles is CORT (Greenberg and Wingfield 1987)

Researchers interested in measuring levels of circulating CORT for studies on metabolism or reproduction face the problem of obtaining blood samples quickly to avoid adversely influencing "true state" levels through handling stress. It is thus important to understand the influence of handling stress on CORT levels. A quantitative sense of the timing of the CORT response during handling permits evaluation of handling techniques as potential confounding variables in the analysis of CORT itself, other steroids such as testosterone (Lance et al. 2004), and a wide range of physiological parameters immediately removed from but affected by elevated levels of CORT (e.g., immune responses) (Guillette et al. 1995; Moynihan 2003)

The goal of this study was to determine whether certain handling procedures cause a significant CORT response in a laboratory colony of male Western Diamond-backed Rattlesnake (*Crotalus atrox*) derived from the wild. The measurements of CORT we report are not intended to stand as surrogate values for subjects living in the wild. Rather, they denote important baseline data for laboratory analyses and prospective field studies.

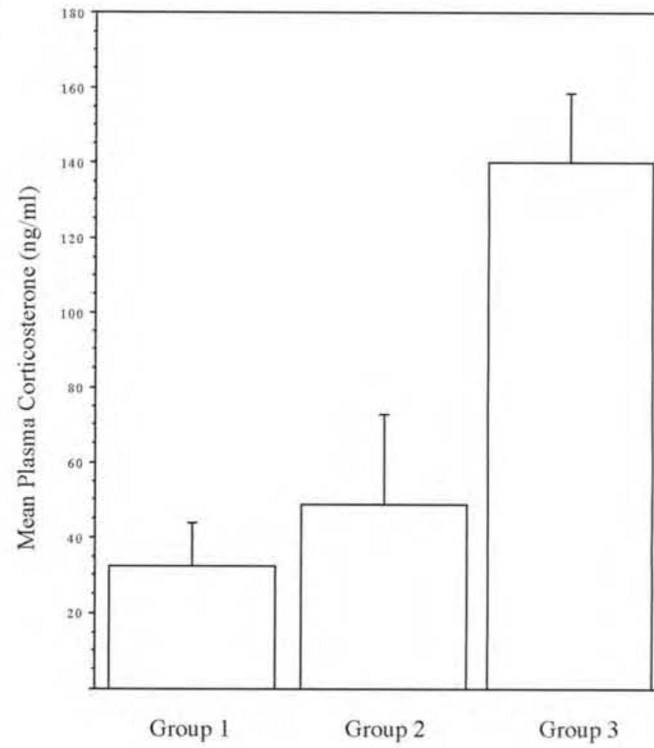

FIG. 1. Mean (± 1 SE) concentration of plasma corticosterone (ng/ml) for 17 adult male *Crotalus atrox* in three independent experimental groups. Control Group: Group 1 = no handling stress and blood sampling at 5-min post arena exposure. Treatment Groups: Group 2 = 5-min handling stress and blood sampling at 15-min post-handling. Group 3 = 5-min handling stress and blood sampling at 30-min post-handling.

MATERIALS AND METHODS

Subjects.—Seventeen adult male Western Diamond-backed Rattlesnakes (*Crotalus atrox*) were used. All subjects were long-term (3–4 years), healthy captives (housed in the Life Sciences Department, Arizona State University West, Animal Care Facility), and were collected as adults from several areas in central Maricopa County, Arizona, near the vicinity of Phoenix. Mean (± 1 SE) snout–vent length (SVL) was 89.1 ± 2.39 cm, range 74.0 to 98.0 cm, and mean (± 1 SE) body mass was 480.45 ± 32.81 g, range 278.80 to 639.3 g. Subjects were housed individually in glass enclosures (91 L x 30 W x 25 H cm) fitted with screen covers, with the front end heated by commercial heat tape (8 cm wide; 32°C) during photophase. Newsprint was used as a floor covering. Artificial lighting (eight 40 W fluorescent tubes) positioned 3 m above the cage was electronic timer-controlled to simulate natural (Arizona time) photoperiod year round. Laboratory rodents were offered weekly during the active season (March through October), and water was available in glass bowls *ad libitum*.

Testing procedures.—Experimental procedures for testing handling stress were performed in the laboratory. Handling procedures involved the following. The experimental subjects were randomly selected and placed in three groups: group 1 (N = 5), the control, and two treatment groups, group 2 (N = 5) and group 3 (N = 7). Testing occurred in a large observation arena (2.5 L x 1.5 W x 1 H m). The arena floor had three commercial strips of heat tape (16 cm wide; 32°C) running its length, and on top of them newsprint covered the entire arena floor. Each trial (N = 12) involved placing a single subject in the middle of the test arena, and each was gently and consistently (every 5 sec) prodded and grabbed with a commercial snake grabber (snake tongs; 1 m in length) for a total time of 5-min. Following this procedure they were immediately returned to their individual permanent enclosures, and bled at 15-min (group 2) and 30-min (group 3) post-handling, respectively, and returned to their permanent enclosures. The control (group 1) involved placing subjects (N = 5) into the arena for 5-min but they were not prodded nor grabbed. They were bled immediately after removal from the arena, and returned to their individual permanent enclosures. All tests occurred during the late morning of 24 March 2000.

Collection of blood and plasma.—Subjects were gently removed from their individual permanent enclosures, quickly restrained in a standard squeeze-box, bled, and returned to their enclosures. The entire process required 1–3 min. Blood was obtained from tail vessels using sterile 1.0 ml tuberculin syringes (25-G5/8") treated with porcine-derived heparin sodium (1,000 units/ml). Blood was immediately placed on ice (Taylor and Schuett 2004), followed by centrifugation for 4-min at 6000 rpm. Plasma was individually collected in 1.5 ml centrifuge tubes and stored in an ultra-low freezer (- 80ºC) until radioimmunoassays (RIAs) could be performed (< 1 year).

Radioimmunoassay of plasma.—The general procedures for conducting RIAs for measurement of CORT are published elsewhere (Schuett et al. 1996; Schuett and Grober 2000), but will be briefly described below. RIA kits were used (ImmuChem double antibody corticosterone, RIA I; ICN Biomedicals, Inc.). Validation for the RIA was by quantitative recovery and parallelism. Quantitative recovery of CORT added to snake plasma was 100%, and parallelism was demonstrated between the inhibition curve for the standards and dilutions. In this analysis CORT did not require an extraction procedure. The minimum detectable concentration was ≥ 50 pg. Samples (N = 34) were analyzed in duplicate in one RIA. The intra-assay coefficient of variation was 2.4%. All CORT values are pre-

sented as arithmetic means ± 1 SE (ng/ml).

Statistical analyses.—Prior to performing statistical tests (StatView 5.01, SAS Institute, Inc.), data were inspected for outliers, normality (skewness and kurtosis), and equality of variance. Outliers were not detected, and conditions for normality and equality of variance were met. Because of the tendency of snakes with larger body mass to have relatively higher levels of circulating gonadal steroids (Schuett et al. 2001a, b; 2002; Taylor and Schuett 2004), we inspected body mass as a potential covariate for ANCOVA. Although body mass of individuals ranged widely, mean body mass of the three treatment groups was not significantly different (ANOVA, $F_{2,14} = 0.854$, $p = 0.447$), and linear regression showed no significant relationship between body mass and levels of plasma CORT (Group 1: $r^2 = 0.411$; ANOVA, $F_{1,3} = 2.097$, $p = 0.243$. Group 2: $r^2 = 0.515$; ANOVA, $F_{1,5} = 5.305$, $p = 0.070$. Group 3: $r^2 = 0.236$; ANOVA, $F_{1,3} = 0.926$, $p = 0.410$.). Accordingly, ANOVA was used instead of ANCOVA. All tests were two-tailed; the α-level of significance was set at $p < 0.05$.

Results

Mean (± 1 SE) concentrations of plasma CORT in the three experimental groups of *C. atrox* are presented in Fig. 1. ANOVA demonstrated a significant treatment effect ($F_{2,14} = 9.829$, $p = 0.0022$), and post hoc (Fisher's PLSD) analyses showed that the mean concentration of CORT in group 3 (blood obtained at 30-min post-handling) was significantly greater than in group 2 (blood obtained at 15-min post-handling) or in group 1 (control). There was no significant difference ($p = 0.578$) in the mean CORT levels between group 1 and group 2. Therefore, in adult male *C. atrox* subjected to mild handling stress, the response time for detection of significantly elevated levels of CORT is at least 30-min post-handling.

Discussion

The present data show that wild-collected adult male *C. atrox* held long-term (3–4 years) in a laboratory situation show a relatively rapid and significant CORT response to mild handling stress at 30-min post-handling. Our results should not be used as surrogate values for free-ranging subjects, but they emphasize the importance of obtaining blood for CORT measurements relatively quickly to obtain "real state" values. The duration of capture and the time required to obtain blood are potential confounding variables in analyzing CORT and other steroid hormones (Moore et al. 1991; Lance et al. 2004). If captivity has the influence of reducing the time course of the stress response due to habituation, we suspect that free-ranging *C. atrox* might be even more sensitive to handling stress (i.e., show a greater and more rapid CORT response). We do not, however, have data to support this view in snakes. Interestingly, the subjects in this study showed no signs of behavioral habituation with respect to defensive behaviors (e.g., striking, rattling) despite being removed from the wild as adults for 3–4 years. In a non-reptilian example, a battery of stress tests using wild and domestic cavies (Rodentia, *Cavia aperea*) showed that long-term breeding (30 generations) in captivity did not result in significant changes in behavioral and CORT responses (Künzl et al. 2003). A similar study on snakes and other reptiles would be valuable for comparison.

Other researchers investigating handling stress and CORT levels in snakes obtained results similar to ours. Kreger and Mench (1993) used three common handling techniques to investigate stress responses in captive Ball Pythons (*Python regius*). Although their study had potential problems because of repeated-sampling of a small number of subjects (N = 4), none of the short-term (10-min) handling procedures evoked a significant elevation of plasma CORT. A study on Brown Treesnakes (*Boiga irregularis*) in Guam showed that protracted (1 night) confinement stress in traps showed significantly elevated plasma CORT, and there was limited evidence that other sex steroids were affected negatively (Mathies et al. 2001). Moore et al. (2000) showed that capture stress in male Red-sided Garter Snakes (*Thamnophis sirtalis parietalis*) did not result in suppression of courtship. There was, however, a significant elevation in plasma CORT, as well as a significant negative correlation between levels of plasma CORT and testosterone (Moore et al. 2000). Nonetheless, Moore et al. (2000) suggested that the behavioral stress response is uncoupled from the hormonal stress response during mating to maximize reproductive success. All of the above examples clearly show that capture and handling stress can elicit a CORT response, and that there are complex issues concerning species differences, as well as seasonal and sex differences.

We would like to specify several limitations of this study and point to further research. First, we have few concerns regarding diel effects in this study based on the fact that all sampling occurred in a narrow time frame in a single day (Cree et al. 2000; Summers and Norman 1988; Tokarz et al. 1998; Tyrell and Cree 1998). Although we have not determined in either captive or wild adult male *C. atrox* whether or not plasma CORT concentrations show diel patterns, we do know that there is no significant variation in plasma CORT during their active season (Mar.–Oct.) (Taylor et al. 2004). Second, we have not tested adult female *C. atrox* for CORT responses to handling. Several studies have demonstrated that there are sex differences in the CORT response (Lance et al. 2001; Mathies et al. 2001; Moore and Jessop 2003), and in females differences can be seasonal and influenced by reproductive states (Cree et al. 2000; Lance et al. 2001). During parturition, for example, mean plasma CORT levels in *C. atrox* are exceedingly high (> 350 ng/ml) yet their behavioral state appears to be stress-free. In fact, females appear to be tranquil and unremarkable (Schuett et al., *in press*). Third, there are few data on stress in juvenile reptiles. Behavioral (e.g., social) stressors can affect growth and immunocompetency (Alberts et al. 1994; Guillette et al. 1995). Finally, because our data set is limited to captive animals, tests of handling stress in free-ranging *C. atrox* across their active season and spanning different contexts (e.g., reproductive vs. non reproductive) would provide a broader range of knowledge.

In conclusion, our results on handling stress have direct utility for investigations of CORT in *C. atrox* in a wide range of laboratory-based studies of physiology and behavior (Guillette et al. 1995), as well as in free-ranging populations. Moreover, there are implications for studies of stress and CORT levels in the collection of free-ranging individuals for commercial uses, such as in rattlesnake roundups (Fitzgerald and Painter 2000).

Acknowledgments.—We greatly appreciate assistance in the field from the Schuett family (Laura, Laudon, and Emory), Jack O'Leile, and Ryan Sawby. Neil Greenberg and two anonymous referees made valuable comments to improve this paper. Funding was by a Research Incentive Award, and a Scholarship, Research Creative Activities Award (Arizona State University) to GWS. Zoo Atlanta generously provided funding and assistance in the preparation of this manuscript. The present research was approved by the IACUC at Arizona State University (98-429R to GWS).

Aural Abscesses on Florida Box Turtles are Associated with Abnormally Wet Winters

C. KENNETH DODD, JR.

Box turtles (*Terrapene*) frequently have been reported with aural abscesses, correctly referred to as an abscessation of the middle ear. The abscesses produce noticeable sebaceous-like swellings on one or both sides of the head, and in extreme cases the abscesses become so large that the turtle is unable to feed or even to withdraw its head into the shell. Other conditions associated with aural abscesses include palpebral edema, lethargy, discharge of inflammatory debris from the mouth or eye socket, and emaciation. The inflammatory debris aggregates in the middle ear, where a caseous material builds up and may be encapsulated by fibrous connective tissue (see color photo 47 in Dodd 2001). In the extreme, this caseous material hardens into an acrylic-like substance. Gram-negative bacteria such as *Citrobacter, Enterobacter, Proteus morganii, P. rettgeri*, and *Pseudomonas* are associated with massive infections, but these bacteria also are part of the normal flora of box turtles (Jackson et al. 1972; Murray 1996).

Whereas most veterinary references discuss the prevalence and etiology of aural abscesses associated with captive box turtles, wild box turtles also have been found with such abscesses. In captivity, aural abscesses are usually attributed to poor husbandry, poor diet, keeping animals at suboptimal temperatures, or a combination of these factors (Boyer 1992; Murray 1996). For wild box turtles or box turtles kept in semi-natural conditions outdoors, the most common suggested causes are insect bites, infectious protozoans, parasitism, or trauma to the buccal cavity with secondary infection (Allard 1935; Dodd 2001; Jackson et al. 1972). Although each of these factors might contribute to the progression of the condition, hypovitaminosis A also is known to lead to abscesses of the middle ear cavity (Boyer 1996; Murray 1996). Interference with Vitamin A metabolism by organochlorine compounds recently has been suggested as leading to aural abscesses in wild *T. carolina* (Holladay et al. 2001).

Between the years 1991 and 2002, we made from one to five visits per year to conduct research on the life history of the Florida Box Turtle (*T. c. bauri*) on Egmont Key, Hillsborough County, Florida. Egmont Key is a long, narrow, north-south trending island located at the entrance of Tampa Bay on Florida's west-central coast. Surveys (N = 35 sampling periods) lasted from three to five days, with from two to five biologists participating in each survey. Box turtles were found in all sections of Egmont Key's approximately 120 ha. As of May 2002, 2477 different box turtles have been recorded, based on 5384 captures. More extensive information on the box turtle study and a physical description of the island are presented elsewhere (Dodd et al. 1994; Dodd 2001).

Throughout the survey, all captured animals were examined in the field for their physical condition. No disease symptoms other than an occasional emaciated turtle were seen until the spring of 1998 when we began to encounter turtles with aural abscesses. In this paper, we describe abscess prevalence and location, field treatment, and recovery based on subsequent recaptures of affected turtles. Further, we relate the appearance of aural abscesses with an unusual weather pattern observed in the winter of 1997–98.

Abscess prevalence and location.—A total of 26 *T. c. bauri* were found with aural abscesses between 1991 and 2002: 14 males, 7 females, and 5 juveniles. The sex ratio generally mirrors that of the overall adult population (1.9 males per female, N = 1776), although the percentage of juveniles with aural abscesses (19%) is less than the percentage of juveniles within the population (27.8%, N = 684 juveniles of 2460 turtles whose sex or life stage could be determined). Turtles with aural abscesses were found as follows: 10 (April 1998), 9 (May 1998), 1 (October 1998), 1 (April 1999), 1 (October 1999), 1 (March 2000), 3 (April 2001). Thus, 73% of the turtles with aural abscesses were found in the early spring of 1998.

The location of the aural abscesses varied, that is, abscesses were not equally distributed. The most common location was on the left side of the head (N = 12: 7 males, 2 females, 3 juveniles), followed by bilateral (N = 9: 4 males, 4 females, 1 juvenile), and finally on the right side of the head (N = 3: 2 males, 1 female). An additional male found basking in direct sunlight had caseous exudate in his mouth, a nasal discharge, and a necrotic rhamphotheca, but no externally observable abscess. We did not record the location of the abscess on one juvenile, although we noted palpebral edema and breathing difficulties. We also noted instances of palpebral edema on three other affected turtles; one adult male with pneumonitis whose abscess extended into the left nostril (this turtle also was very dehydrated); and one turtle whose cyst extended well into the left eustachian tube and exited through the right eye socket.

Turtles with aural abscesses generally were lethargic and appeared unaware of the approach of the observers. Whereas a few

attempted to withdraw their head or limbs into the shell, most did not. Turtles with aural abscesses often were found basking in open locations in the direct sunlight, even during the heat of the day, a behavior that was never observed among box turtles without aural abscesses. Reptiles affected by disease commonly raise the body temperature through basking, a process known as behavioral fever, which aids in fighting bacterial infection (Kluger 1979).

Field treatment.—Because of Egmont Key's relatively isolated location and the logistic difficulties and stress of transporting turtles to the mainland and keeping them under observation after standard veterinary treatment, we decided to treat the animals in the field. One of us (MLG) had 12 years of veterinary surgical experience.

Turtles with aural abscesses were induced to extend their necks as fully as possible. The tympanum was flushed with sterile saline, and a horizontal incision was made across the central bulge of the abscess. In most cases, the caseous material popped out and was removed with small forceps. The flaps of the incision then were opened, and the middle ear cavity was examined internally, using a pen light when necessary, to determine if any inflammatory debris remained. Additional material was gently removed and the cavity repeatedly flushed until all debris was cleansed from the cavity. During removal, we tried to avoid damaging the columella. The cavity required a final flush with sterile saline, and an antimicrobial agent was applied. The amount and consistency of the caseous material removed varied among turtles, and it was sometimes difficult to remove all inflammatory debris without considerable effort.

Before release, close examination of the mouth was conducted to ensure absence of debris from the buccal cavity and areas around the eye sockets. The eustachian tubes connect the middle ear to the oropharynx, and it is through this pathway that pathogens enter the middle ear and that inflammatory debris exits. In nearly all treated turtles, recovery was instantaneous. Where previously the turtle was lethargic and inattentive, it immediately became active, alert, and ready to move off. Allard (1935) also noted a quick recovery among his captive box turtles after similar abscess removal.

Recapture of treated turtles.—Of the 26 turtles treated for aural abscesses, we recaptured 11 whose abscesses had healed and appeared healthy (6 males, 4 females, 1 juvenile); 1 adult male turtle marked in April 1998 was found dead of unknown cause in April 1999. All of these turtles originally had been captured in the spring of 1998. Of the 14 remaining abscess-treated turtles, 1 was first captured in October 1999, 1 was first captured in March 2000, and 3 were first captured in April 2001. The abscess of one of these turtles, a male, was extremely hard indicating a long period of infection. The abscesses of the turtles found in 1999 and 2000, both males, were in the process of rupturing naturally. All of the 9 unaccounted for turtles were last seen in the spring of 1998.

Although treated turtles seemed to recover with no ill effects, the long-term effects of untreated abscesses on turtles are undetermined. It appears that some turtles may recover naturally, because naturally ruptured abscesses were found on several animals. On the other hand, if the abscess hardened into a very hard solid substance and the turtle was unable to feed or withdraw its head over a long period of time, it seems likely that some animals could die from complications resulting from the abscesses. Jackson et al. (1972) reported restructuring of the skull due to massive bacterial infection (based on post mortem examination), and we found several box turtle skulls with bilateral or one-sided bone degeneration, usually affecting the tympanic bulla. However, we cannot directly relate the bone degeneration to the presence of aural abscesses.

Association with unusually wet winter weather.—Because low temperature had been suggested as a possible contributor to abscess development, we examined weather data for the St. Petersburg area, available from the Southeast Regional Climate Center (http://cirrus.dnr.state.sc.us/cgi-bin/sercc/cliMAIN.pl?fl7886). The monthly mean, maximum, and minimum temperatures did not deviate by more than approximately 1°C in any one year from 1991 to 2002 from the monthly mean values from 1948 to 2000. These data suggest that the box turtles on Egmont Key did not experience unusually hot or cold temperatures throughout the study.

When rainfall data were examined, however, one winter season stood out for its excessive rainfall: the winter (November to March) of 1997–98. During this period, Egmont Key received 21.5 cm of rain compared with the normal mean of 5.4 cm. In a normal year, St. Petersburg receives 20.5 cm of rainfall, but in 1998 the area received 28.7 cm, 45.6% of which fell from January to March. From 1991 to 2002, the mean annual rainfall was 19 cm per year (range 15.7–25.2), excluding 1998. In the next closest year in rainfall amount (1995, with 25.2 cm), most rainfall resulted from summer tropical depressions, and winter rainfall was below normal.

Although it might be impossible to determine a cause-effect relationship between the sudden appearance of aural abscesses and an unusually high winter rainfall, such a relationship seems possible. Box turtles are active year-round on Egmont Key (Dodd et al. 1994), but during the winter they spend extended time buried in organic soils to escape cool weather, dry conditions (winter is the dry season in west-central Florida), and periods of low humidity. During this time, heavy rains would result in saturating the shallow organic soils, thus exposing semi-dormant turtles to potentially long periods of direct exposure with wet soils.

Ingestion of contaminated water over an extended period of time results in the colonization of the oropharnyx by infectious bacteria (Murray 1996), so it seems feasible that prolonged exposure to saturated organic soils or the water that accumulates in remnant ditches also might result in bacterial infections through the mouth. Interestingly, all but one of the abscessed turtles was found in the central part of the island, an area crisscrossed by drainage ditches built by the military, and in the Tampa Bay Pilots Association compound, an area with a foul-smelling stagnant water frequented by box turtles. Susceptibility to aural abscesses might be enhanced if the turtle's immune system had been compromised (e.g., by chronic pneumonia; Evans 1983), if the turtle entered dormancy in poor nutrition, or if organochlorines were present in the soil or water which might disrupt Vitamin A metabolism. We suggest that field biologists examine local winter rainfall patterns to determine if the correlation between excessive winter rainfall and aural abscesses that we have observed on Egmont Key is replicated elsewhere.

Acknowledgments.—We thank the Florida Park Service (District 4 Administration) and U.S. Fish and Wildlife Service (Chassahowitzka/Egmont Key National Wildlife Refuges) for issuing permits to work on Egmont Key during 1991–2002, and Robert Baker and Connie Wiesehan and the other park rangers and volunteers who have furnished transport

and lodging facilities during our many stays on the island. Russell Hall reviewed the manuscript and we appreciate suggestions for improvement.

Snout–vent length (SVL) is the most commonly reported measure of linear body size for snakes (Fitch 1987). SVL is correlated with litter or clutch size in many species (Gregory and Larsen 1996; Seigel and Ford 1987) and is an indicator of sexual maturity (Macartney and Gregory 1988) and sometimes of age class (Waye 1999). Measurement of SVL in the field can be difficult for venomous snakes for several reasons: (1) investigator safety must be maintained while restraining the snake, (2) stress and injury to the snake must be minimized, and (3) measurements need to be completed in a timely fashion. Various methods have been developed that deal with each of these constraints to different degrees including physical handling or pinning and stretching (Fitch 1987), anesthesia (Fitch 1987; Hardy and Greene 1999), nooses (Gregory et al. 1989; King and Duvall 1984), and squeeze boxes (Cross 2000; Quinn and Jones 1974).

Quinn and Jones (1974) introduced the 'squeeze box' to estimate the SVL of venomous snakes, which effectively addresses the three concerns stated above. Tongs are used to place the snake into a clear plastic box and a piece of foam or rubber and a clear plastic lid are placed over the snake to hold it in place. The box is inverted and the SVL of the snake is traced for measurement with a map reader, flexible measuring tape, or other device. The procedure is time efficient and relatively safe, and investigators with little experience in handling venomous snakes (e.g., seasonal assistants) show little difficulty in learning its use quickly. The squeeze box thus appears to be an efficient tool to obtain SVLs of snakes, venomous or otherwise.

Despite the apparent merits and widespread use of the squeeze-box method to measure SVLs of snakes, to our knowledge no rigorous analysis of its accuracy and precision has been conducted. Fifty repeated measurements of a single juvenile False Water Cobra (*Hydrodynastes gigas*) showed little variation (Quinn and Jones 1974), but these measurements were not compared to the SVL of the snake measured using alternative methods such as pinning and stretching. Measurements of 10 Cottonmouths (*Agkistrodon piscivorus*) using a modified squeeze box suitable for field studies were compared to the same animals when anaesthetized, and differed by <1 cm (Cross 2000). Here we use data collected during a study of the Northern Pacific Rattlesnake (*Crotalus oreganus*) to address two questions in the use of squeeze boxes: (1) How accurate are length measurements obtained from squeeze boxes compared to those obtained from stretched lengths? (2) How precise are repeated tracings and measurements using squeeze boxes?

We measured SVLs of *C. oreganus* collected during an inventory project (1999–2001) in the vicinity of Kamloops, British Columbia, Canada. Additional data came from animals encountered during the monitoring of a hibernaculum near Vernon, British Columbia (P. T. Gregory and K. W. Larsen, unpubl. data). To measure its snout-vent length, each snake was pinned and grasped behind the head, then stretched along a meter stick. For consistency, one of us (KWL) collected all measurements of SVL. Hereafter we refer to these data as 'standard measurements' of SVL.

After the standard measurement of SVL was obtained for each snake, the animal was transferred to a squeeze box. Our squeeze box consisted of an open-top clear plastic box measuring 42 x 26 x 13 cm. Inside the box were two 5-cm thick pieces of commercial upholstery foam, on top of which fitted a clear lid equipped with a handle that could be grasped by commercial snake tongs. Three tracings were taken for each snake (described below); between tracings the snake was placed on the ground and then picked up and replaced in the squeeze box. We manipulated the position of the animal in the squeeze box only if it was coiled such that a section of its body overlapped another section, e.g., if part of the snake was in a 'figure-eight' position, we would gently prod it until it assumed another position. After the three tracings were

made, we took three measurements of each tracing, using a pocket On Tour Map Measurer™ (Pico Design, Toronto, Ontario).

In total, nine measurements (three tracings, three measurements each) were recorded for each of 21 snakes ranging in SVL from 347–845 mm. We had an additional seven animals for which we had one tracing (with three measurements each). We included these animals in some of our analyses (see below), because they improved the range of sizes of measured snakes. Standard SVL was measured only once for all 28 animals. We determined the sex of each snake by probing for hemipenal pouches or via hemipene extrusion (Blanchard and Finster 1933; Gregory 1983).

TABLE 1. Comparison of different methods used to estimate the snout–vent length (SVL) of rattlesnakes (to nearest mm). Sample size is 21 for all measures. Estimating SVL using a standard approach (stretching animal along a meter stick) provided SVL estimates that were significantly higher than those produced using a squeeze box. Three of the squeeze-box methods involved multiple measurements on the same snake being used to generate a mean value that was used as an estimate of snake SVL. The standard deviation of these multiple measurements also was calculated for each snake, and the average of these standard deviation values is provided.

Method Used to Estimate SVL	Estimated SVL (± SE)	Comparison Standard SVL (paired t-test)	Mean SD
Standard SVL (meter-stick stretch)	696 (± 40.4)	—	—
One tracing, one measurement	603 (± 35.7)	P < 0.001	—
One tracing, three measurements	602 (± 35.9)	P < 0.001	3.9
Three tracings, one measurement each	597 (± 36.2)	P < 0.001	14.4
Three tracings, three measurements each	596 (± 36.3)	P < 0.001	13.6

We used four methods to calculate squeeze-box estimates of SVL, which collectively represent the varying degrees of time and effort that might be invested by an investigator measuring SVL in the field: (1) one tracing, one measurement: one measurement obtained from the single tracing; (2) one tracing, three measurements: mean of three measurements from the single tracing; (3) three tracings, one measurement each: one measurement taken on each of three tracings; (4) three tracings, three measurements each: mean of three tracings used to calculate mean of the three measurements. The grand mean of these three means was used as the datum in analyses.

We compared the estimates of snake SVLs obtained from the four squeeze-box methods to those obtained from the standard method using paired t-tests. Because the latter three methods each produced three initial estimates of SVL per snake (prior to calculation of the grand mean), we were able to calculate the standard deviation (SD) of these measures for each snake. We used the mean SD obtained under each of these squeeze-box methods to assess the variation caused by the inclusion of multiple tracings of the same animal. With only one measurement of standard SVL per snake we could not estimate the variance associated with multiple measurements, however a recent study using a similar method of determining SVL (flexible tape run along the venter of suspended, stretched snakes) found repeated SVL measurements (10 measurements on 20 snakes) to be quite precise as indicated by small deviations of the individual measurements from the mean (mean coefficient of variation = 1.10 ± 0.10%) (Blouin-Demers 2003). Repeated standard SVL measurements in garter snakes also have low variance, even between researchers, once a reasonable amount of experience with the technique has been established (Larsen, unpubl. data).

Estimates of snake SVL provided by the standard method were significantly higher than those provided by any of the four squeeze-box methods (in all cases, $P < 0.001$; Table 1). The average SVL estimates provided by the four squeeze-box methods were similar (± 1.2%), however, variation in the estimates of SVL for each snake expectedly increased as multiple tracings and/or measurements were added (Table 1). Accuracy in estimating SVL (using standard estimates for reference) was not improved by providing additional tracings and/or measurements. A simple regression shows the relationship between measurements of SVL obtained using standard and squeeze-box methods (Fig. 1).

To further illustrate the use of squeeze-box estimates of SVL, we compared a size-frequency histogram developed using squeeze-box data from the one tracing, three measurements calculation (Fig. 2A), with a second histogram constructed using data from the standard method (Fig. 2B). Both frequency distributions have three peaks, however a Kolmogorov-Smirnov two-sample test (Sokal and Rohlf 1969) indicated that the differences in the two distributions were marginally significant ($D_{28,28} = 0.36$; $P = 0.055$).

Our study indicates that using the squeeze box resulted in significantly lower SVL estimates than those obtained using the standard approach irrespective of tracings or measurements. However, because the correlation between squeeze-box estimates

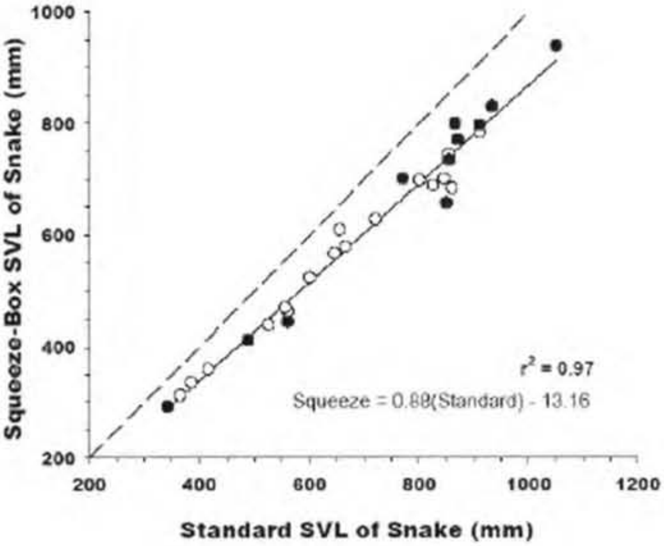

FIG. 1. Relationship between estimates of Northern Pacific Rattlesnake (*Crotalus oreganus*) snout–vent length (SVL) obtained using a squeeze box and values obtained by stretching the snake along a meter stick (standard method; N = 28). Estimates of snake SVL taken using the squeeze box consistently underestimated SVL. Squeeze-box estimates were the average of three measurements from the same tracing of one snake. Data from female snakes are represented by white circles, males by black circles. The dashed line represents a 1:1 relationship.

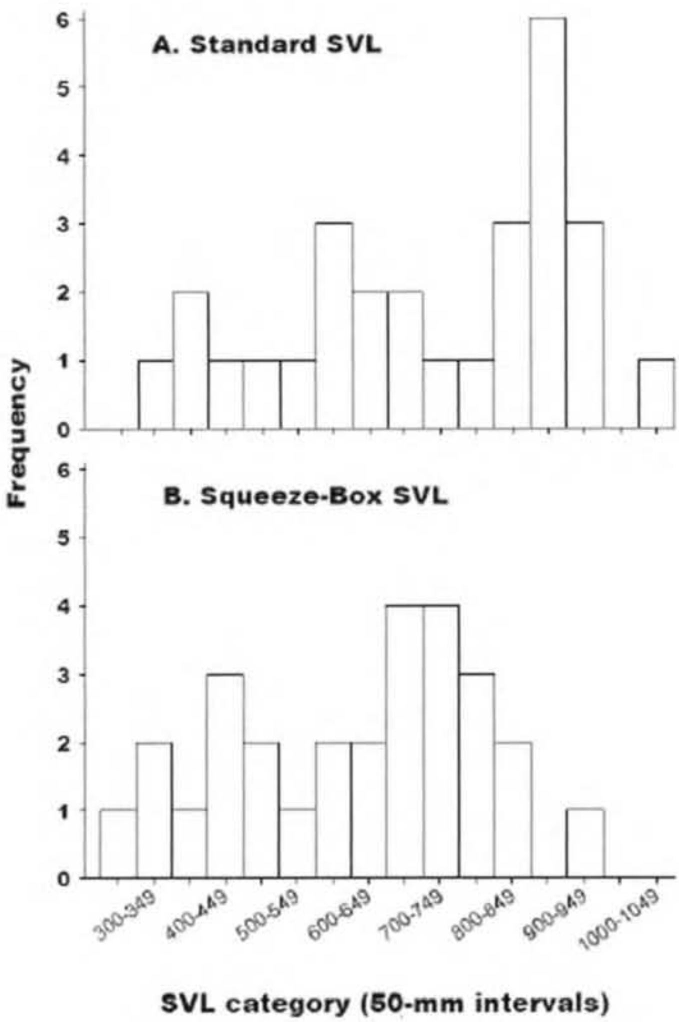

FIG. 2. Differences in size-frequency histograms of Northern Pacific Rattlesnakes (*Crotalus oreganus*) generated from the same animals using A. the standard snout-vent-length (SVL) determined by stretching a snake along a meter stick, and B. using a squeeze box. Each SVL is the mean of three measurements from the same tracing of the same animal.

and standard measurements was strong ($r^2 = 0.97$), it is possible to accurately predict standard SVL from squeeze-box SVLs. Also, because the length estimates obtained from the squeeze box were reasonably precise (i.e., high repeatability), repeated measures of snakes in the squeeze box are unnecessary. The one tracing, three measurements method described here appears to represent a good compromise between maximizing accuracy and precision and minimizing measurement time. Taking three measurements on the same tracing should preclude gross errors in SVL estimation without adding to the stress of the animal. Collecting additional tracings and measurements would increase processing time without improving the accuracy or precision of the estimates.

Different methods exist for measuring the length of snake tracings and may influence accuracy. Quinn and Jones (1974) placed a string along the snake tracing and then measured the string against a meter stick. Cross (2000) used a flexible metric tape for measuring the length of the snake tracing. Regardless of the tool used to record the length of the snake tracing, some error is to be expected. For example, use of a metric tape to measure tracings from tightly coiled animals can be problematic (C. L. Cross, pers. comm.). For these reasons, repeated measurements of each tracing are desirable.

The size of the squeeze box in relation to the snakes being measured also may be an important factor in determining the accuracy of SVL estimates. Squeeze boxes that are large relative to the snakes being studied may be more desirable. In this study there was a trend, albeit weak, of squeeze-box estimates for larger snakes to be less accurate (Fig. 1). This suggests that a larger box might increase the accuracy of measurements, presumably because the snakes would be less contracted during the tracings. The ratio of squeeze-box floor space (cm^2) to maximum snake SVL (mm) was approximately 1:1 in this study. Cross (2000) reported a high degree of accuracy for his squeeze-box estimates of SVL for cottonmouths measured in a squeeze box with a ratio of 1:3.4 (Cross 1998). Relatively large squeeze boxes may be more desirable, but logistics will dictate what size box can be transported in the field. For example, our squeeze box needed to fit into a backpack as it often was carried over long distances.

Given the potential usefulness of squeeze boxes, additional work on the accuracy and precision of this tool is warranted, preferably spanning a variety of taxa. Even the 'standard' method that we used in this study could be examined in more detail: we used data from this method as the benchmark for assessing the validity of length estimates based on squeeze-box measurements, but perhaps an even more effective and less stressful method exists. In general, investigators will need to determine the level of accuracy and precision in SVL measurements required to reach the goals of their respective studies. Detailed studies on life-history trade-offs experienced by snakes may require very accurate SVL data. Conversely, monitoring programs may not need to 'correct' SVL estimates from squeeze boxes, providing the methodology remains constant over time and among researchers.

Acknowledgments.—This study was conducted during the course of a rattlesnake inventory project, funded by the Habitat Conservation Trust Fund of British Columbia. Additional support for the project was provided by Forest Renewal British Columbia, through Aspen Planers Ltd. Research permits were provided by British Columbia Parks, British Columbia Ministry of Environment, Lands and Parks, and the City of Kamloops. Data collection in the field was facilitated by S. Chaput, L. Gomez, P. Gregory, D. Haughland, V. Larsen, and C. Thevarge. C. Cross and A. Savitsky provided us with comparative data on the sizes of squeeze boxes and cottonmouths, and P. Gregory and S. Rollans provided useful comments on a draft of the manuscript. We are grateful for the input of A. Price and an anonymous reviewer.

We examined records from the literature and museum specimens of Ring-necked Snakes (*Diadophis punctatus*) in Utah and conclude that the current conception of the geographic range is inaccurate. Recent field guides (e.g., Cox and Tanner 1995; Stebbins 2003) map a hypothetical range that extends as a narrow, continuous band from the southwest corner of the state through the high-elevation plateaus and mountains of central and northern Utah to southeast Idaho, with a disjunct population in the Deep Creek Mountains of extreme west-central Utah. However, available data do not support this concept of the distribution.

We queried 17 museums, and five of these (BYU, LACM, MVZ, SDSNH, UU; institutional abbreviations follow Leviton et al. 1985) provided records of *Diadophis* in Utah and southeastern Idaho. Localities reported in the literature (e.g., Tanner 1941; Tanner and Banta 1966; Woodbury and Smart 1950) are represented by specimens in museum collections. All records discovered during our searches fall within the Bonneville Basin or the Virgin River drainage (Fig. 1). The elevational range of records appears to be ~1250–2250 m, with the majority falling between ~1500–2000 m. We are not aware of any reports or collections of *Diadophis* in the Wasatch Mountains of north-central Utah. Although the species occurs near Pocatello and Preston in southeastern Idaho (Linder and Fichter 1970; Tanner 1940), the northernmost locality in Utah of which we are aware is at the north end of the Stansbury Mountains (SDSNH 64446), which is about 150 km south of Preston. The range currently is thought to include the Wasatch Mountains between these localities (Cox and Tanner 1995; Stebbins 2003), but we consider the presence of an undetected population to be im-

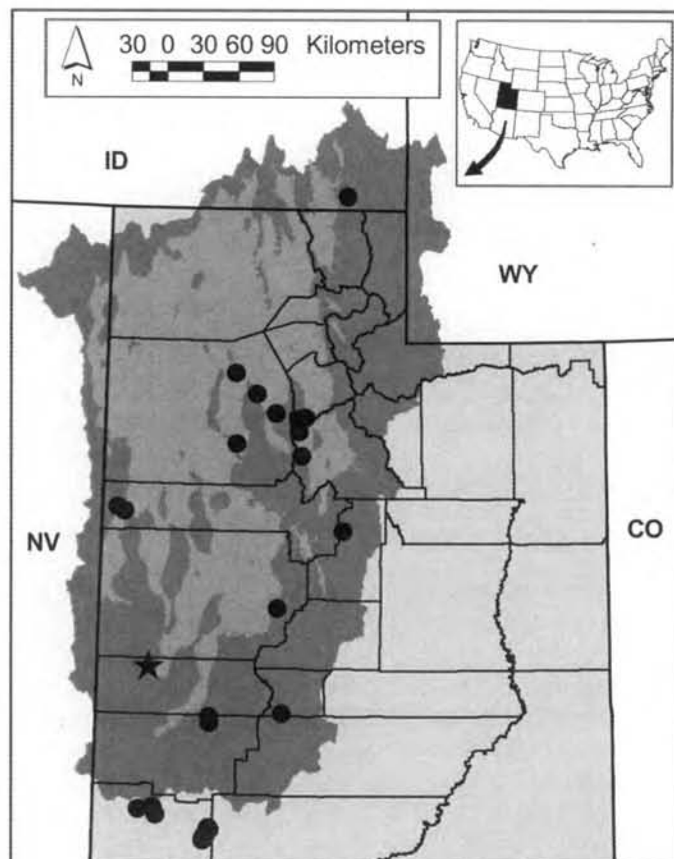

Fig. 1. The distribution of records of *Diadophis punctatus* in Utah and portions of the Bonneville Basin in neighboring states. Circles represent localities from museum specimens or literature; star represents a newly discovered population. Thin black lines within Utah represent county boundaries. The dark shaded area is the Bonneville hydrologic basin (U.S. Geological Survey Great Salt Lake and Escalante Desert-Sevier Lake hydrographic subregions; Steeves and Nebert 1994), and the lighter shaded area is the maximum extent of Lake Bonneville, approximately 14,000 years ago (adapted from Currey et al. 1984).

probable because this is the most urbanized region of Utah and is among the most intensively sampled parts of the state.

Two new records support the concept of a distribution in Utah centered in the Bonneville Basin. Identifications were verified by J. Sites. On 15 May 2001, we found a live female *D. punctatus* (photo specimen BYU 47340) at 2130 h on Hwy 21, 3.2 km west of Wah Wah Summit, Wah Wah Mountains, Beaver Co., Utah, 1849 m elevation. The surrounding vegetation was dominated by grasses (e.g., *Bromus tectorum*, *Oryzopsis hymenoides*) and sparse, small shrubs (e.g., *Chrysothamnus* sp., *Ephedra* sp., and *Artemisia tridentata*). This snake was photographed and released. We found a DOR female (BYU 47353) the following night on the same road, 0.5 km west of Wah Wah Summit, 1955 m elevation. The vegetation at this location was dominated by grasses (especially *B. tectorum*) in a sparse, open stand of juniper (*Juniperus utahensis*) mixed with few small shrubs (mostly *A. tridentata*).

The presence of a population of *Diadophis* in the Wah Wah Mountains suggests that the species may be broadly distributed in the Bonneville Basin (Fig. 1). Areas dominated by juniper and shrub associations are distributed throughout this remote and infrequently visited region. The new records reported herein fill a gap in the known distribution of this species, lying 68 km from the nearest record to the southeast (Minersville, BYU 30021), 120 km from the nearest record to the south (Pine Valley Mountains, BYU 11118), and 130 km from the nearest record to the north (Deep Creek Mountains, UU 1213). Because the species is rarely encountered in this region, the pattern of distribution is difficult to interpret, but the distribution in the basin appears to be associated with the former shoreline of Lake Bonneville (Fig. 1), a large Pleistocene freshwater lake of which the Great Salt Lake is a remnant. It is not apparent, however, if this association arose because suitable habitat is lacking in the presumably unoccupied parts of the basin, because the species failed to colonize suitable habitats that developed after the lake receded approximately 14,000 years ago (Benson et al. 1990), or if the pattern merely reflects sampling effort.

Acknowledgments.—We thank J. Mendelson for help obtaining information and D. Wood, H. Smith, R. Espinoza, and T. Esque for providing invaluable comments on early drafts. We also extend thanks to J. Sites (BYU) for his assistance with specimens. Surveys were funded by a grant from the U.S. Air Force Ogden Air Logistics Center. We are grateful to the following individuals for access to *Diadophis* locality data: J. Sites and W. Skidmore (BYU), K. Beaman and R. Feeney (LACM), D. Wake and J. McGuire (MVZ), B. Hollingsworth and D. Wood (SDSNH), and E. Rickart (UU).

The complexity of anuran reproductive behavior in prolonged breeders has been described in several neotropical species (Bastos and Haddad 1995, 2002; Martins et al. 1998; Pombal et al. 1994). For example, in contrast to explosive breeders, prolonged breeders often have a variety of functionally different vocalizations that are used during the breeding seasons (Bastos and Haddad 1995, 2002; Cardoso and Haddad 1984; Martins and Haddad 1988). Thus, besides advertisement and release calls, some prolonged breeders frequently also emit courtship, encounter, reciprocal, and territorial calls (Bastos and Haddad 2002; Given 1987; Martins and Haddad 1988).

The main reason males compete with each other in breeding aggregations is the scarcity of females (Wells 1977). Males that engage in agonistic interactions sometimes assess the fighting ability of potential opponents, possibly to avoid physical encounters with larger, stronger rivals. One way to do this is to escalate from non-physical to physical interactions, relaying information about body size or motivation before necessarily becoming involved in costly combat. Thus, non-physical displays (e.g., vocal interactions) might be able to resolve conflicts before escalating to physical combat when interacting males differ greatly in size, allowing smaller males to avoid physical encounters with larger opponents (Given 1988; Howard 1978; Parker 1974). Generally, three characteristics determine the outcome of fights: (1) size (Davies and Halliday 1978; Dyson and Passmore 1992; Howard

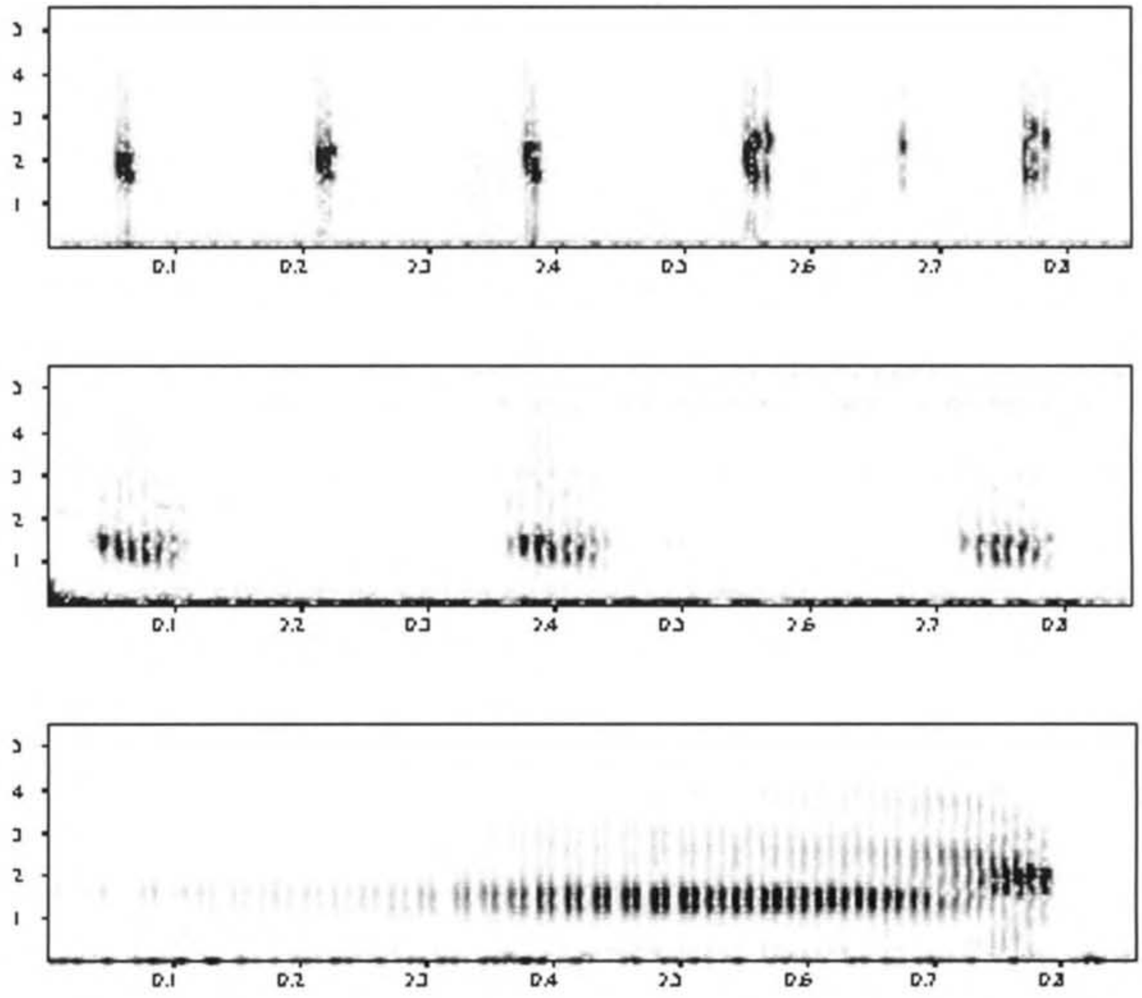

FIG. 1. Sonograms of vocalizations of *Phyllomedusa rohdei*: (A) advertisement call with extra note between the last two notes; (B) territorial call type 1 (T1); (C) territorial call type 2 (T2).

1978), (2) residence (Crump 1988; Given 1988; Pombal et al. 1994), and (3) body condition (Bastos and Haddad 2002).

Our main aim in this paper is to examine the vocal repertoire and aggressive behavior between males of *Phyllomedusa rohdei* Mertens, 1926. Our objectives were to: (1) describe the different call types, (2) describe the social context in which each call type was emitted, (3) describe behavior during aggressive encounters, and (4) determine whether size, residence, or body condition influenced the outcomes of fights.

We studied *P. rohdei* in a temporary pond approximately 170 m^2, located at the edge of a forest at Palmital (22°50'S; 42°27'W), Municipality of Saquarema, State of Rio de Janeiro, southeastern Brazil. The population was monitored from July 1999 to July 2000 for a total of 84 nights (411 h). The visits were monthly when the pond was dry (from July 1999 to November 1999 and from March 2000 to July 2000), and every two weeks when the pond held water (from December 1999 to February 2000). Field observations were conducted usually between 1700 h and 24 h.

Snout–vent length (SVL) was measured to the nearest 0.1 mm with calipers and body mass weighed to the nearest 0.05 g with a Pesola® balance. Individuals were weighed weekly or more frequently when they engaged in aggressive interactions. Males were marked individually by toe clipping (opposable fingers and toes were not clipped).

Focal animal and all occurrence sampling were used for behavioral records (Lehner 1979). A winner was the male that remained in a site after an encounter, while the loser was the one that moved away from the site where the fight occurred. A male was considered a resident if he was the first male to occupy a determined site or if he was already calling or patrolling (see Matos et al. 2000) at the beginning of the focal observations. The time of residence of males was the total number of nights a male spent in a same site.

We recorded the vocalizations with UHER 4000 recorder at a tape speed of 19 cm/s and UHER microphone. Calls were analyzed by the software Avisoft-Sonograph Light 1, version 2.7. The nomenclature of vocalizations follows Duellman and Trueb (1994).

For statistical analysis of results, we used Student's t-test, ANOVA, and Spearman's correlation coefficient (r_s) (Zar 1999). Body condition was estimated by a regression between logs of SVL and mass. We compared slopes of SVL versus mass regressions between winners and losers of aggressive encounters (Zar 1999). Descriptive statistics are given as mean ± SD.

Phyllomedusa rohdei males used vocalizations and physical interactions to defend calling sites. The vocal repertoire included

TABLE 1. Summary of acoustical parameters of the vocalizations of *Phyllomedusa rohdei*. Values are presented as mean ± SD (range) (N).

Characteristics	Advertisement	Calls Types Territorial 1	Territorial 2
Call duration (ms)	553.0 ± 201.0 (178.0–1123.0) (63)	1152.0 ± 718.0 (345.0–3626.0) (18)	841.0 ± 209.0 (574.0–1178.0) (16)
Number of notes	4.3 ± 1.4 (2–7) (63)	4.7 ± 2.4 (2–13) (18)	1
Note duration (ms)	18.0 ± 5.0 (7.0–34.0) (270)	70.0 ± 12.0 (44.0–95.0) (75)	—
Interval between notes (s)	144.0 ± 29.0 (25.0–223.0) (208)	223.0 ± 38.0 (155.0–323.0) (58)	—
Number of pulses	2.3 ± 0.5 (1.0–4.0) (245)	7.8 ± 1.0 (4.0–10.0) (70)	71.2 ± 22.2 (44.0–116.0) (9)
Pulse durations (ms)	7.0 ± 2.0 (3.0–14.0) (549)	6.0 ± 2.0 (3.0–13.0) (420)	7.0 ± 2.0 (3.0–13.0) (303)
Dominant frequency range (kHz)	1.3 ± 0.1 to 2.6 ± 0.2 (1.1–3.2) (62)	0.8 ± 0.1 to 1.9 ± 0.3 (0.7–2.6) (18)	1.2 ± 0.3 to 2.5 ± 0.3 (0.9–3.0) (16)

six types of vocalizations: advertisement call, two territorial calls, two encounter calls, and one release call.

The advertisement call (Fig. 1A, Table 1) was the most common call emitted in breeding aggregations. Males emitted this call at irregular intervals throughout the night. Each call had 1–7 multipulsed notes. One-note calls were emitted frequently at the beginning of the night or in choruses of one or two calling males. Calls greater than three notes sometimes had an extra note of lower intensity between the last two notes (Fig. 1A). In close-range vocal interactions between males of *P. rohdei*, several advertisement calls were emitted in response to another advertisement call or to territorial ones, even when the behavior of both opponents increased in aggressiveness.

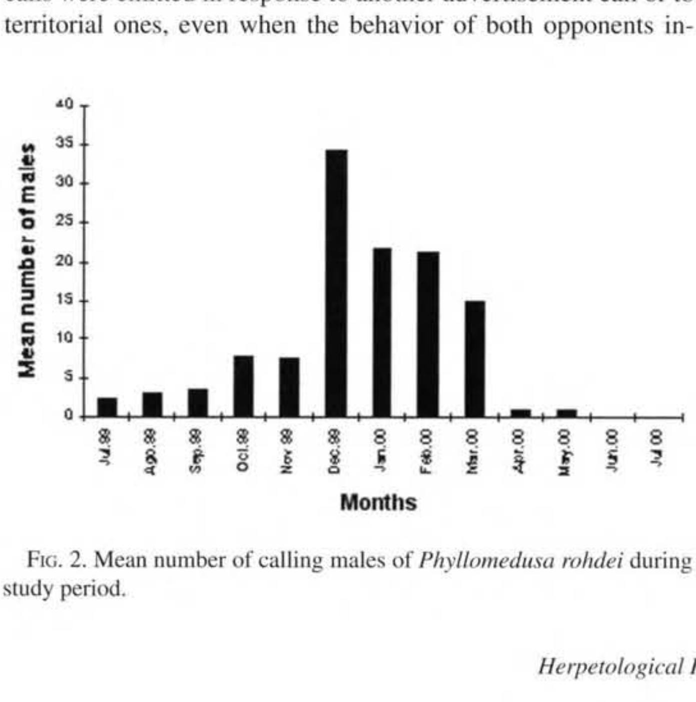

FIG. 2. Mean number of calling males of *Phyllomedusa rohdei* during study period.

Males emitted territorial calls either in response to the advertisement or territorial calls of neighboring males (isolated males did not emit these vocalizations). We observed two types of territorial calls: type 1 (T1) is composed of 2–13 short multipulsed notes (Fig. 1B, Table 1) and type 2 (T2) is a long multipulsed note (Fig. 1C, Table 1). In several agonistic interactions the T1 call was emitted frequently before the T2 by the same male, suggesting an escalated aggressive behavior.

In a few cases, we observed two unusual sounds that were added

TABLE 2. Size difference and resident status of winners of aggressive encounters where opponent differed by more than 3.0 mm in SVL. A positive size difference means that the winner was larger than the loser.

Resident Status	Size difference (mm)
I	9.7
I	7.0
R	6.1
R	4.8
I	4.0
R	3.0
R	-3.3
R	-4.0
R	-4.2
R	-4.4

FIG. 3. Two males of *Phyllomedusa rohdei* in physical combat.

at the end of the territorial calls. Both types consisted of multipulsed notes emitted by resident males during close-range agonistic interactions. Judging by the social context within which they were evoked, these unusual sounds are probably encounter calls.

Finally, a male emitted release calls when trying to dislodge an opponent from his back. These calls are similar to the T1 call with lower intensity.

When neighboring males approached each other and emitted advertisement calls, antiphonal calling between rivals took place. Calls escalated from advertisement calls to both types of territorial calls. One or both males walked under the vegetation searching for the other. Sometimes an individual ceased searching and remained silent or resumed advertisement calling, apparently tolerating its neighbor. However, when males met, vocal interactions continued with two alternative outcomes: (1) one male fled while the other pursued with no fighting, or (2) physical combat occurred. In 15 pursuits observed, the pursuer male was larger (mean ± SD, 39.7 ± 2.1 mm) than the pursued (38.1 ± 1.9 mm; t = 2.20; P = 0.03). However, pursuer and pursued males were not significantly larger (38.9 ± 2.1 mm; N = 30; t = 0.15; P = 0.88) than males that actually fought (38.8 ± 2.5 mm; N = 54). Likewise, the body size differences of males involved in pursuit (2.16 ± 1.93 mm; N = 15) versus those involved in fights (2.65 ± 2.33 mm; N = 27) also were not significantly different (t = -0.69; P = 0.49). Only four pursuer males (27.7%) were smaller than pursued ones. The body differences for all 15 pursuer/pursued pairs were significantly different than zero (F = 18.70; P = 0.0002).

When the pond was dry, we observed only male-male vocal interactions and no physical combat. The distances between calling males before Dec / 99 (pond dry) were larger (154.17 ± 86.40 cm; N = 18) than distances between males after Dec / 99 (pond full) (55.00 ± 37.99 cm; N = 23; t = 4.78; P = 0.00002). More calling males were present when the pond was full than when it was dry (Fig. 2).

During physical combat, each male tried to seize the opponent with his arms and feet (Fig. 3). The uppermost male seized his opponent by the head, neck, or waist, and shook him up and down. The fight finished when the seized male was released by the other or escaped. The loser quickly left and remained in a submissive posture or called from a farther distance than before the interaction, while the winner returned to the original site and resumed calling. Sometimes, winner males oriented toward the loser and shook his body up and down. The duration of fights ranged from 10 s to 30 min and each male had an average of 1.5 fights (range 1–6; N = 36) over the entire breeding season.

In 27 aggressive encounters, the winners (SVL = 39.2 ± 2.1 mm; N = 27; mass = 3.21 ± 0.42 g; N = 23) were not significantly larger (t = 1.23; P = 0.23) nor heavier (t = 1.05; P = 0.30) than losers (SVL = 38.4 ± 2.8; N = 27; mass = 3.08 ± 0.36; N = 23), but the slope of the SVL versus mass regression of winners was significantly higher (b = 1.983 ± 0.43; F = 7.07; P = 0.01) than that of losers (b = 0.519 ± 0.31), indicating that the winners were in better body condition than losers (Fig. 4). When resident and intruder status was determined, 18 of 25 (72%) winners of fights were residents males. The mean time (± SE) of residence of males that fought was 2.2 ± 1.9 nights (range = 1–8; N = 48). Ten fights occurred between males with differences greater than 3.0 mm (Table 2). Smaller males only won these fights when they were residents.

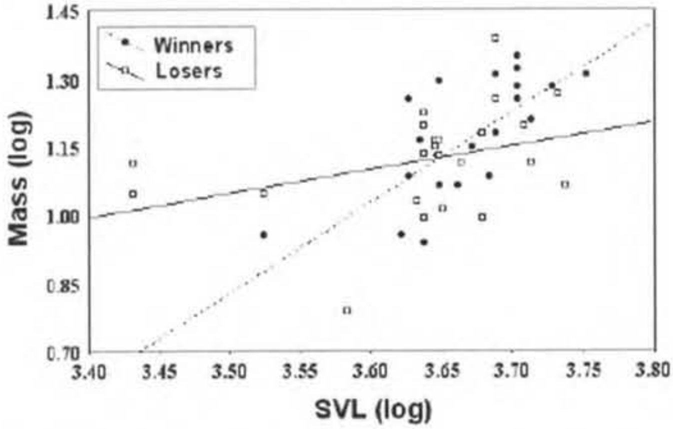

FIG. 4. Linear regression between SVL and mass of winners and losers of aggressive encounters. Variables were log-transformed prior to the analysis.

The complexity of the vocal repertoire in *P. rohdei* reflects social behavior typical of a prolonged breeder (Bastos and Haddad

2002; Cardoso and Haddad 1984; Wells 1977). A secondary function for many vocalization types can be associated with male-male evaluation, especially when aggressive behavior takes place. Threat signals sometimes evolve to enable contestants to assess each other's strength or motivation without resorting to a serious fight (Andersson 1980; Davies and Halliday 1978; Wells 1978). Besides the use of advertisement call, males of *P. rohdei* have two distinct territorial calls and probably two encounter calls. Variable aggressive calls may represent a graded communication system, because these calls may signal the motivational state of the combatants (Given 1987; Martins et al. 1998). In *P. rohdei*, males may be able to assess opponents through acoustic displays, because pursuer males were larger than those pursued and the SVLs of males involved in fights were not different. In other words, if your rival is bigger, run away, and if he is of similar body size, confront him. Nevertheless, differences in size between males engaged in fights (winner/loser pairs) versus pursuer/pursued pairs were not significantly different.

We did not observe physical combat when the pond was dry. This probably can be explained by the greater distance between males when the pond was dry (a mean of 155 cm versus 55 cm when the pond was filled), resulting in fewer close-range male-male encounters. As observed by Sullivan and Hinshaw (1992), low population density was responsible for an apparent lack of direct male-male competition for mates during breeding aggregations of *Hyla versicolor*. When males of *Phyllomedusa hypochondrialis* were distant from each other, fights were not observed (Matos et al. 2000).

In some cases, winners performed visual displays toward losers during aggressive encounters. This behavior was similar to "body jerking" defined by Hödl and Amézquita (2001). However, in body jerking, the movements were performed forward and backward instead of up and down.

Our results showed that residence and body condition influenced the results of 27 aggressive encounters between males of *P. rohdei*. A resident male in better physical condition might have better fighting ability because of larger energy reserves, higher motivational state, or different hormone levels (Wells 1978). Small males only won fights if they were the resident.

Acknowledgments.—We thank Clarissa Canedo, Márcio Martins, Mac F. Given, and Martha L. Crump for their critical reading of and suggestions for the manuscript. We thank F. N. Ramos for field assistance. We are grateful to the CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico), FAPERJ (Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro), and FUJB (Fundação Universitária José Bonifácio) for financial support.

Smilisca baudinii tadpole (UMRC 93-19), 30 mm TL. Belize: Cayo: Vaqueros Creek at San Luis. Illustration by Julian C. Lee.

Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). A single individual of *Tantilla reticulata,* collected from under moss on a tree limb at a height of 6.1 m, is the only documented case of any arboreal activity for this species (Wilson and Meyer 1971. Herpetologica 27:11–40).

In the course of several years of work in the canopy of Costa Rican rainforests, four individual of *T. reticulata* were observed crawling on tree branches at heights of over 27 m. None of these individuals, unfortunately, was vouchered. On 8 March 2003, during a visit to Rara Avis Rainforest Reserve, Heredia Province, Costa Rica (10°18.16'N, 84°02.62'W; 650 m elev.), an adult *T. reticulata* was observed falling from the thatched roof of a building from a height of ~ 5 m. In addition, on 12 March, about 1400 h another *T. reticulata* was observed actively moving about on an epiphyte-covered branch of an emergent canopy tree (*Vantanea barbouri*) at a height of 30.7 m above the ground. Both snakes were collected, photographed (YPM slide collection 1025–26), and released *in situ.* Gregory Watkins-Colwell verified identification of the present snakes.

These observations indicate that *T. reticulata* is more arboreal than previously assumed. The crowns of epiphyte-laden trees in the Rara Avis area provide a microhabitat with a humus layer and moss cover that is often more extensive than that of the local forest floor. It is not clear, however, how these small snakes detect the presence of a suitable habitat far overhead or how they succeed in reaching the canopy, crossing a vertical distance of 30 meters on smooth tree bark.

TRIMORPHODON BISCUTATUS (Western Lyresnake). **PREDATION.** On 7 May 2003, 1250 h, we tracked a male *T. biscutatus,* 810 mm SVL and 153 g, implanted with a 5.2 g radio transmitter in the southern Tortolita Mountains near Oro Valley, Arizona, USA (32°28.201'N, 110°59.015'W). We located the transmitter signal from within 1 m of a *Bubo virginianus* (Great Horned Owl) nest site, which was actively defended by an adult pair of *B. virginianus.* Assuming the snake was dead, we left the site to avoid disturbing the owls further. On 14 May 2003, the owls were not present at the nest, and we found an owl pellet containing the snake's transmitter (Fig. 1) just below the nest. Great Horned Owls are generalist predators, preying on a variety of vertebrates including snakes (Houston et al. 1998. Great Horned Owl. Birds of North America. 372:1–28). We know of no previous records of avian predation on *T. biscutatus.*

FIG. 1. A pellet from *Bubo virginianus* containing a 5.2 g radio-transmitter from *Trimorphodon biscutatus.*

We thank Kirk Setser for his critical reading of this manuscript.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: INDIANA: MARTIN Co: Plaster Creek Seep, SW 1/4, NE 1/4, Sec. 11, T2N, R4W. 8 April 2003. Lee A. Casebere and Michael J. Lodato. Verified by Greg Schneider, University of Michigan Museum of Zoology, UMMZ 229816. First record for county; extends range ca 94 km W of nearest known locality in Jackson County (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Acad. Sci. 404 pp.; Meretsky and Pyles. 2001. Herpetol. Rev. 32:268.) OWEN Co: Jordan Seep, SW 1/4, SW 1/4, Sec. 6, T11N, R4W. 15 April 2003. Lee A. Casebere and Michael J. Lodato. Verified by Greg Schneider, University of Michigan Museum of Zoology, UMMZ 229818. First record for county; extends range ca 37 km SW of nearest known record in Morgan County. (Minton, *op. cit.*) JEFFERSON Co: Chelsea Flatwoods, NE 1/4, NE 1/4, Sec. 33, T3N, R9E. 12 April 2003. Lee A. Casebere. Verified by Greg Schneider, University of Michigan Museum of Zoology, UMMZ 229817, and JEFFERSON Co: Western Wooded Parcel (0.8 km S of the southern boundary of Big Oaks National Wildlife Refuge), NE 1/4, Sec. 31, T5N, R10E. 5 May 2003. Hanover College Herpetology Class. Verified by Joseph R. Robb, U.S. Fish and Wildlife Service. Photo voucher in Illinois Natural History Survey (INHS 2004a–b). First records for county; extends range ca 38 km SE of nearest record in Jackson County (Minton, *op. cit.*; Meretsky and Pyles, *op. cit.*) and ca 16 km S from a recently vouchered (5 April 2003) record in adjacent Ripley County (Skilbred and Meretsky. 2003. Herpetol. Rev. 34:379)

The seep springs at the Martin and Owen county localities support bog-like conditions under or adjacent to hardwood forest canopy. Here the mucky, highly saturated soils are kept wet by perennial groundwater seepage. In contrast, the Jefferson County localities were in hardwood forest on flat, poorly drained, acid, clay soils. Unlike the seep spring sites kept wet year-round by seepage, the flatwoods sites depend on precipitation runoff for the creation of temporary breeding pools. At each of the new localities most of the salamanders encountered were females brooding egg masses, and were well hidden within moss mats, primarily *Thuidium*, on fallen logs and at the base of trees.

These new distributional records are significant in that *Hemidactylium scutatum* is an endangered species in Indiana. It is also noteworthy that all these new localities are from the southern portion of the state, where the species is extremely rare and known only from widely disjunct colonies.

TESTUDINES

APALONE SPINIFERA (Spiny Softshell). USA: ILLINOIS: McDonough Co: S of Macomb on IL 67, 16 km S of intersection of IL 67 and county road 700 N. 6 June 2003. James T. Lamer. INHS photographic record 2004.01. Verified by Chris Phillips, Illinois Natural History Survey. First county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Hat. Hist. Surv. Manual 8, 282 pp.).

Submitted by **JAMES T. LAMER,** Department of Biological Sciences, Western Illinois Universtiy, 1 Universtiy Circle, Macomb, Illinois 61455, USA, and **JOHN K. TUCKER,** Illinois Natural History Survey, 8450 Monclair Ave, Brighton, Illinois 62012, USA.

GOPHERUS POLYPHEMUS (Gopher Tortoise). USA: GEORGIA: Irwin Co.: Sterling Conservation Area, 10 individuals observed in an area begining1.6 km N of Crystal Lake and 1.6 km E of Big Bend Lake and ending 3.14 km N of Crystal Lake and 1.48 km E of Turner Lake. Four occupied burrow locations recorded with global positioning system (31°41'4.83"N, 83°26'42.47"W; 31°41'11.11"N, 83°26'43.22"W; 31°41'37.51"N, 83°26'59.85"W; 31°41'51.84"N, 83°26'40.63"W). 9 June 2003. Christopher R. Wilson. Verified by M. E. McGhee. Georgia Museum of Natural History (GMNH 49219 color photograph). First vouchered and published county record (Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. Special Publication No. 3. Savannah Science Museum. 712 pp). Portions of this population occur on a conservation easement held by North American Land Trust.

Submitted by **CHRISTOPHER R. WILSON**, North American Land Trust / NC Field Office, 196 Arnett Hollow Road, Vilas, North Carolina 28962, USA.

GRAPTEMYS GEOGRAPHICA (Northern Map Turtle). USA: New Jersey: Sussex Co: E side of Delaware River (41°05'34"N, 74°59'28"W), Delaware Water Gap National Recreation Area (DEWA). 13 June 2001. John L. Behler, Christina M. Castellano, and Timothy J. Crockett. Adult female with palpable eggs; maximum carapace and plastron lengths, and mass were 177.3 mm and 160.0 mm, and 605 g, respectively. Photographic voucher deposited in Research and Resource Planning Division files, DEWA, National Park Service (NPS/WCS043-045). Verified by Alvin R. Breisch. Prior to capture, the specimen was observed basking on an exposed, flat rock ca. 9 m away from the shoreline with several common mergansers (*Mergus merganser*) and mallard ducks (*Anas platyrhynchos*). This species' occurrence in the Delaware River, in Bucks County, Pennsylvania, was not detected until recently (Arndt and Potter 1973. J. Herpetol. 7:373–375). Since that time, anecdotal reports (Serrao 2000. The Reptiles and Amphibians of the Poconos and Northeastern Pennsylvania. Llewellyn & McKane Inc., Wilkes-Barre. 49 pp.) suggest that the species' range has extended northward to Northampton Co., Pennsylvania. Between June 2000 and September 2002, more than 50 observations of basking *G. geographica* were recorded in DEWA while surveying turtle riverine habitat. The Delaware River was surveyed from river mile 247 in Sussex (NJ)-Pike (PA) counties at the north end of the park to mile 210 (from the river's mouth) in Warren (NJ)-Monroe (PA) counties near the park's southern boundary. The majority of observations occurred between miles 228 and 218 and in the vicinity of large river islands with sizable sandbanks and adjacent sections of deep water. Basking turtles were typically > 5m from the shoreline on the distal ends of wind-thrown trees, or on exposed logs and flat rocks. The capture location cited above represents a new county record for the species and extends the northward expansion of its range upriver ca. 40 km.

We appreciate the assistance of survey team members Stanley Boder, David Wood, and Sandy Mattfeldt.

Submitted by **JOHN L. BEHLER,** Department of Herpetology, Wildlife Conservation Society, 2300 Southern Boulevard, Bronx, New York 10460-1099, USA (e-mail: jbehler@wcs.org), **CHRISTINA M. CASTELLANO**, Department of Biological Sciences, Fordham University, 441 East Fordham Road, Bronx, New York 10458, USA (e-mail: expansa@aol.com), and **TIMOTHY J. CROCKETT**, Department of Environmental Science and Biology, State University of New York College at Brockport, 350 New Campus Drive, Brockport, New York 14420, USA (e-mail: crocke08@hotmail.com).

PSEUDEMYS RUBRIVENTRIS (Red-bellied Cooter). USA: New Jersey: Warren Co.: Depew Access Road 0.2 km W of Old Mine Road (41°03'31"N, 75°00'17"W), Delaware Water Gap National Recreation Area (DEWA). 4 May 2001. Christina M. Castellano and John L. Behler. Adult female, maximum carapace and plastron lengths were 301 mm and 291 mm, respectively. Photographic voucher deposited in Research and Resource Planning Division files, DEWA, National Park Service (NPS/WCS040-042). Verified by Alvin R. Breisch. Prior to capture, the specimen was observed basking on 24 April 2001 with several *Chrysemys picta* on a small hummock in a 1.5 m deep beaver pond in Miller Farm Marsh 400 m S of its capture site which is located 600 m E of the Delaware River. The distribution of this species in the Delaware River drainage is thought to be restricted to the coastal plain. However, it is likely that viable populations of this species ranged more broadly in the past as it was heavily exploited for eastern food markets in the late 1800s and probably extirpated from its range north of southern New Jersey (Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, 419 pp.). This capture location is ca. 60 km NW of the northernmost locality in the New Jersey Herp Atlas database (Raritan River, vicinity of Somerville, Somerset County; Jason Tesauro, pers. comm.), and is the first report of this species' occurrence above New Jersey's piedmont region.

Submitted by **CHRISTINA M. CASTELLANO**, Department of Biological Sciences, Fordham University, 441 East Fordham Road, Bronx, New York 10458, USA (e-mail: expansa@aol.com),

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: CALIFORNIA: SACRAMENTO CO: 500 m NE of intersection of East Bidwell and Blue Ravine Road (38°39'N, 121°09'W). 22 May 2003. Eric W. Stitt, Dustin Brown, and Peter S. Balfour. Verified by Cecil R. Schwalbe. Slide voucher, University of Arizona Collection of Amphibians and Reptiles (UAZ 55579-PSB). Female, 218 mm midline carapace length, 1515 g. Captured on the bank of a man-made pond ca. 3 m from water's edge, possibly preparing to lay eggs (although no eggs could be felt by palpation). Several other adult *Trachemys* have been observed here, together with the native *Actinemys marmorata*. This subspecies is native to eastern New Mexico through Louisiana, and has been widely introduced throughout the western states (Stebbins 2003. Western Reptiles and Amphibians, Third Edition. Houghton Mifflin Co., New York, NY. 533 pp.). In northern California, this turtle occurs in the Sacramento-San Joaquin Delta, but the status of most populations is unknown (Stebbins, *op. cit.*). Also, although this species is occasionally recorded in local field guides (e.g., The American River Natural History Association. 1993. The Outdoor World of the Sacramento Region: A Local Field Guide. ARNHA, 214 pp.) specific locality data are lacking. Museum records exist from Putah Creek near Davis, Yolo County, California, ca. 60 km ESE of this new locality (CAS 203705–06, 203710). This verifies the turtle's presence in Sacramento County, in the vicinity of Folsom Lake and Lake Natoma.

LACERTILIA

ANOLIS CAROLINENSIS CAROLINENSIS (Northern Green Anole). USA: TEXAS: KERR CO: Kerrville, off Texas Hwy 16, 2145 Sidney Baker Street, at Econo Lodge. 5 March 2004. Z. D. Ramsey and S. F. Barclay. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28279). Verified by Stanley E. Trauth. New county record partially filling hiatus in Edward's Plateau of Hill Country (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. 421 pp.).

Submitted by **ZACHARY D. RAMSEY, STEPANIE F. BARCLAY,** and **CHRIS T. McALLISTER,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA; e-mail: chris.mcallister@tamut.edu.

CNEMIDOPHORUS LONGICAUDA. ARGENTINA: BUENOS AIRES: Partido Monte Hermoso: Monte Hermoso (38°59'S, 61°21' S). 16 February 2002. C. H. F. Perez and P. F. Petracci. Verified by L. J. Avila. Fundación Miguel Lillo Herpetological Collection, San Miguel de Tucumán, Argentina (FML 15208). *Cnemidophorus longicauda* is widely distributed in western Argentina following the Monte phytogeographic province (Cei 1993. Mus. Reg. Sci. Nat. Torino, Mon. XIV:1–949) reaching the Atlantic shores in Buenos Aires, Chubut, and Rio Negro provinces. This represents the easternmost record for this teiid species in Buenos Aires province and extends known range 100 km E of type locality at Bahia Blanca (Williams 1991. CIC 1[4]:1–21; Cei 1993, *op. cit.).* In Buenos Aires province, the species was cited with "doubts" for Partido de Puan, and as "confirmed" for Partido de Villarino and Partido de Bahía Blanca (Williams 1991, *op. cit.)* but without mention of voucher specimens.

The Bahía Blanca record is in the original description but the species was never found again in this locality, probably because of human disturbance of the area. The Monte Hermoso populations probably represent isolated remnants of a more extensive, historical distribution in Buenos Aires province. The lizard was collected in a seashore dune system, outside urban limits of Monte Hermoso City, with typical psammophyllous vegetation and in sympatry with *Liolaemus multimaculatus* and *L. gracilis*.

Submitted by **CRISTIAN HERNAN FULVIO PEREZ**, Agustin Alvarez 1182 A, 8000, Bahía Blanca, Buenos Aires, Argentina (e-mail: liolaemu@criba.edu.ar), and **PABLO FABRICIO PETRACCI**, Patricios 712, 8000, Bahía Blanca, Buenos Aires, Argentina.

GERRHONOTUS LIOCEPHALUS (Texas Alligator Lizard). MEXICO: HIDALGO: 12 km N Metztitlán, 1200 m elev. 16 September 1976. Oscar J. Polaco. Verified by Fernando Mendoza-Quijano. Herpetozoarios Collection of the Escuela Nacional de Ciencias Biológicas (IPN. ENCB-9019). First vouchered record for Hidalgo and a range extension of ca. 253 airline km NW from the nearest record at Cacaloapan, Puebla (Good 1994. Herpetol. Monogr. 8:180–202). Smith (1984. Bull. Maryland Herpetol. Soc. 20:152–158) indicated that *G. liocephalus* occurs in Hidalgo, but gave no corroborating evidence. The subadult female was collected in xerophytic scrub vegetation.

Submitted by **JOSÉ ISMAEL CAMPOS-RODRÍGUEZ** (e-mail: ismaelcampos@msn.com) and **JUAN CARLOS LÓPEZ-VIDAL**, Laboratorio de Cordados Terrestres, Departamento de Zoología, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Apdo. HEMIDACTYLUS GARNOTII (Indo-Pacific Gecko). USA: FLORIDA: MARION CO: Ocala, 611 SE 9th Avenue (29°10'51"N, 82°07'39"W). 2 November 2003. Gerald R. Johnston, Jennifer C. Johnston, and Vaughn A. Newman. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 140123–24). New county record. Two individuals (juvenile 26 mm SVL, adult 42 mm SVL) captured on wall of apartment building. This species has been reported from many counties throughout peninsular Florida (Townsend and Krysko 2003. Florida Sci. 66:204–208).

Submitted by **GERALD R. JOHNSTON**, Department of Natural Sciences, Santa Fe Community College, Gainesville, Florida 32606, USA; and **JENNIFER C. JOHNSTON**, 225 NW 4th Street, High Springs, Florida, 32643, USA. e-mail: jerry.johnston@sfcc.edu.

HEMIDACTYLUS TURCICUS TURCICUS (Mediterranean Gecko). USA: MISSOURI: St. Louis Co.. A hatchling sized (SVL = 21.7 mm) gecko was collected in the offices of Beta Gamma Sigma (BGS) at 125 Weldon Parkway, Maryland Heights, Missouri, 63043, 38°42.460'N, 90°26.487'W. 16 October 2003. Debi Galloway. Verified by A. F. Scott, Austin Peay State University Museum of Zoology, APSU 17482. Employees of BGS continued to observe at least one other hatchling sized individual basking on the outside of their building during warm/sunny days into the last week of October 2003. This is the first documented occurrence of *H. t. turcicus* in Missouri (Johnson 2000. The Amphibians and Reptiles of Missouri. Missouri Department of Conservation, Jefferson City, Missouri. 400 pp.)

Conant and Collins (1998. A Field Guide to Reptiles and Amphibians: Eastern and Central North America, 3rd ed., expanded. Houghton Mifflin, Boston, Massachusetts. 616 pp.) comment on the rapid expansion of *H. t. turcicus* across the southern USA and speculate that it is likely due to humans inadvertently transporting geckos or their egg clutches. The offices of BGS are in the suburbs of St. Louis, Missouri. The large commercial complex is surrounded by residential neighborhoods and retail shopping district. It seems likely that these animals arrived with a shipment of goods to one of the businesses in the commercial complex.

I thank the employees of BGS for reporting the lizard activities they observed, especially my mother-in-law, Donna Binek, for telling me about the lizards running around her new office and Debi Galloway for capturing one.

PRISTIDACTYLUS ACHALENSIS. ARGENTINA: SAN LUIS: Merlo (32°21'S, 65°02'W), 1955 m elev. 2 January 2004. N. E. Salas. Herpetological Collection of Universidad Nacional de Río Cuarto, Ecología, Río Cuarto, Córdoba, Argentina. (UNRC-ECO 781–2). Verified by R. Martori. First province record. Endemic species from Argentina, previously known from Pampa de Achala, departments of San Alberto, Santa Maria, and Punilla, Córdoba (Gallardo 1964. Neotropica 10[33]:132; di Tada et al. 1980. I Reunión Iberoamer. Zool. Vert. 493–512; Avila et al. 2000. *In* Lavilla et al. [eds.], Categorización de los Anfibios y Reptiles de República Argentina, pp. 51–74. Asociación Herpetológica Argentina) and La Paz, department San Javier, Córdoba (Cabrera and Speroni 1986. Hist. Nat. 6[1]:1–12; Cabrera 1996. *In* di Tada and Bucher [eds.], pp. 215–238. Ed. UNRC). Present record extends the known distribution 30 km S from the previously known record.

Submitted by **NANCY E. SALAS** (e-mail: nsalas@exa.unrc.edu.ar), **M. BELEN GIORDANA,** and **ISMAEL E. DI TADA,** Ecología, Departamento de Ciencias Naturales, Facultad de Ciencias Exactas, Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto, Km 601, Ruta N° 36 (X5804BYA) Río Cuarto, Córdoba, Argentina.

SCELOPORUS LUNDELLI (Lundell's Spiny Lizard). MEXICO: TABASCO: 7 km NW Tenosique (17°24'36.3"N, 91°29'9.7"W), ca. 250 m elev. 25 April 2002. Julio César Bolón López. MZFC 14414 (formerly Colección de Amphibios y Reptiles de Tabasco [CART 00321]), CART 00327. Verified by Edmundo Pérez Ramos. First record for Tabasco and extends range ca. 120 km S of Laguna de Términos, Campeche (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Cornell Univ. Press, Ithaca, New York, 500 pp.).

Submitted by **ROSARIO BARRAGÁN-VÁZQUEZ,** Div. Académica de Ciencias Biológicas, Universidad Juárez Autónoma de Tabasco, Km 0.5 Carr. Villahermosa-Cárdenas, Tabasco, Mexico, **LUIS CANSECO MÁRQUEZ,** and **OSCAR FLORES VILLELA**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México (e-mail: ofv@hp.fciencias.unam.mx).

SCELOPORUS UNDULATUS (Eastern Fence Lizard). USA: NEW YORK: Kings Co: Sunset Park. Private property ca. 20 m N of 44th Street between 3rd and 4th Avenues (40°39'02"N, 74°00'36"W). 4–5, 12 September 2002. Jeremy A. Feinberg. Verified by Michael Klemens. American Museum of Natural History (AMNH 153364–68). Locality is the first record from county as well as for the entirety of Long Island, extending the range of this species northeast from the nearest known population in Richmond Co., New York by a distance of ca. 25 km (A. R. Breisch, pers. comm.). Specimens include two hatchlings, one sub-adult, and two adults collected among rocks and wood in the backyard of a private residence. Additional lizards were observed in the yards of adjacent properties. The occurrence of this population within New York City (and on Long Island) is likely the result of an introduction.

Submitted by **JEREMY A. FEINBERG**, United States Fish and Wildlife Service, Brookhaven National Laboratory, Building 120, 81 Cornell Avenue, Upton, New York 11973, USA; e-mail: jerfein@aol.com.

STENOCERCUS FIMBRIATUS (NCN). PERU: JUNÍN: Tarma: Pampa Hermosa (10°59'33.3"S, 75°25'58.0"W, 1540 m elev.). 28 August 2003. Rudolf von May and Edgar Lehr. Museum für Tierkunde Dresden (MTD 45664). Verified by Omar Torres-Carvajal. First record for Departamento de Junín (Avila-Pires 1995. Lizards of Brazilian Amazonia [Reptilia: Squamata]. Zool. Verh. Leiden 299:151–159; Carrillo de Espinoza and Icochea 1995. Publ. Mus. Hist. Nat. UNMSM(A) 49:1–27), and extension of altitudinal distribution. Previously known up to 1050 m on the eastern slopes of the Andes in Peru (Avila-Pires 1995, *op. cit.*). The specimen was caught on a tree branch ca. 1 m above ground in a primary

forest at night.

Submitted by **EDGAR LEHR** (e-mail: edgar.lehr@snsd.smwk.sachsen.de), Staatliche Naturhistorische Sammlungen Dresden, Museum fuer Tierkunde, Königsbruecker Landstrasse 159, 01109 Dresden, Germany, and **RUDOLF VON MAY,** Asociación para la Conservación de la Cuenca Amazónica (ACCA), Calle Cuzco 499, Puerto Maldonado, Madre de Dios, Peru (e-mail: vonmay@terra.com).

TARENTOLA MAURITANICA MAURITANICA (Moorish Gecko). SPAIN: ALMERÍA: Alborán Island (35°56'24"N, 3°02'04"W; in Alborán Sea, the westernmost area of the Mediterranean Sea), 13 m elev., an isolated island 86 km S and 56 km N from the continental coasts of Adra, Almería, Spain and Tres Forcas Cape, Beni-Bu-Gafar, Morocco, respectively. 13 November 2003. Mariano Paracuellos. Dept. of Animal Biology and Ecology, Granada University, Granada, Spain (DBAG-TAMA-30). Verified by Juan M. Pleguezuelos and Xavier Santos. First island record. Two more individuals, belonging to the same species, were observed on the same day, but were not collected. The paucity of herpetofauna on Alborán Island (Ludwig Salvador 1898. Alborán. Heinr. Mercy Sohn, Prag; García and Salas 1984. Jábega 45:76–80; Yus and Cabo 1986. Guía de la naturaleza de la región de Melilla. Exmo. Ayuntamiento de Melilla, Melilla) might be attributed to its small size (7.1 ha) and distance from the mainland. Discovery of three *T. m. mauritanica* on the same day of 2003, after periodic unsuccessful searches since 1994, might indicate a recent colonization probably in association with recent, frequent, transportation of building materials and equipment from the Iberian Peninsula coast, where the species occurs (Hódar 2002. *In* Pleguezuelos et al. [eds.], Atlas y Libro Rojo de los Anfibios y Reptiles de España, pp. 188–190. Dirección General de Conservación de la Naturaleza-AHE, Madrid: for similar cases on other islands, see Pleguezuelos [2002. *In* Pleguezuelos, *op. cit.*, pp. 501–532]).

SERPENTES

ATRACTUS MAJOR (Big Ground Snake). BRAZIL: PARÁ: "Estação Científica Ferreira Penna" (ECFP), between the basins of the Xingu and Tocantins Rivers (01°42'33"S, 51°31'45"W), in the eastern Brazilian Amazon. 11 October 2000. A. L. Prudente. Museu Paraense Emílio Goeldi, Belém, Pará, Brazil, (MEPG 19967). 6 March 2002. R. Vaz. (MEPG 20189). Verified by M. Hoogmoed. First vouchered state record; extends known range ca. 1000 km W from previous records at Manaus, Preto da Eva River, and Presidente Figueiredo municipality (Martins and Oliveira 1993. Zool. Meded. Leiden 67[2]:21–40). This species was cited previously from Pará state without a voucher specimen or locality reference (Vogt and Bernhard 2003. Biodiversidade e Biogeografia de Répteis e Anfíbios da Amazônia, Instituto Amazônia, 40 pp.).

Submitted by **ANA LÚCIA DA COSTA PRUDENTE**, Museu Paraense Emílio Goeldi, Departamento de Zoologia, Setor de Herpetologia, CxP: 399, CEP: 66040-170, Belém, Pará, Brazil (e-mail: prudente@museu-goeldi.br); and **MARIA CRISTINA DOS SANTOS COSTA**, Universidade Federal do Pará, Departamento de Biologia, Cx.P.479, CEP: 66.075-110, Belém, Pará, Brazil (e-mail: mcscosta@museu-goeldi.br).

ATRACTUS RETICULATUS (NCN). URUGUAY: RIVERA: Establecimiento "Trinidad," Campos de COFUSA, Potrero 9 (31°01'55"S, 55°26'41"W). 22 November 2003. R. Maneyro. Colección Zoología Vertebrados, Reptiles, Facultad de Ciencias, Montevideo, (ZVC-R 6237, juvenile female). Captured in a pitfall trap in a forested area (*Pinus*, 6–8 yr old stand) near a small stream. The range of the species includes southern Brazil from São Paulo to São Lourenço do Sul and Argentina, Corrientes and Misiones (Peters and Donoso-Barros 1970. Bull. U.S. Nat. Mus. 297[1]: 33; Cei 1993. Mus. reg. Sci. nat. Torino, Monograf. 14:526; Fernandes 1995. Comun. Mus. Ciênc. Tecnol. PUCRS, Sér. Zool., Porto Alegre 8:37–53; Scrocchi and Giraudo 2002. Smithson. Herpetol. Infor. Serv. 132:11). First country record, extends known distribution 300 km S from São Lourenço do Sul, Rio Grande do Sul, Brazil (Fernandes 1995, *op cit.*). We thank Raul Maneyro for collecting the specimen.

Submitted by **SANTIAGO CARREIRA** (e-mail: carreira@fcien.edu.uy), **MELITTA MENEGHEL**, and **FEDERICO ACHAVAL**, Sección Zoología Vertebrados, Facultad de Ciencias, Iguá 4225, CP 11400, Montevideo, Uruguay.

BOTHROPS BRAZILI (Brazil's Lancehead). ECUADOR: PROVINCIA DE ZAMORA-CHINCHIPE: Bombuscaro River (entrance to the Podocarpus National Park), ca. 04°07'S, 78°58'W, 1000 m elev.). 13 August 1997. R. Tapia. Laboratorio de Anfibios & Reptiles, Universidad San Francisco de Quito & Fundación Herpetológica G. Orcés, Quito (FHGO-USFQ 1639). ECUADOR: PROVINCIA DE MORONA-SANTIAGO: Centro Makuma and surroundings, ca. 02°08'S, 77°42'W, 600 m elev. November 1993–January 2000. D. Holmes, C. Kayap, R. Mangkash, G. Wisurna, et al. (FHGO-USFQ 043 + 16 others). Verified by Jean-Marc Touzet. First locality for Zamora-Chinchipe province, extending its range ca. 200 km SW and 80 km NNW from nearest localities (Río Cusuime, Ecuador and Bagua, Perú; Schatti and Kramer 1993. Rev. Suisse Zool. 100[2]:235–278; Carrillo de Espinosa 1983. Publ. Mus. Hist. Nat. Javier Prado [30]:1–55), representing the westernmost locality of the species and among the highest altitudinal records. Second locality for Morona-Santiago province fills the gap between Pastaza and Morona-Santiago localities, and extends its range 50 km N and 70 km WSW from previous known localities (Schatti and Kramer, *op. cit.*). Despite the species being widely distributed in the Amazon Basin, it is considered rare and was not reported from Ecuador until 1989 (C. Myers *in* Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press. Ithaca, New York. 425 pp.), remaining known from only three localities at Pastaza and Morona-Santiago provinces (Schatti and Kramer, *op. cit.*, Pérez-Santos and Moreno 1991. Mus. Reg. Sci. Nat. Monogr. 11:1–538).

CONIOPHANES LATERITIUS (Stripeless Snake). MEXICO: MORELOS: Municipio de Tlaquiltenango: Sierra de Huautla Biosphere Reserve, 600 m SW of Estación Biológica Sierra de Huautla, on old trail to Huatla (18°27'36.1"N, 99°02'05.2"W), 900 m elev. 20 June 2001. Jorge Chávez-Juárez, Harald Alcaraz-Cruz, and David Valenzuela Galván. Reptile collection, Centro de Educación Ambiental e Investigación Sierra de Huautla - Universidad Autónoma del Estado de Morelos (MOR-REP-145-04-03 No. 46). Verified by Edmundo Pérez Ramos. First record for Sierra de Huautla Biosphere Reserve and southern Morelos, extending its range ca. 60 km S from the nearest collection site at Corredor Biológico Chichinautzin, Morelos (Castro-Franco and Bustos-Zagal 1994. Southwest. Nat. 39:171–213). Juvenile found at 1228 h in rocky terrain adjacent to Lorenzo Vazquez Dam in riparian forest that was surrounded by steep slopes covered by tropical dry forest.

Submitted by **HARALD ALCARAZ-CRUZ** (e-mail: biohac@hotmail.com), **JORGE CHÁVEZ-JUÁREZ** (e-mail: herpetologia@hotmail.com), Facultad de Ciencias Biológicas, Universidad Autónoma del Estado de Morelos (UAEM), Morelos, Mexico; and **DAVID VALENZUELA**, Departamento de Ecología y Conservación de los Recursos Naturales, Centro de Educación Ambiental e Investigación Sierra de Huautla, UAEM, Morelos, Mexico (e-mail: dvalen@buzon.uaem.mx).

CONOPHIS VITTATUS (Striped Road Guarder). MÉXICO: MÉXICO: Municipality of Texcoco: San Salvador Atenco (19° 33' 29" N, 98° 55' 11" W), 2000 m elev. 25 July 1965. F. Aguilar. ENCB 1657. Verified by Fernando Mendoza-Quijano. First record for the state of México (Casas-Andreu *et al.* 1997. Univ. Auntón. Edo. México. Ciencias y Técnicas/32. 201 pp.) and extends the known range 80 km northwest of the closest known locality, 7 mi (11.2 km) south of Cuernavaca, Morelos (MVZ 32258).

Submitted by **NOEMI MATIAS-FERRER** and **SERGIO MURILLO**, Laboratorio de Cordados Terrestres, Departamento de Zoología, Escuela Nacional de Ciencias Biológicas, IPN, Carpio y Plan de Ayala s/n, Ap. Postal 42-186, CP. 11340, Distrito Federal, México; e-mail: noemigecko@hotmail.com.

CORALLUS RUSCHENBERGERII (Ruschenberger Tree Boa; Falsa Mapanare; Dormilona). VENEZUELA: ESTADO TRUJILLO: Municipio Trujillo: Quebrada Valerita, Monay. February 1982. R. Pérez. Colección de Vertebrados de la Universidad de Los Andes, Mérida, Venezuela (CVULA 3299). Verified by Fabián Zerpa. First state record (Roze 1966. La Taxonomía y Zoogeografía de los Ofidios en Venezuela. Univ. Central de Venezuela, Edic. Biblioteca. Caracas, 362 pp.; Lancini and Kornacker 1989. Die Schlangen von Venezuela. Verlag Armitano ed. Caracas, Venezuela, 381 pp.; Henderson.1997. Caribb. J. Science 33 [3–4]: 198–221). *Corallus rushengergerii* is distributed from Costa Rica to northern South America (Colombia, Venezuela and the islands of Margarita, Trinidad and Tobago), according to Henderson (*op. cit.*). The new record is the first intra Andean locality for this relatively widespread species. In Venezuela, this boa snake was previously known north and west of the Guianan shield in Amazonas and Bolívar states, and north of the Orinoco river, in Zulia and Falcón states (Mijares-Urrutia 2000, Herpetofauna of estado Falcón, northwestern Venezuela: a checklist with geographical ecological data, Smithson. Herpetol. Infor. Serv. 123:1–20), Distrito Federal, Carabobo, and Miranda states (Roze 1966, *op. cit.*; Henderson 1997. Carib. J. Sci. 33[3–4]:198–221), Apure, Barinas Bolívar, Delta Amacuro, Guárico, Nueva Esparta, Portuguesa, and Sucre states (Henderson, *op. cit.*; Markezich 2002. Herpetol. Rev. 33:69–74). None of these records predicted this new unsuspected location within the Andes, since all the remaining Colombian and Venezuelan records are from outside the main Cordillera de Los Andes. The new locality record additionally documents the species for the first time from the Lake Maracaibo versant of the Cordillera de Mérida. The closest published geographical records are from near 270 km to the W, in Zulia state, near 250 km to the NE in Falcón state, and ca. 100 km to the E, in Portuguesa state, across the Venezuelan Andean Cordillera de Mérida.

Submitted by **LUIS FELIPE ESQUEDA**, Centro Universitario Herpetológico Forestal y Laboratorio de Biogeografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Mérida 5101, Venezuela (e-mail: adenomera@hotmail.com), and **ENRIQUE LA MARCA**, Laboratorio de Biogeografía, Escuela de Geografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Apartado Postal 116, Mérida 5101-A, Venezuela (e-mail: lamarca1@telcel.net.ve).

CROTALUS ATROX (Western Diamond-backed Rattlesnake). MEXICO: MEXICO: Municipality of Atizapán de Zaragoza: Calocoaya (19°32'N, 99°14'32"W). 13 November 1970. H. Hernández. ENCB 6276. Verified by Fernando Mendoza-Quijano. First record for the state and extends known range ca. 140 km SW of Metztitlán, Hidalgo (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. xii + 425 pp.).

Submitted by **NOEMI MATIAS-FERRER** and **SERGIO MURILLO**, Laboratorio de Cordados Terrestres, Departamento de Zoología, Escuela Nacional de Ciencias Biológicas, IPN, Carpio y Plan de Ayala s/n, Ap. Postal 42-186, CP 11340, Distrito Federal, México; e-mail: noemigecko@hotmail.com.

CROTALUS OREGANUS CONCOLOR (Midget Faded Rattlesnake). USA: ARIZONA: Coconino Co: Labyrinth Canyon. July 1954. Jim Rigg. University of Arizona (UAZ 39830). State record. Originally in the Arizona Sonora Desert Museum collection as ASDM 916. The original ASDM card associated with this

specimen lists "Labyrinth Canyon" in the 'Specific Locality' field, and "Arizona: Coconino Co., Colo. River" under the 'General Locality' field, all in the same handwriting and pen. In a different pen, someone later added "34.5 river miles N. of Lees Ferry," apparently in reference to the confluence of Labyrinth Canyon and the Colorado River. An American Museum of Natural History specimen (AMNH 75814) collected in adjacent Utah from a "sandbar on the Colorado River about 40 mi upstream from Lee's Ferry, Arizona" by R. Zeller on 19 June 1956 and is also *concolor*. The collection locality of AMNH 75814 appears to lie ca. 6–7 km upstream of UAZ 39830 in Glen Canyon. Both of these specimens agree with all scutulation, color, and pattern characters as described in the original description (Woodbury 1929. Bull. Univ. Utah 20:3–4) and in Gloyd (1940. The Rattlesnakes, Genera *Sistrurus* and *Crotalus*. Chicago Acad. Sci. Spec. Publ. 4). Counts of dorsal scale rows at midbody, ventrals, subcaudals, supralabials, infralabials, body blotches, and tail blotches all fall within the ranges (and usually near the means) presented for *concolor* by Gloyd (*op. cit.*). Both specimens are nearly identical to published portraits of the form in systematic or authoritative works (e.g., Plate 25 in Gloyd, *op. cit.* and Fig. 2:66 in Klauber 1972. Rattlesnakes. Their Habits, Life Histories, and Influence on Mankind. 2 Vol. 2nd ed. University of California Press, Berkeley and Los Angeles), and neither shows any morphological evidence of intergradation with adjacent forms.

Although most specimens from San Juan County, Utah appear to be *Crotalus viridis* based on mtDNA haplotype, a single specimen from "27.8 km E of Halls Crossing Marina" on the Colorado River had a *concolor* haplotype (Douglas et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 11–50. Eagle Mountain Publishing, Eagle Mountain, Utah.). Gloyd (*op. cit.*) illustrates the southern terminus of the range of *concolor* in the general vicinity of Halls Crossing. We believe that the *concolor* lineage probably occupied much of Cataract Canyon, and portions of Glen Canyon as far downstream as its confluence with Labyrinth Canyon. Further downstream, specimens from Antelope Island and Wahweap Marina agree morphologically and by mtDNA haplotype with *abyssus* (Douglas et al., *op. cit.* and pers. comm.). The collection localities of both UAZ 39830 and AMNH 75814 in Glen Canyon have been flooded since the late 1960s by Powell Reservoir. It remains to be seen if this form is extant in the side canyons of Glen Canyon (Arizona and Utah).

Submitted by **THOMAS C. BRENNAN** and **ANDREW T. HOLYCROSS**, School of Life Sciences and Museum, Arizona State University, Tempe, Arizona 85287-4501, USA.

CROTALUS SCUTULATUS (Mojave Rattlesnake). MEXICO: MEXICO: Municipality of Ixtapaluca: Cerro del Pino (19°20'N, 99°55'18"W). 2500 m elev. 13 July 1967. R. Cruz C. ENCB 6276. Verified by Fernando Mendoza-Quijano. This confirms the presence of this species in the state of México (Casas-Andreu et al. 1997. Univ. Auntón. Edo. México. Ciencias y Técnicas/32. 201 pp.). The previous record is a fossil specimen from Zumpango (Brattstrom 1955. Bull. South. California Acad. Sci. 54:1–4).

Submitted by **NOEMI MATIAS-FERRER** and **SERGIO MURILLO**, Laboratorio de Cordados Terrestres, Departamento de Zoología, Escuela Nacional de Ciencias Biológicas, IPN, Carpio y Plan de Ayala s/n, Ap. Postal 42-186, CP. 11340, Distrito Federal, México; e-mail: noemigecko@hotmail.com.

DENDROASPIS POLYLEPIS (Black Mamba). CAMEROON: Adamaoua Province: Nyassar (ca. 50 km NE of Ngaoundéré: 7°32'20"N, 14°02'38"E, 800 m elev.). Elevated soudanian savanna. 15 August 2001. Matthew LeBreton and Laurent Chirio. Verified by Ivan Ineich. MNHN 2002.921 (Field No. 4582X). First confirmed record for this species in Cameroon. A number of authors have indicated the uncertainty of the occurrence of this species in Cameroon (Håkansson and Madsen 1983. J. Herpetol. 17:186–189; Rasmussen 1994. Nord. herpetol. Forening 37:61–65; Chippaux 2001. Les serpentes d'Afrique occidentale et centrale. IRD Paris 292 pp.) despite the presence of at least one record of possible sighting there (Stark 1986. J. Herpetol. Assoc. Africa 32:31, without voucher specimens).

Submitted by **MATTHEW LEBRETON**, CAMHERP Project C/- Cameroon Biodiversity Conservation Society, BP 3055 Messa Yaoundé, Cameroon (present address: Johns Hopkins Cameroon Program, BP 7039, Yaounde, Cameroon), and **LAURENT CHIRIO,** 14 Rue des Roses, 06130 Grasse, France.

DRYMOLUBER BRAZILI. BRAZIL: BAHIA: Municipality of João Dourado, District of Gruta dos Brejões (11°00'S, 41°25'W). 1 August 2002–31 August 2003. Collector unknown. Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia (MZUESC 3815). Verified by Miguel Trefaut Rodrigues. Previously known only from southcentral Brazil (Nogueira 2001. Herpetol. Rev. 32:285; Peters and Orejas-Miranda 1986, Bull. U.S. Nat. Mus. 297:100). First record for northeastern Brazil; extends range ca. 1000 km NE of Brasília municipality (Nogueira, *op. cit.*), the previous northernmost limit for the species.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz – UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil; e-mail: lachesis@uesc.br.

FARANCIA ABACURA ABACURA (Eastern Mudsnake). USA: FLORIDA: UNION CO: 0.8 km N of State Road 100 on County Road 231 (29°55'55"N, 82°19'41"W), 105 meters elevation, 2248 hours. 6 June 2002. Michael E. Welker. Verified by Kenneth L. Krysko. Florida Museum of Natural History (FLMNH), Gainesville, Florida, USA (UF 133816). New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second edition. Windward Publishing, Miami, Florida. 176 pp.). This specimen was found DOR.

Submitted by **MICHAEL E. WELKER**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA; e-mail: herpconservation69@yahoo.com.

GEOPHIS BLANCHARDI (Blanchard's Earth Snake). MÉXICO: OAXACA: Municipality of San Bernardino: Sierra Mazateca, Puerto Soledad. (18°09.499'N, 96°59.981'W), 2510 m elev. 10 June 1993. Luis Canseco Márquez and Alejandro Ramos Torres. MZFC 13303 (regurgitated by a *Thamnophis godmani*). 1 km SW Puerto Soledad, 2240 m elev. 13 November 1993. MZFC 13304. Both verified by Edmundo Pérez Ramos. First records for Oaxaca and extends the range ca. 69 km (airline) SE of Acultzingo, Veracruz (Downs 1967, Misc. Publ. Mus. Zool., University of Michigan 131:1–193). Both specimens were found in cloud forest.

Submitted by **LUIS CANSECO MÁRQUEZ, ALEJANDRO RAMOS TORRES,** and **OSCAR FLORES VILLELA**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México; e-mail: ofv@hp.fciencias.unam.mx.

HETERODON PLATIRHINOS (Eastern Hog-nosed Snake). USA: FLORIDA: Dixie Co: 0.03 km E of County Road 351 on County Road 353 (29°41'37"N 83°01'52"W). 1 November 2003. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 141054). New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second edition. Windward Publishing, Miami, Florida. 176 pp.). This specimen was found on the shoulder of the road in the grass.

Submitted by **MICHAEL E. WELKER** and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA; e-mail: herpconservation69@yahoo.com

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). USA: FLORIDA: Lafayette Co: 1.4 km N of Dixie Co. line on County Road 357 (29°51'18"N 83°14'40"W), 2021 hours. 13 September 2003. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 141055 photographic voucher). New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second edition. Windward Publishing, Miami, Florida. 176 pp.). Female found crossing the road. It is currently maintained in captivity and will be deposited at FLMNH upon death.

Submitted by **MICHAEL E. WELKER** and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA; e-mail: herpconservation69@yahoo.com.

NINIA ATRATA (Hallowell's Earth Snake; Culebra de Tierra; Viejita). VENEZUELA: ESTADO BARINAS: Municipio Bolívar: Barinitas, Parque Moromoy. E. La Marca, D. Briceño and F. Ayaach. 22 March 1997. Colección de Anfibios y Reptiles, Laboratorio de Biogeografía, Universidad de Los Andes, Mérida, Venezuela (ULABG 4334). First state record. Second record from a Venezuelan Andean locality, fills the gap between a Táchira state record located 220 km to the SW at Burgua River (Roze 1966. La Taxonomía y Zoogeografía de los Ofidios en Venezuela. Univ. Central de Venezuela, Edic. Biblioteca. Caracas, p. 106) and a Portuguesa state record at Mesa de Cavacas, 75 km to the NE (Markezich 2002. Herpetol Rev. 33:69–74), corroborating its presence in the lowland versant of the Andean Cordillera de Mérida (Lancini and Kornacker 1989. Die Schlangen von Venezuela. Verlag Armitano ed. Caracas, Venezuela, 381 pp.). ESTADO BOLÍVAR: Municipio Caroní: Las Piñas, Guri. Ciudad Guayana. 150 m elev. 28 January 1985. Grupo de Ecología Animal. Colección de Vertebrados de la Universidad de Los Andes, Mérida, Venezuela (CVULA 3696). First state record and first Venezuelan locality south of the Orinoco River (Roze 1966, *op. cit.*; Rivas and Oliveros 1997, Memoria Soc. Cienc. Nat. La Salle 94:36–43). This specimen documents a range extension of 300 km S from the closest northern Venezuelan locality at Cueva del Guácharo in Monagas State (Roze 1966, op. cit.; Gorzula and Señaris 1999 "1998". Contribution to the Herpetofauna of the Venezuelan Guayana I. A Data Base. Scientia Guaianae 8:i-xviii + 1–269 + 32 pls.) and brings the species into the Venezuelan Guayanan shield area, making this taxon part of its Herpetofauna, a fact that was previously explicitly denied (Gorzula and Señaris, op. cit.: 174).

Submitted by **ENRIQUE LA MARCA**, Laboratorio de Biogeografía, Escuela de Geografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Apartado Postal 116, Mérida 5101-A, Venezuela (e-mail: lamarca1@telcel.net.ve), **LUIS FELIPE ESQUEDA**, Centro Universitario Herpetológico Forestal y Laboratorio de Biogeografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Mérida 5101, Venezuela (e-mail: adenomera@hotmail.com); **JESÚS MANZANILLA**, Museo del Instituto de Zoología Agrícola, Universidad Central de Venezuela, Maracay, Aragua, Venezuela (e-mail: jmanzanilla@mncn.csic.es).

OPHEODRYS AESTIVUS AESTIVUS (Northern Rough Greensnake). USA: FLORIDA: Hamilton Co: 3.9 km W of County Road 135 on County Road 6 (30°30'37"N, 82°5001"W), 107 m elev. 30 May 2003. 0.1 km W of County Road 135 on County Road 6 (30°30'05"N, 82°44'17"W), 108 m elev. 19 June 2003. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 137230–231. New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second edition. Windward Publishing, Miami, Florida. 176 pp.). The first specimen was found alive on the road and is represented by a photograph. The second specimen was found DOR and is represented by a preserved specimen.

Submitted by **MICHAEL E. WELKER** and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA; e-mail: herpconservation69@yahoo.com.

OPHEODRYS VERNALIS BLANCHARDI (Smooth Green Snake). USA: SOUTH DAKOTA: Marshall Co: vegetable garden at home-site in Sacred Hills Circle Community, ca. 1.6 km NW Veblen (45°52'42.8"N; 97°18'30.8"W). 22 September 2003. Laurs Bryan James Williams. Verified by Stanlee Miller. Campbell Museum, Clemson University (CUSC 2169). County record. Previously reported in adjacent Roberts County. (Fishbeck and Underhill 1959. Proc. South Dakota Acad. Sci. 38:107–113).

Submitted by **LAURS BRYAN JAMES WILLIAMS** and **STEVEN G. PLATT**, Department of Math and Science, Oglala Lakota College, P.O. Box 490, Kyle, South Dakota 57752-0490, USA.

PITUOPHIS LINEATICOLLIS LINEATICOLLIS (Middle American Gopher Snake). MÉXICO: JALISCO: Rancho San Francisco, ca. 1.5 km NE Tapalpa, 2134 m elev. 21 June 1983. Jonathan A. Campbell, William W. Lamar, and David M. Hillis. UTA R-25959. Verified by Eric N. Smith. New state record and extends the range ca. 150 km SW from the nearest record at Dos Aguas, Michoacán (Duellman 1961, Univ. Kansas. Publ. Mus. Nat. Hist. 15:1–148).

Submitted by **PAULINO PONCE-CAMPOS**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México; (e-mail: poncecp@hotmail.com), and **PAUL C. USTACH**,

Department of Biology, The University of Texas at Arlington, Arlington, Texas 76019-0498, USA.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORIDA: HILLSBOROUGH Co.: Tampa, 12801 N 52 Street (28°3.748'N, 82°23.826'W). 29 November 2003. K. C. Hennessy and M. Michalak. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida (UF 140726). Found within leaf litter. New county record (Wilson and Porras 1983. Univ. Kansas Mus. Nat. Hist., Spec. Publ. 9, 89 pp.).

Submitted by **KELLY C. HENNESSY** and **MARTIN MICHALAK**, Florida Museum of Natural History, Division of Ichthyology, University of Florida, Gainesville, Florida 32611, USA; e-mail: kelly3@ufl.edu.

SIBYNOMORPHUS TURGIDUS (Slug-eating Snake). ARGENTINA: CÓRDOBA: DEPARTAMENTO MARCOS JUÁREZ: Marcos Juárez city (32°42'S, 62°06'W). 6 December 2001. Herpetological collection, Fundación Miguel Lillo, Tucumán, Argentina (FML 12522). Verified by G. Scrocchi. Species known from northern and central Argentina, Bolivia, Paraguay, south of Mato Grosso in Brazil, and Uruguay (Franco 1994. O gênero *Sibynomorphus* Fitzinger 1843, no Brasil [Colubridae; Xenodontinae; Dipsadini], Dissertação de Mestrado em Zoologia, Pontifícia Universidade Católica do Rio Grande do Sul, Brazil, 148 pp.; Achával and Olmos 1997. Anfibios y reptiles del Uruguay, Montevideo, Uruguay, 128 pp.; Giraudo and Scrocchi 2002. Smithson. Herpetol. Infor. Serv. 132, 53 pp.). Second record for the province (205 km S airline from previous citation: Cabrera and Merlini 1989. Iheringia, Ser. Zool. 69:151–153), extends known distribution in Argentina 180 km (airline) SW from previous southernmost record (Scrocchi et al. 1993. Rev. Brasil. Biol. 53[2]:197–208).

Submitted by **GERARDO C. LEYNAUD** and **RAQUEL SILMARA CERVANTES**, Centro de Zoología Aplicada, Universidad Nacional de Córdoba, Casilla de Correo 122, Córdoba (5000), Argentina; e-mail: gleynaud@efn.uncor.edu.

SISTRURUS MILIARIUS BARBOURI (Dusky Pygmy Rattlesnake). USA: FLORIDA: HAMILTON Co: 5.2 km N of US 41 on County Road 135 (30°25'58"N, 82°41'08"W), 108 m elev. 1.1 km W of County Road 135 on County Road 6 (30°29'07"N, 82°45'79"W). 13 October 2002. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 137117, 137116). New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second edition. Windward Publishing, Miami, Florida, 176 pp.).

Submitted by **MICHAEL E. WELKER** and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA; e-mail: herpconservation69@yahoo.com.

STORERIA DEKAYI WRIGHTORUM (Midland Brownsnake). USA: ARKANSAS: SEVIER Co: 8.0 km W Falls Chapel off Frog Level Rd. 28 February 2004. Z. D. Ramsey. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 28278). Verified by Stanley E. Trauth. New county record partially filling hiatus in extreme southwestern Arkansas (Trauth et al. *In press*. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville). *Storeria dekayi* has also been reported previously from adjacent McCurtain Co., Oklahoma (Webb 1970. Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, Oklahoma, 370 pp.; Secor and Carpenter 1984. Oklahoma Herp. Soc. Spec. Publ. 1:1–57; Sam Noble Oklahoma Museum of Natural History Database of Reptiles [http://www.snomnh3.ou.edu/db/reptiles/]; Oklahoma Biological Survey's Distribution of Oklahoma Amphibians and Reptiles by Recorded Sightings, DOKARRS [http://www.biosurvey.ou.edu/dokadesc.html]).

Amphibian and Reptile Distribution Records for Louisiana

JEFF BOUNDY
Louisiana Department of Wildlife and Fisheries, P.O. Box 98000
Baton Rouge, Louisiana 70898-9000, USA
e-mail: boundy_jj@wlf.state.la.us

The following records add to a comprehensive summary of the occurrence of amphibians and reptiles within Louisiana, based on specimens housed in the Louisiana State University Museum of Natural Science (LSUMZ). Receipt of new records is largely due to the accession into LSUMZ of the collections formerly housed at the University of Louisiana at Lafayette and Southeastern Louisiana University, uncatalogued material from Northwestern State University, as well as recent collecting efforts by several individuals credited within the following accounts. All records are new for their respective parishes, based on Dundee and Rossman (1989), unless otherwise noted.

Caudata

Ambystoma maculatum (Spotted Salamander). SABINE PARISH: Bayou Toro at LA 392. 16 August 1973. Jack Deshotels, Philip St. Romain, Mark Staton. LSUMZ 60050.

Amphiuma tridactylum (Three-toed Amphiuma). SAINT JOHN THE BAPTIST PARISH: Frenier Rd, 200 m W of Lake Pontchartrain. 15 April 1988. Cliff Fontenot. LSUMZ 58689.

Hemidactylium scutatum (Four-toed Salamander). EAST FELICIANA PARISH: Idilwild LSU Experimental Farm, SC boundary on Gross Rd, 2.2 km E of Idilwild Rd. 1 February 2001. Jeff Boundy. LSUMZ 82992.

Necturus louisianensis (Red River Mudpuppy). NATCHITOCHES PARISH: Kisatchie Bayou approx. 9 km NE of Kisatchie. 9 April 1977. Tom Hardaway. LSUMZ 62955.

Anura

Eleutherodactylus planirostris (Greenhouse Frog). LAFAYETTE PARISH: Memory Ln, Lafayette. 30 July 2000. David Patton. LSUMZ 81452. PLAQUEMINES PARISH: LA 23, E side of Boothville. 7 September 2000. Jeff Boundy. LSUMZ 81461. Latter record extends range of this introduced species to near mouth of Mississippi River.

Gastrophryne carolinensis (Eastern Narrow-mouthed Toad). RED RIVER PARISH: 14.4 km E of Coushatta on LA 155. 12 May 1973. N. Loftin. LSUMZ 85447–449.

Hyla avivoca (Bird-voiced Treefrog). WEST FELICIANA PARISH: LA 964, 3.6 km SE of US 60. 28 April 1966. William Fullilove. LSUMZ 14756.

Hyla chrysoscelis (Cope's Gray Treefrog). ST. JAMES PARISH: 1.0 km N of Grand Point. 20 February 2003. Jeff Boundy. LSUMZ 86113–114.

Hyla femoralis (Pine Woods Treefrog). LIVINGSTON PARISH: LA 22, 3.6 km W of Killian. 26 July 1996. Steve Karsen. LSUMZ 57774, 57775. Also from Livingston Parish: LSUMZ 87350.

Hyla squirella (Squirrel Treefrog). ST. JAMES PARISH: 1.0 km N of Grand Point. 19 April 2003. Jeff and Scot Boundy. LSUMZ 87155.

Pseudacris crucifer (Spring Peeper). WINN PARISH: 4.8 km S of Winnfield. 4 April 1971. Collector unknown. LSUMZ 85163.

Rana palustris (Pickerel Frog). BEAUREGARD PARISH: LA 111, 3.6 km N of US 190. 8 April 1967. Larry D. Wilson. EAST FELICIANA PARISH: LA 10, 11.3 km W of Clinton. 27 April 1969. J. Moore. LSUMZ 69957. VERNON PARISH: LA 111, 2.9 km S of LA 392. 19 February 1966. Larry D. Wilson. LSUMZ 42249.

Rana sphenocephala (Southern Leopard Frog). WINN PARISH: 3.6 km E of Brewton's Mill. 1 July 1974. B. Stewart. LSUMZ 70332. An additional record from Winn Parish: LSUMZ 70333.

Scaphiopus hurterii (Hurter's Spadefoot). RED RIVER PARISH: 14.4 km E of Coushatta on LA 155. 12 May 1973. N. Loftin. LSUMZ 84987. A supporting record from Red River Parish: LSUMZ 85318.

Crocodilia

Alligator mississipiensis (American Alligator). RED RIVER PARISH: Red River near Coushatta. 15 September 1964. John H. Champion. LSUMZ 14567.

Testudines

Apalone spinifera (Spiny Softshell). VERMILION PARISH: LA 70, 1.8 km E of LA 92. 28 April 1975. Lou Wahlen. LSUMZ 75144.

Chelydra serpentina (Snapping Turtle). BIENVILLE PARISH: Friendship Lake on LA 4. 15 April 1969. G. Alvarez, Douglas Rossman, D. Ramsden. LSUMZ 32820. A supporting record from Bienville Parish: LSUMZ 86121. ST. JOHN THE BAPTIST PARISH: Edgard. 3 February 1969. C. G. Boerne. LSUMZ 32823.

Deirochelys reticularia (Chicken Turtle). ALLEN PARISH: US 190, 13.9 km WNW of Kinder. 14 April 1968. Douglas A. Rossman, Nita J. Rossman. LSUMZ 19202.

Graptemys ouachitensis (Ouachita Map Turtle). EAST BATON ROUGE PARISH: Baton Rouge. 11 May 1963. Brent Nickog. LSUMZ 34026. TENSAS PARISH: Louisiana side of Rodney Lake. 18 November 1995. Steve Shively. LSUMZ 57267.

Malaclemys terrapin (Diamond-backed Terrapin). LAFOURCHE PARISH: Bayou Ferblanc, approx. 5.4 km NW of Jefferson Parish line. 15 August 1970. Jim Bishop, Bo Blackman. LSUMZ 29569. VERMILION PARISH: University of Southwestern Louisiana Biological Field Station. 18 February 1961. C. R. Norden. LSUMZ 74149.

Pseudemys concinna (River Cooter). EAST FELICIANA PARISH: Amite River at LA 10. 3 June 1971. Patricia Kimmich Blaney. LSUMZ 41103. GRANT PARISH: 3.6 km S of Georgetown. 21 April 1950. J. Pharis. LSUMZ 1661. LAFAYETTE PARISH: D. S. Young Farm, Kaliste Saloom Rd 2.2 km W of Flanders Rd. 5 May 1973. Kenneth M. Fahey. LSUMZ 74179, 74180.

Terrapene carolina (Eastern Box Turtle). VERMILION PARISH: 43 km S of Kaplan. 19 April 1964. Larry D. Wilson. LSUMZ 32916. RED RIVER PARISH: 3.2 km S of Coushatta on LA 1. 25 April 1973. Tom Damico. LSUMZ 86169. 20.8 km E of Coushatta. 12 May 1973. N. Loftin. LSUMZ 86170.

Lacertilia

Anolis sagrei (Brown Anole). EAST BATON ROUGE PARISH: Louisiana Nursery near Bluebonnet Blvd and Perkins Rd, Baton Rouge. 9 October 2001. Ryan Chabarria. LSUMZ 83818. Adults and juveniles persisted at this site through mid-2002, but it could not be determined whether they represented a reproducing population or repetitious importations via plants (R. Chabarria, pers. comm.). LAFAYETTE PARISH: Lafayette Nursery, Lafayette. 1975. No collector. LSUMZ 71668. ORLEANS PARISH: jct of Decatur and Esplanade, New Orleans. 24 September 2000. Frank Burbrink. LSUMZ 81976. *Anolis sagrei* was found in substantial numbers in the LaPlace area, Saint John the Baptist Parish at various times during the 1980s and early 1990s, supposedly introduced accidentally by reptile dealers, but populations never persisted, evidently due to winter mortality (L. Prima, D. Vicknair, pers. comm.; no vouchers).

Eumeces anthracinus (Coal Skink). ALLEN PARISH: 20 km S of jct of LA 26 and LA 1156. 9 April 1973. Marion Moore. LSUMZ 71698. BEAUREGARD PARISH: Smyrna Rd, 24 km E of DeRidder. 3 April 1980. Mike Harbison. LSUMZ 85891.

Eumeces fasciatus (Common Five-lined Skink). ASCENSION PARISH: NW Intersection of I-10 and LA 22, Sorrento. 5 March 1998. Jeff Boundy. LSUMZ 59491. Bluff Swamp directly E of Bayou Braud. 17 March 1999. Jeff Boundy, Steve Shively. LSUMZ 80890. An additional specimen form ASCENSION PARISH: LSUMZ 86480. BIENVILLE PARISH: 4.8 km S of Castor. 20 June 1976. John Bruza. LSUMZ 85895.

Eumeces laticeps (Broad-headed Skink). SAINT JOHN THE BAPTIST PARISH: 0.5 mi S of US 61, W of Evangeline Rd, LaPlace. 1 October 1997. Jeff Boundy. LSUMZ 58581.

Hemidactylus turcicus (Mediterranean House Gecko). PLAQUEMINES PARISH: Belle Chasse Naval Air Station. 20 April 1998. Jeff Boundy, Steve Karsen. LSUMZ 59610. ST. CHARLES PARISH: Bonne Carre Spillway, W side, 0.8 km S of US 61. 14 February 2001. Jeff Boundy, Adam Leache. LSUMZ 83029–030. TANGIPAHOA PARISH: Southeastern Louisiana University Campus. 23 March 1987. C. Knight. LSUMZ 59591. Also from Tangipahoa LSUMZ 59592. WEST BATON ROUGE PARISH: LA 76, 0.9 km E of LA 417. 18 January 1963. M. J. Fouquette. LSUMZ 75397.

Ophisaurus attenuatus (Slender Glass Lizard). ACADIA PARISH: Egan. 5 February 1966. E. M. Trumps. LSUMZ 73501. EVANGELINE PARISH: LA 10, 7.6 km SE of Beaver. 28 June 1965. Jack Fouquette, Jim Delahoussaye. LSUMZ 73497. LAFAYETTE PARISH: LA 92 bridge E of Maurice city limits. 26 April 1975. Michael Courville. LSUMZ 73511. NATCHITOCHES PARISH: Red Dirt Wildlife Management Area, jct of Longleaf Trail and Bluff Camp Rd. 2 June 1995. Darrel O'Quinn. LSUMZ 57077. Also from Natchitoches Parish: LSUMZ 57639, 80998, 83492, 84660, 85797. ST. TAMMANY PARISH: Lake Ramsey Rd, 0.5 km E of Lake Ramsey Subdivision. 16 October 1998. Steve Karsen, Brian Horn. LSUMZ 80718. AVOYELLES PARISH: road between Marksville and Alexandria. 9 April 1959. Harold Cleveland. LSUMZ 86417.

Sceloporus consobrinus (Prairie Lizard). AVOYELLES PARISH: 1.7 km W of Cottonport on Bayou Rouge. 15 April 1965. Glenda Tarver. LSUMZ 75562–75564. EVANGELINE PARISH: Clearwater. 15 November 1958. G. M. Stokes. LSUMZ 75530. Additional specimens from Evangeline Parish: LSUMZ 75535, 75539–40, 75545.

Serpentes

Agkistrodon contortrix (Copperhead). ACADIA PARISH: near Eunice. 15 November 1961. McClendon. LSUMZ 82238. Additional speciemens from Acadia Parish: LSUMZ 82239–243.

Carphophis amoenus (Eastern Worm Snake). ASCENSION PARISH: near Gonzales. September 1966. Collector unknown. LSUMZ 18218.

Cemophora coccinea (Scarletsnake). CALCASIEU PARISH: LA 12, 18 km NE of Starks. 19 June 1971. Jim Roberts. LSUMZ 75938.

Crotalus horridus (Timber Rattlesnake). NATCHITOCHES PARISH: Longleaf Trail, 1.8 km E of Kisatchie Bayou. 21 April 1990. Douglas A. Rossman. LSUMZ 49582. Additional vouchers from Natchitoches Parish include: LSUMZ 58462, 83711, 84967. RAPIDES PARISH: LA 8 at Sharp. 23 April 1997. Theron Magers. LSUMZ 58475. Additional specimens from Rapides Parish: LSUMZ 78817–18.

Diadophis punctatus (Ring-necked Snake). ASCENSION PARISH: 5.4 km S of Kleinpeter. 23 February 1962. Laurence Binford, Burt Monroe Jr. LSUMZ 11969–70. Additional vouchers from Ascension Parish: LSUMZ 16688, 22956, 29341, 58257, 80895.

Farancia abacura (Red-bellied Mudsnake). ACADIA PARISH: Interstate 10, 9 km E of Jennings. 11 May 1975. James McLean. LSUMZ 28594. Additional vouchers from Acadia Parish. LSUMZ 75906, 59063.

Heterodon platirhinos (Eastern Hog-nosed Snake). ASCENSION PARISH: LA 44, 12.6 km NE of Donaldsonville. 1 July 1966. Larry D. Wilson. LSUMZ 43565.

Lampropeltis calligaster (Yellow-bellied Kingsnake). GRANT PARISH: US 71 between Colfax and Montgomery. 2 May 1997. Theron Magers. LSUMZ 58514.

Lampropeltis getula (Common Kingsnake). ASCENSION PARISH: near Belle Helene Plantation. 8 May 1965. E. Breaux. LSUMZ 23761. Additional vouchers from Ascension Parish: LSUMZ 47464, 59492, 86472.

Nerodia erythrogaster (Plain-bellied Watersnake). ST. BERNARD PARISH: LA 46, 3.6 km E of St. Bernard. 26 April 1998. Steve Karsen. LSUMZ 59622.

Opheodrys aestivus (Rough Greensnake). SABINE PARISH: 1.6 km E of Many on LA 6. 23 September 1986. Jodi Werfal. LSUMZ 86308.

Regina rigida (Glossy Crayfish Snake). ASCENSION PARISH: Bluff Swamp. 8 December 1982. C. Yates. LSUMZ 41510. Additional specimens from Ascension Parish LSUMZ 42161, 42174.

Storeria dekayi (Dekay's Brownsnake). ASSUMPTION PARISH: LA 308, 9.6 km SE of Napoleonville Courthouse. 28 January 1973. James D. Rives III. LSUMZ 77903.

Storeria occipitomaculata (Red-bellied Snake). ASCENSION PARISH: Gonzales. 15 October 1998. Frank Marabella. LSUMZ 80971. EVANGELINE PARISH: approximately 6.5 km N of Basile. 5 April 1969. Paul Meier. LSUMZ 77955. WINN PARISH: 11.2 km E of

Atlanta. 21 April 1962. Keith A. Arnold. LSUMZ 12254. Also from Winn Parish LSUMZ 23902.

Thamnophis proximus (Western Ribbonsnake). WINN PARISH: LA 501, 2.3 km N of Calvin. 26 April 1969. R. Munz. LSUMZ 23861.

Thamnophis sirtalis (Common Gartersnake). ASSUMPTION PARISH: 8 km S of Napoleonville on LA 401. 15 April 1968. A. J. Kern. LSUMZ 79299. LAFOURCHE PARISH: Kraemer. 5 April 1975. Collector unknown. LSUMZ 47312. NATCHITOCHES PARISH: near Robeline. No date. Theron Magers. LSUMZ 85826, 86342–43.

Virginia striatula (Rough Earthsnake). EVANGELINE PARISH: Basile. 10 April 1969. Mark Meier. LSUMZ 81527. Additional records from Evangeline Parish: LSUMZ 81528, 81529. 81530. VERMILION PARISH: Vermilion Bayou 1.8 km S of Abbeville. 15 May 1971. Cecil LeBlanc. LSUMZ 81561–62.

Virginia valeriae (Smooth Earthsnake). GRANT PARISH: Pollock. April 1996. Kristi Wharton. LSUMZ 57754-57758. WEST FELICIANA PARISH: Butler's Mansion, 3.6 km N of St. Francisville. 16 March 1963. Douglas H. Morse. LSUMZ 17901.

Acknowledgments.—I thank James Jackson and Robert Jaeger (ULL), and Brian Crother and Richard Seigel (SLU) for presenting their estimable collections to the LSUMZ, and Jonathan Akin for donations from NSU. I also wish to thank Jim McGuire and Tom Devitt for taking the time to confirm the identification of specimens.

Chamilpa 62210, Cuernavaca, Morelos, México

As a part of the project entitled Herpetofauna of the Sierra de Huautla and Biological Corredor Chichinautzin in central Mexico, we collected six species previously unknown in Morelos and documented range extensions for three others. The new records were found in the Sierra de Huautla in southern Morelos, an extensive natural protected area of tropical dry forest and oak forest. The specimens were captured and preserved using the standard methods proposed by Simmons (1987). The specimens were deposited in the herpetological collection of the Universidad Autónoma del Estado de Morelos (EBUM). All specimen identifications were verified by Fausto Mendez de la Cruz.

Testudines

Apalone spinifera spinifera (Eastern Spiny Softshell). An adult female (EBUM 2898), found in the Río Amacuzac near the Las Huertas spa, Municipality of Tlaquiltenango (18°33'50"N, 99°33'50" W), 947 m elev., 17 October 1999. The first vouchered record for Morelos. An individual was previously observed in Cruz Pintada pond, Sierra de Huautla, but not reported by Castro-Franco and Bustos (1994). These turtles were introduced to Morelos as pets released near rivers.

Lacertilia

Cnemidophorus communis (= *Aspidoscelis communis*) (Colima Giant Whiptail). One subadult (EBUM 2355) captured in Ajuchitlán (18°28'30"N, 99°0'6"W), Municipality Tlaqiltenango 1053 m elev., 25 October 1997. Previously known from the coastal lowlands of Colima, Jalisco, and Michoacán, from the plateau region of Colima, and the low valleys of the Sierra de Coalcoman and Tepalcatepec Valley, Michoacán (Duellman and Zweifel 1962).

Cnemidophorus lineattissima (= *Aspidoscelis lineattissima*) (Twelve-lined Whiptail). One female (EBUM 2435) collected in Chimalacatlán (18°23'13"N, 99°7'20"W), Municipality Taquiltenango, 760 m elev., 8 February 1998. This species was known to occur in lowlands, northwestward from the Río Balsas Basin in Tepalcatepec Valley, Michoacán and Nayarit (Duellman and Wellman 1960).

Phrynosoma asio (Giant Horned Lizard). Two adult males (EBUM 3421–22), collected 2 km S of the pyramids archaeological zone Chimalacatlán, Municipality of Tlaquiltenango, 1065 m elev., 8 February 1998. Previously reported by Smith and Taylor (1950) from Colima through coastal Michoacán, Guerrero, Oaxaca, Chiapas, and Mexcala, Guerrero along the Río Balsas.

Sceloporus utiformis (Largescale Spiny Lizard). An adult male (EBUM 2373), collected 4 km S of Tilzapotla (18°27'7"N, 99°16'6"W) in Puente de Ixtla county, in a tropical dry forest, "Los Cocos" canyon, bordering the state of Guerrero. Three adult females (EBUM 2371–72, 2374) were collected on "Cerro Frio" (18°27'7"N; 99°16'8"W) 1 km S of Tilzapotla in oak forest. Recorded previously by Smith and Taylor (1950) near Colima. They described the distribution as being on Pacific slopes from southern Sinaloa to western Guerrero, extending inland about 125 miles in the southern part of the range. Previously known in Sinaloa, Nayarit, Jalisco, Colima, Michoacán, Guerrero (Smith and Taylor 1950; Ramírez-Bautista 1994).

Serpentes

Agkistrodon bilineatus bilineatus (Mexican Cantil). One male (EBUM 3422) was collected SE of Coaxitlán, Municipality of Tlaquiltenango (18°26'39"N, 99°10'21"W) under fallen leaves in a dry forest. Previously known in Morelos from Progreso (18°53'0"N, 99°10'0"W), Jiutepec 9 km E of Cuernavaca City (Davis and Smith 1953).

Coniophanes lateritius (Stripeless Snake). An adult male (EBUM 3420) captured in Rancho la Herradura, Ahuatepec, 7 km NE of Cuernavaca (18°57'30"N, 99°12'10"W) 1850 m elev., 7 August 1988, and another observed in the Sierra de Huautla in southern

Morelos, 15 April 2002. Previously known in Morelos from Huajintlán, south of Puente de Ixtla (Smith and Taylor 1945).

Ficimia publia (Blotched Hook-nosed Snake). One male (EBUM 2446) was found dead on the road 2 km S of Chimalacatlán (18°26'21"N, 99°06'22"W) Municipality of Tlaquiltenango, in tropical dry forest. Smith and Smith (1976) reported *F. publia*, *F. ruspatur*, and *F. olivacea* near Cuernavaca, Morelos, where we have frequently observed *Pseudoficimia frontalis* but not specimens of *Ficimia*. Hardy (1972) believed that records of *Ficimia* from Cuernavaca were misidentified specimens of *P. frontalis*. Castro-Franco and Bustos (1994) supported Hardy (1972) and commented that *Ficimia* does not occur in the Cuernavaca area. Thus, our record of *F. publia* from Chimalacatlán is the first confirmed report of this species from Morelos.

Micrurus laticollaris (Balsan Coral Snake). Several records extend the range of this species within Morelos. EBUM 2390, a female collected near Cruz Pintada pond, Sierra de Huautla, Municipality of Tlaquiltenango (18°33'39"N, 99°01'26"W) at 1050 m elev., 25 October 1997; EBUM 055 and 502, females captured in El Texcal, Municipality of Jiutepec (18°50'00"N, 99°10'00"W) at 1380 m elev., 23 November 1978; EBUM 500, 503 in Cuautla (18°50'45"N, 98°56'30"W); EBUM 501, 2 km E of Palpan, Municipality of Miacatlán (18°51'0"N, 99°25'0"W); EBUM 504, 6 km N of Michapa pond, Coatlán del Rio (18°39'45"N, 99°29'0"W). All specimens were found in dry forest. Previously recorded from Cuernavaca, Morelos (Smith and Taylor 1945) and Progreso, Jiutepec (Davis and Smith 1953).

Acknowledgments.—This research was supported by Comisión Nacional para el Manejo y Uso de la Biodiversidad (CONABIO), agreement FB468/L319/97.

Multi-authored volumes always strike me as potentially iffy propositions. When the chapters are carefully edited and united by a common conceptual theme, the result can be a well-integrated body of work that makes a major collective contribution to its field. Too often, however, such volumes are simply collections of loosely related chapters that could just as easily have been published separately in disparate outlets. *Biology of the Vipers* does have a common theme, but it is a taxon rather than a conceptual area, and the chapters that comprise the book cover the map in terms of subject matter. Thus, the likely audience is clear (and fairly narrow): snake biologists. I study snakes, so I naturally was drawn to *Biology of the Vipers*, and, although I cannot offer unqualified praise, I found my time reading it to have been quite well spent.

Biology of the Vipers originated in an international conference held in May 2000 in Marielund, Sweden. The book also serves as a companion and, in some ways, successor to an earlier multi-authored volume, edited by Campbell and Brodie (1992), on pitvipers. The two books are identical in size and format and *Biology of the Vipers* even has a foreword by Campbell and Brodie, cementing this line of succession. The main difference is the increase in breadth of the newer work to include all vipers. Appropriately enough for this wider embrace and for the location where the conference was held, the picture on the dust jacket, by William B. Montgomery, is of the adder, *Vipera berus*. The authors comprise a virtual who's-who of students of viper biology, both seasoned veterans and younger practitioners. Coverage is biased towards New World and European taxa, with relatively little on Asiatic species and no chapters on African species. This presumably reflects bias both in where research is being done and in who participated in the conference.

Biology of the Vipers is a big book, 580 pages long, with 35

chapters under four section headings: Systematics, Taxonomy, and Phylogeography; Behavior, Ecology, Natural History, and Evolution; Physiology and Reproductive Biology; and Conservation. Chapters range in type from reviews to more particular studies on a single species. Several chapters discuss work that is in its early stages; one such chapter essentially amounts to a detailed research proposal. The biggest section, with 21 chapters, is the second one on Ecology. It seems to be a bit of a catch-all for papers that did not fit obviously under any of the other headings. This section in fact easily could have been subdivided into more cohesive units. Several papers on envenomation and predatory behavior (Cundall; Hayes et al.; Kardong and Smith; Stiles et al.) are clearly closely related, but they do not even appear close to one another in the apparently random order of chapters in this section. The section on Conservation is the shortest, with only two chapters. The book concludes with 16 pages of fine color plates showing most (or all? —I didn't count) of the many species mentioned in the text, complete with notes on natural history in the captions.

The most cohesive section, it strikes me, is the first one on Systematics. Not only were there common themes here, but the various authors seemed to be aware of each other's chapters and made appropriate cross-references. I am neither a molecular biologist nor a systematist, but I found these chapters, while not a gripping read, a very useful overview and update (among the latter being the genus *Daboia*, which was new to me). Because of the snake fauna in the region where I live, I was especially interested in the chapter by Douglas et al. on the phylogeography of the Western Rattlesnake (*Crotalus viridis*) complex, which has been the subject of much analysis, including some recent papers. Douglas et al.'s conclusions are strongly shaped by their support for the phylogenetic species concept, which in turn leads to some important differences with other workers in taxonomic assignments. Thus, the Northern Pacific Rattlesnake (*Crotalus oreganus*) is either a separate species (Douglas et al.) or a subspecies of a more widely distributed Western Rattlesnake (Ashton and de Queiroz 2001). This is an important debate, but I think that it could be conducted with a little more temperate language: Douglas et al.'s dismissal of the conclusions of others as "gratuitous" is impolite, at best.

As an ecologist, I found myself on more familiar and comfortable ground in the long section on behavior, ecology, etc. However, I also found the papers in this section to be very uneven in quality. Some, though, were models of their kind. For example, the chapter by Hayes et al. on factors influencing venom expenditure was a well-written, comprehensive, and critical review that also incorporated some new data. I was especially interested in the differences between defensive and predatory strikes, which I must admit I had thought about only fleetingly in the past. Most important, though, Hayes et al. (p. 225) encourage researchers to widen their view beyond just snakes in order to put envenomation by snakes into a broader evolutionary context. I say "Amen" to that sentiment. Other authors in this book also make clear links between their work and general theory (e.g., Douglas et al., Höggren and Tegelström), but this kind of connection is lacking in some chapters. In fact, I was reminded in places of an article by Bonnet et al. (2002), on taxonomic chauvinism in publishing, in which they complained that papers on ectothermic vertebrates in "high-impact" ecological journals had to be framed more conceptually than those on endotherms. Bonnet et al. (2002) supported this argument with data showing, among other things, that the first mention of the study organism appeared significantly later in papers on ectotherms. I'm not so sure that this is a bad thing, and not just for papers on ectotherms.

A number of other chapters in the Ecology section were highlights for me. Greene et al. combine detailed natural history observations, experiments, and phylogenetic analysis in revealing strong evidence for postpartum (or post-hatching) parental behavior in many vipers. One of the points that intrigued me in this chapter was the extreme care that the authors took to minimize disturbance when they observed wild rattlesnakes. This can only be a good thing, but I was left wondering: "Are rattlesnakes really that sensitive?" In my experience, rattlesnakes are among the most watchable of snakes in the wild, an observation supported by the details presented in this chapter, which would be difficult to obtain for many (most?) other kinds of snakes. Sealy, in a chapter in the later section on Conservation, also touches on this point. He observes, for example, that Timber Rattlesnakes (*Crotalus horridus*) in woodlands can be approached very closely without any apparent response unless directly disturbed. Snakes away from cover, by contrast, exhibit various defensive behaviors when approached. Thus, context matters.

Greene et al. also go to some lengths to reduce the effects of handling on short- or long-term behavior, taking all measurements from their snakes with the animal under anesthesia. But how important are these effects? Are they necessarily worse than the grogginess accompanying recovery from anesthesia? No doubt there is variation among taxa, but I doubt that the requirement for anesthesia is a general one for handling snakes. For example, I have watched garter snakes return to foraging and catching food within seconds of release, just after I have stretched, weighed, and palpated them for food. Greene et al. raise an important issue, though, and one that I've thought about a lot, but also one that is difficult or impossible to test. How can we study any animal, even just watching it, without potentially disturbing it? How can we know that what we are seeing is natural?

Another chapter that caught my attention was that by Mori et al. on the subtropical Hime-Habu (*Ovophis okinavensis*), a low-temperature binge-feeder on breeding ranid frogs. This chapter reminded me of the Rubber Boa (*Charina bottae*), which is sometimes active at night at quite low temperatures that are below its apparent preferred body temperature (Dorcas and Peterson 1998). The Hime-Habu shows little evidence of physiological adaptation to low temperature; for example, it cannot digest food quickly at low temperatures (although it can retain it for digestion). Apparently, activity on cool nights and low-temperature feeding are seen in some other Asiatic vipers: in their chapter, Orlov et al. note such behavior in at least two other species of *Ovophis* and in *Azemiops*.

The chapter by Orlov et al. is in fact one of the real services that this book provides, one that would be unlikely to be duplicated in a journal article. Orlov et al. summarize distribution, taxonomy, and natural history information for 21 species and subspecies of little-known Asiatic viperids. Coupled with the color plates at the back of the book, this chapter provides the beginnings of what could be a very useful field guide.

The third section (Physiology) of *Biology of the Vipers* consists of six chapters, of which three struck me as particularly interest-

ing, albeit in different ways. Almeida-Santos and Salomão report on reproduction in tropical vipers, discussing, among other things, uterine muscular twisting (apparently similar in function to the copulatory plug of natricines), evidence for parthenogenesis (surely molecular tools could be used to settle this question), and the occurrence of inter-sex females in *Bothrops insularis*. In another chapter, Beaupre uses an individually based physiological simulation to model growth and reproduction in rattlesnakes. The model itself is informative enough, but so are Beaupre's introductory admission to having seen the error of his ways about the utility of models and his good advice about the role that models can play in the development of hypotheses to test experimentally. He provides plenty of such ideas. Bonnet et al., in the following chapter, argue for applying the complementary approaches of physiological experiment and mark-recapture population analysis to determine costs of reproduction. Although I think that Bonnet et al. misconstrue the aims of some other studies, including one of my own, I found much of value in this chapter. One fascinating observation for me is that female Aspic Vipers (*Vipera aspis*), which Bonnet et al. study, have extremely high costs of reproduction, especially manifested in postpartum mortality, which makes these animals effectively semelparous (see also Luiselli and Zuffi's chapter in the Ecology section). This contrasts markedly with the rattlesnakes discussed elsewhere that experience long lives and multiple opportunities for reproduction (see chapters by Greene et al., Beaupre, Martin). Why are the costs so different in these two groups of vipers? Even more important, why is there no discussion of this among authors?

The selection of chapters mentioned above is biased to some extent by my own interests, but there are far too many chapters for me to discuss them all individually in any case. I will not even attempt to list them all. However, topics covered, in addition to those I already have noted, include: phylogenetic correlates of food habits (Martins et al.), caudal luring (Reiserer), patterns of rattle loss (Rowe et al.), the fossil record of vipers (Szyndlar and Rage), translocation of "problem" rattlesnakes (Nowak et al.; Sealy), and what I can only describe as adaptive constipation (Lillywhite et al.).

Despite numerous strengths, *Biology of the Vipers* also has significant weaknesses. The more trivial of these are technical details that suggest inattentive proofreading and editing. After awhile, I gave up trying to keep track of the numerous typographical and grammatical errors, but examples are not difficult to find (e.g. "Craycraft" instead of "Cracraft" on p. 40; "climactic" instead of "climatic," p. 287; "determinate" instead of "determinant," p. 567). The book generally is well presented and has a nice appearance, but there are signs of running ink in Fig. 4 of Reiserer's chapter. These points, however, are minor; my somewhat muted enthusiasm for this book is based on more substantive criticisms.

First, I think that the editors should have been much more ruthless in limiting the length of some of the longer chapters, including their own. Second, the detail in a couple of chapters verges on presentation of raw data. Readers cannot be expected to assimilate that which has not been properly digested (and this book is a big meal to begin with). In some cases, the data simply are too thin for meaningful inferences to be drawn, a situation that will not be helped by further analysis (or catalysis), only by further fieldwork or experimentation. Thus, one real problem with this volume is that some of the work presented is incomplete and prematurely published. Schuett et al. even acknowledge this in a curious paragraph concluding the introduction to their chapter. Admittedly, it can be difficult to recognize the logical stopping point for a study, and all studies are snapshots of ongoing work, but in the end, something is either publishable or it is not. *Biology of the Vipers* would have benefited from application of some of the same standards used in most journals. It also would have benefited from closer integration among chapters. The result would have been a leaner, tighter, and better book.

All this makes me ask: What motivates an author to publish a chapter in a book rather than a paper in a journal? After all, the latter is usually seen as more valuable from the point-of-view of earning grant funds, etc. I suspect that the answer lies, at least partly, in the opportunity to review a body of work (e.g., Hayes et al.) or to expand on a topic in a detailed way that might not be possible in the confines of a journal article (e.g., Greene et al.). Also, book chapters, especially those based on conference proceedings like this one, offer an opportunity to publish "works in progress," which may or may not see the light of day later in more fully developed form in a journal. These are worthwhile aims and, done well, this kind of diversity is more than welcome. However, it also is a bit risky.

Would *Biology of the Vipers* have been a better book had it not been based on proceedings of a conference? Not necessarily—but I think conference proceedings work better when the resulting volume is more selective and focused on specific, well-integrated topics. I, and others who study snakes, will find this book valuable and no doubt use it frequently in both research and teaching. Others will consult it now and then to find a snake example of this or that. However, with no clear conceptual focus, it likely will not attract a broader audience. *Biology of the Vipers* is a good book with some very bright spots indeed, but it is not as good a book as it could have been.

Vipers are in! This is demonstrated by a wealth of recently published studies (e.g., Thorpe et al. 1997; Joger 1999; Schuett et al. 2002). This was not always the case, however, as the genesis of this book demonstrates. David Mallow, a keeper of several viper species and an amateur herpetologist, started this project ten years ago because he could not find any specific books about his passion. He was quickly joined in this task by his friend David Ludwig. The initial phase was an extensive literature search that soon produced a massive listing of references. The authors then tackled the formidable task of collecting these documents, driving around the country, spending nights in motels and days in universities or museums, photocopying hundreds of papers. Finally, these articles were read and summarized (D. Mallow, pers. comm.). The manuscript was almost ready for publication when the editor strongly advised the authors to bring Nilson (Head of the Vertebrate Department, Göteborg Natural History Museum) into the project: "We used your [Golay et al.] 1993 collaborative book on endoglyphs as the foundation for our [taxonomic] system. However, as we were finishing the book it was brought to our attention by our editors that the taxonomy we were using was evoking a great deal of criticism especially with [respect to] the European vipers" (D. Mallow, in litt.).

True Vipers is divided into 14 taxonomic chapters preceded by a table of contents, a preface, authors' acknowledgments, and an introduction, and followed by the bibliography and a glossary. Within the taxonomic accounts species are ordered alphabetically within genera (or subgenera), and genera are likewise alphabetical within subfamilies. Oddly, however, non-nominate subgenera do not appear to follow any particular pattern.

The Preface clearly states the objective of the work, which is to "furnish the reader with a summary of taxonomy, general biology, and toxinology for vipers." The Introduction defines the scope of the study, which is limited to the "true vipers," which, among the Viperidae, are distinguished from the Crotalinae by the lack of thermo-receptive pit between the nostril and eye. Thus, this book is devoted to the subfamilies Azemiopinae, Causinae, and Viperinae. Parts of this introduction are real masterpieces, especially the sections treating the venom delivery system, toxinology, venom effects, and the treatment of snakebites. The authors do their very best to explain complex phenomena in a simple and didactic way; Sherman Minton would have been proud of his protégés. In this section, we also see the first signs of the most striking aspect of this publication, its lack of cohesion. This singularity, found all through the work, is evident in the disparity between the taxonomic and natural history/toxinology parts of the introduction (1.5 vs 9.5 pp.); despite his undeniable experience, Nilson did not have enough time (six months – G. Nilson, pers. comm.) to bring his contribution to the level of thoroughness of his coauthors.

The format of the taxonomic accounts was mostly inspired by Carl Ernst's (1992) *Venomous Reptiles of North America* (D. Mallow, pers. comm.), but because of the great disparity of information available, the authors were unable to strictly follow this model. This fact is clearly illustrated by the variable size of entries (from the thickest account, for *Bitis gabonica* – 14 pp., to the thinnest one, for *B. worthingtoni* – 1.5 pp.). The accounts are divided into sections: Recognition (Head, Body, Size, Pattern), Taxonomy and Distribution, Habitat, Food and Feeding, Behavior, Reproduction and Development, Bite and Venom (Epidemiology, Yield, Toxicity, Content, Symptoms and Physiological Effects, Hematological Activity, Case Histories, Treatment and Mortality) and Remarks (i.e., breeding, conservation, enemies, longevity, mimicry). Smaller accounts often lack the Remarks section and in many cases no information is provided under one or more of the other headings.

The bulk of the book is divided into 14 chapters. The content of six of them, Azemiopinae (genus *Azemiops* – 1 species), Causinae (genus *Causus* – 6 spp.), *Cerastes* (3 spp.), *Eristicophis* (1 sp.), *Montatheris* (1 sp.), and *Proatheris* (1 sp.) is non-controversial and raises no particular problems. The same cannot be said of the remaining taxonomic sections.

Chapter 3 Viperinae (genus *Adenorhinos* – 1 sp.) exhibits an especially disconcerting feature of this volume – the inconsistency of criteria used for the recognition of taxa. Not surprisingly, Nilson's decisions are mostly based on biochemical investigations performed by Ulrich Joger and his team. Although the authors "understand that full taxonomic agreement is not likely for some time to come," some taxonomic units seem to reflect an underlying "splitter's" point of view, whereas others follow a "lumping" approach. The most significant systematic changes espoused are derived from a single paper by Lenk et al. (2001). However, the way Nilson analyzes the results obtained is puzzling. Concerning *Adenorhinos*, the "splitting" policy was used, despite the fact that Lenk et al. demonstrated that *A. barbouri* and *Atheris ceratophora* are sister taxa.

Chapter 4 (genus *Atheris* – 12 species) reveals a problem in accounting: according to the table of contents, the genus *Atheris* contains 11 species; however, we later learn that "the genus *Atheris* currently includes 12 species" (p. 39) (the recently described *Atheris hirsuta* being mentioned only in the Taxonomy and Distribution section of the generic account).

Chapter 5 (genus *Bitis* – subgenera *Bitis* [1 sp.], *Calechidna* [11 spp.], *Macrocerastes* [3 spp.], and *Keniabitis* [1 sp.]) presents another inconsistency: "the two subspecies *Bitis g. gabonica* and *B. g. rhinoceros* are separated on species level by Lenk et al. 2001"

(p. 60) and "Currently two subspecies are recognized: *B. g. gabonica* … and *B. g. rhinocerus* (sic)" (p. 102); the "lumping" policy being here followed.

A significant taxonomic change is proposed in Chapter 7 (genus *Daboia* – 2 spp.) with the inclusion of *D.* (*Vipera*) *palaestinae* based on the findings of Lenk et al. However, the results of Lenk et al. are not taken to their logical conclusion, as following this would imply that *Macrovipera deserti* and *M. mauritanica* should also be included in the genus *Daboia.* Thus, Nilson here adopts a "splitting" policy.

Chapter 8 (*Echis* – 10 spp.) confirms the elevation of *Echis khosatzkii* (formerly included in the synonymy of *E. p. pyramidum*) to species level, as well as the questionable validity of the species *E. multisquamatus*, a probable subspecies of *E. carinatus*. The presence of *E. leucogaster* in Morocco is overlooked.

Chapter 10 deals with *Macrovipera* (4 spp.). As already mentioned, *Macrovipera deserti* and *M. mauritanica* should be included in the genus *Daboia* according to the results of Lenk et al. In this chapter Nilson resurrects *Macrovipera schweizeri siphnensis*, a form originally described by Wettstein (1952) on the basis that "the form from Siphnos is larger and has a different color pattern than the nominate subspecies" (Cattaneo 1989). The taxonomic conclusions expressed here are a good illustration of mixed "lumping" and "splitting" policies.

Chapter 13, *Pseudocerastes* (1 sp.), is another example of the "lumping" policy, Lenk et al. having clearly demonstrated that *Pseudocerastes fieldi* and *P. persicus*, here regarded as subspecies, should be treated as separate species.

As expected, Chapter 14, which considers *Vipera* with its subgenera *Pelias* (8 spp.), *Acridophaga* (6 spp.), *Montivipera* (8 spp.), and *Vipera* (5 spp.), is the most controversial part of the book. Concerning the subgenus *Pelias*, there is once again a mismatch between the table of contents and the systematic accounts, *Vipera magnifica* and *V. orlovi* being mentioned only in the *V. kaznakovi* account. To be fair, however, Nilson mentions that "additional research will demonstrate whether these taxa are full species or incipient species." The *V. darevskii* and *V. dinnicki* accounts clearly exemplify the danger of the "cut and paste" technique; the two accounts feature identical paragraphs concerning the mean length and weight of newborns. In this section, the "splitting" policy is invariably followed: "*Vipera nikolskii* could either be looked upon as a subspecies of *V. berus*, or as a full species;" moreover, *Vipera pontica* retains its species status, whereas according to Baran et al. (2001), it should be placed in the synonymy of *V. barani*.

In the subgenus *Vipera*, *V. transcaucasiana* is treated as a full species (see Herrmann et al. 1987); however, the possibility of the convergent evolution of *V. latastei* and *V. ammodytes transcaucasiana* albumins cannot be definitively ruled out. The *Vipera aspis* and *berus* accounts illustrate some irritating features: (1) In the Distribution section, the authors repeatedly cite general references (e.g., Street 1979; Mehrtens 1987, etc.), whereas David and Ineich (1999) and various European herpetological atlases are entirely ignored. (2) Statements are sometimes quite loosely interpreted. For example, in the Food and Feeding section, the authors write that "neonates eat insects and worms" whereas the original sentence is "the very young are said to eat insects and worms" (Street 1979, without substantiation). Further, their assertion that amphibian prey are not taken is incorrect (see Monney 1993 for evidence of frogs as prey of this species); (3) Blinded by their quest to be exhaustive, the authors were not critical enough to properly evaluate the reliability and currency of different sources of information, such as peer-reviewed articles, compilations, and "gray" literature; a good illustration of this failure is the sempiternal citation of U.S. Navy (1991) (which should be correctly cited as Moore 1991), an unaltered reprint of a 1966 book that is significantly out of date in many respects; (4) truisms, such as "most bites occur from March through October," are found even in Nilson's "secret garden" (the *V. berus* account).

In such a thorough review of the world literature, a bibliography plays an essential role; one must be able to easily retrieve cited works. Alas, in the preface alone, two out of four citations contain errors (Golay et al. 1993 and Herprint International [i.e., Ulber] 1994) and a third one (David and Ineich 1999) is not to be found in the bibliography. These unexpected errors drove me to test this section for its completeness. I verified that the citations mentioned in every 10th page (i.e., pp. xi, 7, 17, 27 … 297) were present among the bibliographic entries. One citation was lacking (Cherlin 1990) and I spotted two misprints (Laurent instead of Laurenti 1768 and Schnurrenburger instead of Schnurrenberger 1959). I accidentally found other missing entries (Darevsky 1956, Herrmann et al. 1987, Nilson et al. 1994) and misprints (Stucki-Stern instead of Stucki-Stirn 1979, Mierte instead of Meirte 1992).

Checking the accuracy of the bibliography, I was stunned! I found countless errors concerning dates of publication (e.g., Laurenti 1798 instead of 1768), editors (e.g., Calmette A. 1907 *In* Bucherl W., editor. 1967), pagination (Pitman 1938, 27 pp. instead of 362 pp.), patronyms (e.g., Boonpucknoaviq instead of Boonpucknavig), publishers (e.g., Klemmer 1967a *In* Bucherl W. – Masson, Paris instead of Academic Press, New York), and titles (e.g., *Historic Amphiorum naturalia et litterariae* instead of *Historiae Amphibiorum naturalis et literariae* Schneider 1801). Moreover, out of 65 French references, 52 contain errors! Among these is a real howler: "Geoffroy E, Saint-Hilaire T. 1827 Description del reptiles quo se trouvent en Egypt. In: Audouin V [editor]. Description de l'Egypte, ou recueil observations et Del recherches quo Ott en Egypt pendant l'expedition de l'Armee Franchise. Hist. Nat 1(1) :121–160." However, accuracy is much better for Spanish and German, despite the failure to capitalize some words or use proper diacritical marks.

Unfortunately, the manuscript of this potential bestseller apparently received little, if any, copyediting and was not subject to rigorous peer review. It is obvious that my complaints are negligible relative to the formidable amount of work produced by the authors. Therefore, I have no hesitation in recommending this excellent summation of the natural history and toxinology of true vipers as a reference. However, the taxonomic part of this volume proves that Krieger has come closer to the goal of gaining maximum profit on minimal investment than it has to reaching "the frontier of knowledge of viper taxonomy" (quote from rear cover of *True Vipers*).

WILLIAM E. DUELLMAN
Natural History Museum and Biodiversity Research Center
The University of Kansas, Lawrence, Kansas 66045, USA
e-mail: duellman@ku.edu

Nearly half a century has passed since the calls of North American anurans recorded by the late Charles M. Bogert with archaic recording equipment were transcribed onto a vinyl record (Bogert, 1958). Since then the recording of animal sounds has become a routine effort for many field biologists. Many recordings have been edited, grouped, and transcribed onto compact discs, especially by the Cornell Laboratory of Ornithology, which currently offers dozens of CDs of bird songs and three of North American anurans.

In recent years, herpetologists have been blessed with CDs of calls of frogs from various parts of the world (e.g., West Africa by Grafe 2000 and Panama by Ibáñez et al. 1999, containing recordings of 24 and 52 species, respectively). The two sets of discs reviewed here are the results of ambitious projects that required untold effort. With few exceptions the recordings are of good quality, although in many, background noise, principally calls of other species, is distracting. Both CDs are accompanied by small booklets (12 x 12 cm) containing brief comments on, and small color

photographs of, each species. Throughout the following commentary, the two works are referred to as "Bolivia" and "Tambopata."

Tambopata contains recordings of 70 species—3 bufonids, 1 centrolenid, 5 dendrobatids, 36 hylids, 21 leptodactylids, and 4 microhylids. All are identified to species, except a *Dendrophryniscus*, a *Hyalinobatrachium*, a member of the *Eleutherodactylus lacrimosus* Group, and a member of the *Hyla parviceps* Group that likely is *Hyla bokermanni*. Two distinctly different calls referred to *Osteocephalus "leprieurii"* are given; likewise there are recordings of *Adenomera* Species 1 and Species 2, in addition to *Adenomera andreae* and *A. hylaedactyla*. The call of a *Phyllomedusa*, noted as a yet-to-be-described species, is that of *P. camba* (De la Riva 2000a). The nomenclature of *Scarthyla ostinodactyla* should read *Scarthyla goinorum* (De la Riva 2000b). All recordings are from the vicinity of the Explorer's Inn on the Río Tambopata, Departamento de Madre de Dios, Peru, except for two each from Cocha Cashu and Pakitza in the same department. The brief account of each species includes a statement on breeding and specifics about the recording, usually temperature and always tape number in the United States National Museum or the Macaulay Library of Natural Sounds. Most of the color photographs are of good quality and despite their small size (27 x 23 mm) are useful in identifying the frogs.

Bolivia contains 166 recordings; 151 of these are of 129 species—8 bufonids, 3 centrolenids, 8 dendrobatids, 53 hylids (including 2 pseudines), 53 leptodactylids, and 5 microhylids. All are identified to species, except one *Colostethus* and one *Adenomera*, neither of which is represented by a photograph in the booklet. There are two recordings of 12 species, three of two species, and four of another. Most of these are simply recordings from two or more localities, but there is a release call of *Atelopus tricolor*, an aggressive call of *Ceratophrys cranwelli*, and a distress call of *Pseudis paradoxa*. The brief account of each species (English and Spanish) includes statements on breeding and distribution, calls of other species in the background, locality and temperature at time of recording, and name of person responsible for the recording. There is no documentation regarding the disposition of the recordings, but they are deposited in the Fonoteca Zoologica Digital in the Museo Nacional de Historia Natural (I. De la Riva, pers. comm.). Most of the 15 recordings of choruses include calls of 2–10 species, but three are of large choruses of single species—*Leptodactylus fuscus*, *L. rhodonotus*, and *Pseudopaludicola mystacalis*. Most of the photographs are reasonably good, but their small size (18 mm square) limits their utility.

Together, these two sets of CDs contain recordings of 151 species of anurans; 48 of the species nominally are included in both sets. However, taxonomic issues plague both publications. For example, the systematics of the toads of the "*Bufo typhonius* complex" is unresolved; a member of this complex is referred to *Bufo* cf. *typhonius* in Tambopata and as *Bufo margaritifer* in Bolivia; their calls are different. The distinctiveness of calls among cryptic species of *Adenomera* probably will result in at least two new taxa being recognized in Bolivia and Peru (Angulo and Icochea 2003). Two "species" of *Osteocephalus leprieurii* are recognized in Tambopata and another as *Osteocephalus* sp. in Bolivia. Three different calls are involved; most likely none of these is *O. leprieurii* as defined by Jungfer and Hödl (2002). However, these CDs are incredibly valuable for anyone studying calls of South American anurans. Individual calls can be downloaded into sound analysis programs (e.g., Canary) that can measure call parameters and produce waveforms and spectrograms, thus allowing other recordings to be compared with those on the CDs.

Both booklets emphasize that the CDs will be helpful in identifying frogs in the field and in monitoring frog populations. Theoretically, if a biologist is in the rainforest in southern Peru or adjacent Bolivia, and if he/she has a portable CD player, he/she could identify frogs by comparing calls heard in the field with those on the CDs. This is easier said than done. Very few persons have the auditory abilities and memory to recognize scores or even hundreds of sounds, as did the late Theodore H. Parker III for bird songs. Nevertheless, as stated by Zimmerman (1994), CDs such as these can be useful learning tools for auditory monitoring of anuran populations in the regions covered.

PUBLICATIONS RECEIVED

Crocodiles: Inside Out, A Guide to the Crocodilians and their Functional Morphology, by K. C. Richardson, G. J. W. Webb, and S. C. Manolis. 2002. Surrey Beatty & Sons, Chipping Norton NSW, Australia (distributed in the US by Bibliomania! – www.herplit.com). viii + 172 pp. Hardcover. AU$ 99.00 (US$ 65.00). ISBN 0-949324-90-6.

This book is a detailed guide to the anatomy of crocodilians, aimed at a wide audience, including those working with crocodiles and alligators commercially, as well as veterinarians and zoologists. It opens with an introductory chapter on crocodilian taxonomy and diversity and another on topographic dissection. It then takes a classic systems approach to anatomy, with chapters on the integument, skeleton, musculature, cardiovascular system, respiratory system, digestive system, urogenital system, and nervous and special sensory systems. These contain boxed insets on a variety of peripheral, but related topics, such as indicators of age in crocodilians, growth, diving, and vocalization. A chapter on histology covers tissues from all organ systems. A series of appendices cover muscle topography, the vascular system, and neuroanatomy, providing details of terminology, function, and position in tabular form. The book concludes with a "Further Reading" section of more than 200 references and a list of relevant websites, a glossary of more than 250 terms, and a comprehensive index. The volume is illustrated throughout, chiefly in color. Although many of the illustrations and observations are based on the two Australian species of crocodiles, the work is aimed at a more global audience including all crocodilian biologists as well as reptile morphologists.

De Dos Mundos, Las Ranas, Sapos y Salamandras de la Peninsula de Yucatán, Mécico/ Of Two Worlds, The Frogs, Toads and Salamanders of the Yucatan Peninsula, Mexico, by Carlos Galindo-Leal. 2003. Pangaea, Saint Paul, Minnesota (info@pangeae.org). xvii + 133 pp. Softcover. US $19.95. ISBN 1-929165-52-8.

This small bilingual book, with Spanish and English text on facing pages, covers the two species of salamanders and 20 species of anurans occurring on the Yucatan Peninsula. It is illustrated throughout by Roberto Arreola Alemón. Although clearly aimed at a non-technical audience, the book provides a good deal of detailed information in accessible form. Among the topics covered are activity, reproduction, life history stages, vocalization, diet, and defense. These are grouped under whimsically entitled chapters such as "Multiple Personalities" and "Tenors, Baritones and Basses." What makes the book unique is the integration into the main text of quotes, poems, proverbs, and stories relating to amphibians. These derive from sources as diverse as Aesop and Jimmy Buffet songs and originate from countries from China to Germany to Argentina, and of course Mexico. Species accounts are just a few paragraphs in length and provide etymological information, basic identifying features, a summary of habitat and reproduction, and a statement of distribution. Each is accompanied by a color illustration. The book concludes with sections on human uses of amphibians, from Mayan rain invocation rituals to pregnancy tests, and a consideration of conservation, with details relating to vulnerable amphibians of the Yucatan and the success of the cane toad, *Bufo marinus*. Short lists of relevant literature and websites are also provided.

Reptiles and Amphibians of the Amazon: An Ecotourist's Guide, by R. D. Bartlett and Patricia Bartlett. 2003. University Press of Florida, Gainesville, Florida (www.upf.com). xviii + 310 pp. Softcover, US $29.95. ISBN 0-8130-2623-7.

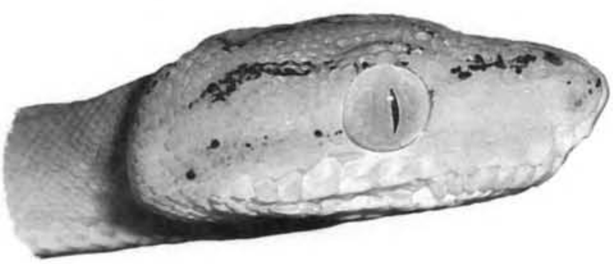
This latest offering from the prolific herpetological writing team of Bartlett and Bartlett provides travelers to Amazonian South America a convenient and colorful introduction to the region's impressive herpetofaunal diversity. Aside from the 310 pages of text, there are an additional 128 pages (unnumbered) containing 297 color photographs of herps, habitats, and predators. Photo quality is mostly good to excellent, with more than 250 taxa depicted. Although not exhaustive in its coverage, the authors have included those species most likely to be encountered by ecotourists, especially in Amazonian Peru. Brief written accounts for each of the included species offer information on size, identification, reproduction, similar species, habitat and range, and voice (for anurans). Tips for travel in the neotropics include things like clothing, medications, currency exchange, field gear, and items useful when trading with the locals.

Parental Behavior in Lepidosaurian and Testudinian Reptiles, A Literature Survey by Louis A. Somma. 2003. Krieger Publishing Company, Melbourne, Florida (www.krieger-publishing.com). x + 174 pp. Hardcover. US $33.50. ISBN 1-57524-201-X.

This book brings together the extensive literature on parental behavior (defined as "all behavioral contributions by the parent(s) to offspring survival *after* parturition"). After a brief overview of selected historical, legendary, and folkloric views of parental behavior in non-archosaurian reptiles, the author defines 19 categories of parental behavior (including several reflecting varying degrees of reliability). These are employed in a series of three tables (one each for turtles, snakes, and non-ophidian lepidosaurs) that list the type(s) of parental care and the reference(s) reporting for each of 336 species of lepidosaurs and 7 turtles. Two summary tables list the number of genera and species exhibiting parental behavior by family, and the prevalence of maternal, paternal, and biparental behavior across lepidosaurs. Additional tables more briefly overview parental behavior in other extant vertebrates and in extinct reptiles, experimentally-derived studies of parental behavior, and historical literature dealing with snakes swallowing their young. The bibliography of parental behavior is 100 pages long and includes citations from Gesner and Topsell to the 21st Century, derived from the literature of natural history, herpetoculture, and other sources. A combined subject and taxon index to the tables and introductory material completes this useful reference.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–2003, *et. seq*. Privately published by and available from the author (Ralph W. Axtell, 1033 Randle Street, Edwardsville, Illinois 62025, USA; e-mail: raxtell@siue.edu). Individual accounts available separately. Cost: US $0.15/page + postage and handling.

The most recent installments (numbers 27–28) in this series are *Scincella lateralis* (Little Brown Skink) and *Cnemidophorus exsanguis* (Chihuahuan Spotted Whiptail). These new accounts comprise 41 and 10 pages, respectively, in addition to a detailed range map. Axtell provides an in-depth discussion of distribution for each species in Texas, along with current taxonomy, geographic variation, conservation status, and suggestions for future work. He retains usage of *Cnemidophorus sensu lato*, treating *Aspidoscelis* as a subgenus (by extension, *Ameiva* and *Kentropyx* are also regarded as subgenera) pending further resolution of phylogenetic relationships among teiids.



Corallus hortulanus (Common Tree Boa). Guyana. Photolithograph by Will Brown.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.html>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information on inside front cover) or from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Peabody Museum of Natural History, Yale University, P.O. Box 208118, New Haven, Connecticut 06520-8118, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Donald Schmitt, SSAR Membership Office, P.O. Box 253, Marceline, Missouri 64658, USA. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 35, Number 1 (March 2004).

CAUDATA

CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS (Eastern Hellbender). **BREEDING SEASON**. The breeding season of eastern populations of *Cryptobranchus a. alleganiensis* has been fairly well documented in the literature. In general, the season lasts from mid-August through mid-September (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press. 587 pp.), although in Alabama it can continue into early October (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agri. Exp. Station. 347 pp.). Herein, we report what we believe to be the first documented records of gravidity and nesting from Georgia, perhaps the southeastern-most state within this salamander's range.

In an effort to collect skin mucous for bacterial analyses, we hand-captured *C. alleganiensis* at Cooper Creek, Union County, Georgia on 5 Sept 2002. Among the hellbenders captured were two gravid females, one of these discharged ca. five eggs when placed in a dilute solution of MS-222 to anesthetize the animal. Additionally, a nest guarded by an adult hellbender was discovered under a large flat rock. We immediately replaced the rock and did not collect either the eggs or the adult. We were not able to confirm the sex of this animal.

A previous collection trip to this same section of creek on 22 July 2002 yielded seven adult male and two adult female *C. alleganiensis*, none in reproductive condition.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@dnr.state.ga.us), **CARLOS D. CAMP, RICHARD M. AUSTIN, JR.,** and **R. ALEX PYRSON**, Department of Biology, Piedmont College, 165 Central Avenue, Demorest, Georgia 30535, USA, **LAINE GIOVANETTO, SEAN GRAHAM**, and **MELANIE MEADOWS**, Department of Biology, Georgia State University, P.O. Box 4010, Atlanta, Georgia 30302-4010, USA, and **DEAN DEMAREST**, United State Fish and Wildlife Service, 1875 Century Boulevard, Suite 240, Atlanta, Georgia 30345, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). **REPRODUCTION**. Detailed life histories are known for only a few populations of the *Plethodon glutinosus* complex and include several reports of egg clutches and very few reports of new hatchlings (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Smithsonian Instit. Press, Washington, D.C. 587 pp.).

On 24 Oct 2002, we discovered a female *P. glutinosus* (72 mm SVL) attending a newly laid clutch of eggs in Pettijohn Cave in Dickson Gulf on the eastern side of Pigeon Mountain, Walker County, Georgia, USA. The clutch was located in a horizontal crevice in the limestone rock of the cave wall ca. 1.3 m above the cave floor. It was suspended by a pedicel from the roof of the crevice and consisted of 17 eggs, each measuring 6.0–6.1 mm in diameter. The clutch was ca. 12 m from the cave opening. The outside air temperature was 16.5°C; the temperature inside the cave was 13.0°C. We monitored the clutch through the winter, revisiting it on 14 Dec 2002, 21 Jan, 9 Feb, and 1 March 2003. On 14 Dec 2002 the pedicel was broken, and the eggs lay in a heap on the floor of the crevice. The loss of suspension did not seem to interfere with development or the female's attendance. The significance of the 12-m distance from cave opening became apparent on cold days during the winter. The clutch was located at a depth closest to the opening where the thermal environment was relatively stable.

On 2 March 2003, one egg had hatched. The hatchling measured 16.4 mm SVL and 19.7 mm total length. Its belly was extended with yolk, it had distinct gills, and skin pigment was poorly developed. Because *Plethodon* hatchlings resorb their gills within a few days of hatching (Highton 1956. Copeia 1956:75–93) and because the other eggs seemed healthy and unhatched, we presumed that the hatchling was < 24 h old. Therefore, the gestation period was 128+ days.

This represents the latest seasonal dates of oviposition and hatching for the complex and >1 month later than those reported from caves in northern Alabama (Highton 1962. Copeia 1962:597–613). These were also the largest eggs and the longest gestation period reported for the *P. glutinosus* complex (Petranka 1998, *op. cit.*).

Submitted by **CARLOS D. CAMP**, Department of Biology, Piedmont College, P.O. Box 10, Demorest, Georgia 30535, USA (e-mail: ccamp@piedmont.edu), and **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@dnr.state.ga.us).

ANURA

BUFO PARIETALIS (Forest Toad). **PREDATION.** Although the toxic secretions of toads are repellent against many predators, there are numerous reports for predators of toads throughout the world (Haddad and Rogério 1997. Amphibia-Reptilia 18:295–298). The population ecology and the natural predators of amphibians in the forest ecosystems of India are poorly studied. *Bufo parietalis* is a rare and little-known toad, endemic to tropical rainforests of the Western Ghats (Molur and Sally 1998. Zoo's Print 13[12]:29). Since 1999, we have observed the natural history of *B. parietalis* as part of population studies. Herein, we report predation by an invertebrate (mosquito) and a vertebrate (bird) on males engaged in reproductive activity in Karnataka, South India.

On 22 Feb 2001, we observed large breeding populations of *Bufo parietalis* at two sites on the western slope of Western Ghats within the Bisale Reserve Forests (12°15'N; 75°37'E, 150 m elev.). At 1700 h we witnessed a large number of mosquitoes feeding on calling toads (59.8–73.5 mm SVL; N = 8). Mosquitoes were observed to suck blood mainly from the limbs rather than other body parts. The toads were disturbed by the bites and kicked the limbs sideways in an attempt to drive away the mosquitoes. As they kicked and rubbed the face they would stop calling. To get rid of the mosquitoes they also dove into the water and floated on the water with only the face above the surface. The toads surfaced when the mosquito flew from the body. The mosquitoes were identified as *Culex quinquefaciatus*. Although *Aedes aegypti* was found in the same habitat attacking humans, they were not found preying on the forest toads.

On 7 April 2000 at 0600 h, 360 m elevation, we observed a jungle crow (*Corvus macrorhynchos*), preying on an adult *Bufo parietalis* (69.8 mm SVL, 23.5 g) on a road that passes through the forest, thereby opening the canopy cover. The crow was observed to open the abdominal cavity and feed on the visceral contents. The skin and the limbs were not eaten. We also observed the crow prey on breeding adults by stepping on the hind limbs and pecking the eye and head from behind. During the late breeding season, adult male *B. parietalis* are found actively searching for the females. The risk of predation is increased as toads enter an open canopy area where they are more readily seen by crows.

Submitted by **SAVITHA KRISHNA** and **K. K. VIJAYALAXMI**, Department of Biosciences, University of Mysore P.G.C., Hemagangothri, Hassan, Karnataka 573220, India.

BUFO PELTOCEPHALUS (Cuban Toad). **DIURNAL RETREAT**. *Bufo peltocephalus* is a large Cuban toad that lives in most habitats in the central and eastern Cuban archipelago. Maximum female SVL is 163 mm (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, 720 pp.). This toad diurnally retreats underground, protected by rocks, stones, palm leaves or other vegetation. It may excavate its own tunnels, or use the burrows of Burrowing Owls (*Athene cunicularia*) (Valdés 1978. Misc. Zool. 7:4; Schwartz and Henderson 1991, *op. cit.*). During the first hours of the night it emerges from the retreat to feed and mate.

From 12 to 17 May 2003, we studied the herpetofauna of Península de Zapata (Zapata Swamp), Matanzas Province, Cuba. During the nights of 12–13 May we observed a group of toads in the yard at the Cuban Ministry of Science, Technology, and Environment, between Pálpite and Playa Larga (22°19'02"N, 81°11'23'W). The habitat is a grassy lawn on a "diente de perro" limestone soil. Between 2105–2120 h the toads were emerging from the holes of the "diente de perro." This habitat is an unusual retreat for *B. peltocephalus* that has never been reported.

Herein we report a novel diurnal retreat for a Cuban bufonid and clarify its distributional status at one locality of Zapata Swamp. We thank Julio Guillermo Calvear for help during fieldwork. Special thanks for the staff of the office of the Cuban Ministry of Science, Technology, and Environment for logistic and scientific help.

Submitted by **VILMA RIVALTA GONZÁLEZ, LOURDES RODRÍGUEZ SCHETTINO, ADELA TORRES BARBOZA,** and **MERCEDES MARTÍNEZ REYES,** Departamento de Vertebrados, Instituto de Ecología y Sistemática, C. de Varona km 3.5, Boyeros, CP 10800, AP 8029, La Habana, Cuba (e-mail: zoologia.ies@ama.cu), and **JULIO LARRAMENDI JOA**, Calle 3ª #806, Playa, La Habana, Cuba (e-mail: jlarramendi@hotmail.com).

BUFO RUFUS (Rusty Toad). **DIET.** *Bufo rufus* ranges from Brazil (Goiás State and Minas Gerais State) to northeastern Argentina (Misiones) (Frost 1985. Amphibian Species of the World. Allen Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. 732 pp.). Aspects of the trophic ecology of this species have been little investigated in natural populations from central Brazil. We analyzed the gastrointestinal contents of 12 specimens (males: 72.4 ± 8.92 mm SVL, N = 4; females: 89.62 ± 11.04 mm SVL, N = 8) collected during the Corumbá I Hydroelectric Power Plant reservoir formation (17°59'S, 48°31'W), Caldas Novas municipality, Goiás State, between Sept 1996 and April 1997. The diet of *B. rufus* was better represented numerically by Isoptera and volumetrically by Hymenoptera (Formicidae) (Table 1). The process of reservoir formation might have affected food resource availability and the local distribution of toads (Paiva 1999. Conservação da Fauna Brasileira. Ed. Interciência. Rio de Janeiro. 260 pp.).

TABLE 1. Prey consumed by *Bufo rufus* (N = 12) from Corumbá I Hydroelectric Power Plant reservoir, Brazil.

SILVA and NELSON JORGE DA SILVA JUNIOR, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Ave. Universitária 1440, Setor Universitário, 74.210-010, Goiânia, Goiás, Brazil.

HYLA ALBOPUNCTATA (Spotted Treefrog). **DIET.** *Hyla albopunctata* is distributed in central and southeastern Brazil, northeastern Argentina (Provincia Corrientes), and eastern Paraguay (Frost 1985. Amphibian Species of the World. Allen Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. 732 pp.). Aspects of the trophic ecology of this species have been little investigated in natural populations from central Brazil. We analyzed the stomach contents of 21 specimens (males: 54.41 ± 2.16 mm SVL, N = 6; females: 61.63 ± 4.04 mm SVL, N = 15) collected during the Corumbá I Hydroelectric Power Plant reservoir formation (17°59'S, 48°31'W), Caldas Novas municipality, Goiás State, between September 1996 and April 1997. The analysis indicated that the most frequently taken prey items were Araneae (N = 5; 35.71%), Blattaria (N = 1; 7.14%), Chilopoda (N = 1; 7.14%), Orthoptera (N = 4; 28.57%), and unidentified material (N = 3; 21.42%).

The volume (in mm^3) of the items were Araneae (spiders) 982.13 (21.86%), Blattaria 469.57 (10.45%), Chilopoda 638.69 (14.22%), Orthoptera 2321.11 (51.67%), and unidentified material 79.92 (1.77%). Araneae, Blattaria, and Chilopoda were present in only one stomach, Orthoptera in three, and unidentified material in two. Sixteen stomachs were empty. The diet of the 21 *H. albopunctata* studied was dominated numerically by Araneae and volumetrically by Orthoptera.

Ipiranga, 6681, CEP 90619-900, Porto Alegre, Rio Grande do Sul, Brazil (e-mail: wilianvaz@uol.com.br); **HELDER LÚCIO RODRIGUES SILVA** and **NELSON JORGE DA SILVA JUNIOR**, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Ave. Universitária 1440, Setor Universitário, 74.210-010, Goiânia, Goiás, Brazil.

HYLA CINEREA (Green Treefrog). **PREDATION.** McCormick and Polis (1982. Biol. Rev. 57:29–58) reported that the Okefenokee Fishing Spider, *Dolomedes okefinokensis* (Araneae, Pisauridae) preys upon treefrogs, but no particular species of treefrog was listed in their review. During an inventory of amphibians and reptiles in Big Cypress National Preserve, Collier County, Florida, USA, we observed *D. okefinokensis* preying on *Hyla cinerea* on two occasions.

On 15 March 2002 at 2330 h, a 40 mm (body length) *D. okefinokensis* was discovered with a 35 mm SVL *H. cinerea* in its chelicerae 50 cm above the 70 cm deep water on the stem of a bald cypress (*Taxodium distichum*). The skin of the treefrog had become transparent and the muscle was visible. On 4 Dec 2002 at 1950 h, a second *D. okefinokensis* was observed preying upon *H. cinerea*. This pair was found on a bald cypress buttress 35 cm above the water, and both the *H. cinerea* (SVL) and the *D. okefinokensis* (body length) were estimated to be 40 mm (Fig. 1).

Fig. 1. Photograph of *Hyla cinerea* held by the chelicerae of *Dolomedes okefinokensis*.

The pair was observed intermittently for 1.5 h, during which the *H. cinerea* lost some green pigmentation and started to become transparent. The *H. cinerea* continued to struggle for the entire 1.5 h. Both of these predation events were observed in flooded cypress domes (Myers and Ewel 1990. Ecosystems of Florida. Univ. Central Florida Press, Orlando, 765 pp.) with a long hydroperiod (ca. 9 months).

Submitted by **BRIAN M. JEFFERY**, **J. HARDIN WADDLE**, and **ANDREW J. MASKELL**, University of Florida, Big Cypress National Preserve, 33100 Tamiami Trail, Ochopee, Florida 34141, USA (e-mail [JHW]: hardin_waddle@usgs.gov).

HYLA CREPITANS (Emerald-eyed Treefrog). **DIET.** *Hyla crepitans* is distributed in central and northeastern Brazil, Guianas, northern Colombia and Venezuela, eastern Panama, and northern Honduras (Frost 1985. Amphibian Species of the World. Allen

Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. 732 pp.). Aspects of the trophic ecology of this species have been little investigated in natural populations from central Brazil. Herein we report the gastrointestinal contents of 20 specimens (males: 58.86 ± 1.75 mm SVL, N = 8; females: 58.8 ± 2.58 mm SVL, N = 12) collected during the Corumbá I Hydroelectric Power Plant reservoir formation (17°59'S, 48°31'W), Caldas Novas municipality, Goiás State, from September 1996 to April 1997. We were unable to determine % volume in some prey items. The diet of the 20 *H. crepitans* studied was better represented numerically and volumetrically by Coleoptera (Table 1).

Submitted by **WILIAN VAZ-SILVA**, Laboratório de Herpetologia, Faculdade de Biociências da PUCRS – Pontifícia Universidade Católica do Rio Grande do Sul. Av. Ipiranga, 6681, CEP 90619-900, Porto Alegre, Rio Grande do Sul, Brazil (e-mail: wilianvaz@uol.com.br); **HELDER LÚCIO RODRIGUES SILVA** and **NELSON JORGE DA SILVA JUNIOR**, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Ave. Universitária 1440, Setor Universitário, 74.210-010, Goiânia, Goiás, Brazil.

HYLA FABER (Smith Frog). **DIET.** During fieldwork on the *Araucaria* Plateau of Rio Grande do Sul, southern Brazil, various leptodactylid species were collected and stomach-flushed using the methodology described by Patto (1998. Herpetol. Rev. 29:156–157). On 27 Dec 2001 a male *Hyla faber* (95.3 mm SVL, 54.33 g), was observed within a pond near the Pró-Mata research station (29°30'S, 50°10'W) by M. Wittmann. As this specimen seemed to be unusually fat for a calling hylid male it was collected and stomach-flushed. A single adult male *Scinax granulatus* (36.2 mm SVL), one of the most common frogs of that region, was found in the stomach. The flushing of another male *H. faber* (87 mm SVL, 55.46 g), captured on 16 Nov 02 at 2300 h by BP near the Pró-Mata reserve, yielded insects and the fragments of an anuran leg (tibia and femur). On 5 Dec 2002 at 2200 h, a male *H. faber* (95.9 mm SVL, 66.36 g) caught on the border of an *Araucaria* forest near a small pool within the Pró-Mata reserve by MS contained an adult partly digested *Aplastodiscus perviridis*. Most hylids do not feed during the time they spend at the reproduction sites, but little is known about the diet of *H. faber*. To our knowledge this is the first report of anurophagy for this species.

We thank Marcos Di-Bernardo, Wolf Engels, and Wolfgang Maier for their cooperation.

HYLA RANICEPS (Chaco Treefrog). **DIET.** *Hyla raniceps* has a distribution in French Guiana, Brazil, Paraguay, northern Argentina and eastern Bolivia (Frost 1985. Amphibian Species of the World. Allen Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. 732 pp.). Ecological data for this species are scarce (Lutz 1973. Brazilian Species of *Hyla*. Univ. Texas Press, Austin and London, 260 pp.; Guimarães et al. 2001. Herpetol. Rev. 32:102; Peltzer and Lajmanovich 2001. Herpetol. Rev. 32:247–248) and the diet has been little investigated in populations from central Brazil. Twenty-five specimens (males: 67.01 ± 5.43 mm SVL, N = 17; females: 69.15 ± 7.37 mm SVL, N = 8) collected during the Corumbá I Hydroelectric Power Plant reservoir formation (17°59'S, 48°31'W), Caldas Novas municipality, Goiás State, between Sept 1996 and April 1997, had their gastrointestinal contents analyzed. Volume was not determined for prey classified as unidentified material. The diet of the 25 *H. raniceps* studied was better represented numerically and volumetrically by Orthoptera (Table 1).

TABLE 1. Prey consumed by *Hyla raniceps* (N = 25) from Corumbá I Hydroelectric Power Plant reservoir, Brazil.

LEPTODACTYLUS OCELLATUS (Rã-Manteiga). **DIET.** *Leptodactylus ocellatus* is found in many parts of Brazil. Its diet includes arthropods (Vaz-Ferreira and Gehrau 1975. Physis 34:1–14; Strussman et al. 1984. J. Herpetol. 18:138–146) and vertebrates (Haddad and Sazima 1991. Anfíbios Anuros da Serra do Japi, pp. 188–211). During the night of 11 Dec 2002, we collected an adult male *L. ocellatus* (105.9 mm SVL; Museu de Biodiversidade do Cerrado, UFU 2415) near a lake in Uberlândia municipality. Examination of the stomach contents revealed the skink *Mabuya*

dorsivittata (61.5 mm SVL; UFU 1204). The consumption of a heliothermal terrestrial lizard indicates that *L. ocellatus* forages during the day.

We thank Ariovaldo A. Giaretta for critically reading the manuscript.

PHYLLOMEDUSA HYPOCONDRIALIS (Orange-legged Monkey Frog). **DIET.** *Phyllomedusa hypocondrialis* has a distribution in South America east of the Andes from Bolívia, Colombia, and the Guianas southward to Argentina, Paraguay, and southeastern Brazil (Frost 1985. Amphibian Species of the World. Allen Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. 732 pp.). Some aspects of ecology of this species were discussed by Cei (1980. Amphibians of Argentina. Monitore Zoologico Italiano [NS]. Monogr. 2, 609 pp.) and Dure (1999. Herpetol. Rev. 30:92), but the diet has been little investigated in populations from Central Brazil. Twenty-five specimens (males: 32.16 ± 4.09 mm SVL, N = 10; females: 38.24 ± 3.14 mm SVL, N = 15) collected during the Corumbá I Hydroelectric Power Plant reservoir formation (17°59'S, 48°31'W), Caldas Novas municipality, Goiás State, between September 1996 and April 1997, had their gastrointestinal contents analyzed. Volume was not determined for prey classified as miscellaneous or unidentified material. The diet of the 25 *P. hypocondrialis* studied was better represented numerically by Hemiptera and volumetrically by Blattaria (Table 1).

PHYSALAEMUS NATTERERI (NCN). **ATTEMPTED PREDATION.** Many species of frogs have skin toxins that have an antipredatory function. *Physalaemus* species are known to have physalaemins in the skin, which act as a hypotensive and stimulate smooth muscles in vertebrates (Erspamer et al. 1964. Experimentia XX/9:489–490). *Physalaemus nattereri* experimen-

tally offered to *Nasua nasua* (Mammalia: Carnivora) produced poisoning and inhibited predation (Sazima and Caramaschi 1986. Rev. Biol. 13:91–101). Here we report field observations of two unsuccessful attempts at predation on *P. nattereri* by *Leptodactylus ocellatus*. Observations were made during the night at a pond where both frogs reproduce, in the municipality of Uberlândia (Minas Gerais, Brazil), between November and December 2002. On the first occasion, we saw an adult male *L. ocellatus* (80 mm SVL) swim toward a calling male *P. nattereri* (41 mm SVL) and capture him by the head. The predator swam back to the pond margin and tried to swallow the prey. While swallowing, the predator pushed at the prey with its hands. While being swallowed the prey remained motionless. The predator took 70 minutes to complete swallowing. After swallowing was completed, the predator was collected and placed in a plastic bag. After one minute in the bag the predator started to regurgitate the prey. When about half of its body was out of the predator's mouth, the prey started to struggle energetically until it became free. After the prey was released the predator started to repeatedly open and close its mouth and wipe it with its hands.

On a second occasion, we found an adult *L. ocellatus* with an adult *P. nattereri* already in its mouth, the prey being swallowed headfirst. Again the prey was motionless while being ingested. This time the predation attempt was aborted when the first half of the body of the prey was in the mouth of the predator. Remaining still while being swallowed may be an important strategy of *P. nattereri* to avoid injuries while in the predator's mouth. We believe that in both cases the abortion of the predation attempt was because of the action of skin toxins of *P. nattereri*.

We thank A. S. Rand, A. A. Giaretta, and M. N. C. Kokubum for critically reading the manuscript. FAPEMIG provided a fellowship to APR.

***PLEURODEMA BUFONINUM* (NCN) and *BUFO SPINULOSUS PAPILLOSUS* (NCN). PREDATION.** Spider predation of anurans has been frequently documented (Formanowicz 1984. Anim. Behav. 32:774–781; Mitchell 1990. Herpetol. Rev. 21:89–90; McLister and Lamond 1991. Can. Field-Nat. 105:574–575; Johnson 1996. Herpetol. Rev. 27:140; Rogers 1996. Herpetol. Rev. 27:75; Blackburn et al. 2002. Herpetol. Rev. 33:299; Griffin and Case 2002. Herpetol. Rev. 33:301). Herein we report the first account on predation of the wolf spider, *Trochosa albopunctata* (Lycosidae) on *Pleurodema bufoninum* (Leptodactylidae) and *Bufo spinulosus papillosus* (Bufonidae) tadpoles. During stream and ponds surveys on 29 Nov 2002, we searched for potential predators of *Pleurodema bufoninum* and *Bufo spinulosus papillosus* tadpoles. Four specimens of the wolf spider *Trochosa albopunctata* were captured along the edge of the Ñireco River (41°10' 52.3"S, 71°19'13.6"W), 906 m elev., 3 km NW San Carlos de Bariloche City, Río Negro Province, Argentina, and 3 km SW National Route 258. To determine if wolf spiders are potential predators of *Pleurodema* and *Bufo* tadpoles we established four adult spiders (mean = 10.6 mm body length; SE = 0.44) in the laboratory in four separate aquariums. The specimens were acclimated during 24 h and after this period, 3 tadpoles of each one of the anurans were offered to the spiders. A total of 48 tadpoles were offered to the spiders (*Bufo* N = 24, mean = 18.1 mm total length, SE = 0.59; *Pleurodema*, N = 24, mean = 21.6 mm total length, SE = 1.7). Tadpoles were replaced each time they were eaten by the spiders.

In the first 24 h each spider built a web and did not feed. After 48 h all spiders preyed upon *Pleurodema* and *Bufo* tadpoles. The spiders ate only one tadpole each day except one spider ate 3 tadpoles during a single day. Detailed observations of feeding were recorded in only one spider. We observed that the tadpole was anaesthetized by the spider, wrapped in the web, and later fed upon. After finishing feeding, skin remains of the tadpole were present in the spider web. To corroborate this observation, we conducted a field survey for spider webs containing tadpole rests. On 25 Jan 2003 on the Ñireco River foodplain eight spider webs were observed and three of them contained tadpole skin remains, presumably belonging to *P. bufoninum*.

Bufo spinulosus papillosus and *Pleurodema bufoninum* breed in a wide range of freshwater habitats across northern to southwestern Patagonia (Cei 1980. Monit. Zool. Ital. [NS] Monogr. 2: XII. 609 pp.). Tadpoles of these species are preyed upon by several groups of aquatic insects (dragonflies, damselflies, dytiscid larvae, hemipterans), and fish. However, the relative importance of wolf spiders as predators of *B. spinulosus papillosus* and *P. bufoninum* tadpoles remains unclear. We thank P. Goloboff for identifying the spiders.

***RANA AURORA AURORA* (Northern Red-legged Frog). ENDOPARASITES.** *Rana aurora* occurs from southwest British Columbia to northwest Baja California (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians. 3rd Ed., Houghton Mifflin Co., Boston, Massachusetts. 533 pp). The helminths of *R. aurora* from California are listed in Goldberg and Bursey (2002. Bull. So. Calif. Sci. 101:118–130). The purpose of this note is to report the presence of three helminth species in tadpoles of *R. a. aurora* from northern California. Fifteen *R. a. aurora* tadpoles were examined: one from Del Norte County (collected June 2002) and fourteen from Humboldt County (two collected June 2001 and twelve collected June 2002). The tadpoles were fixed in 10% formalin then preserved in 70% ethanol. The abdominal cavity was opened, the gastrointestinal tract removed, slit longitudinally and examined under a dissecting microscope. Helminths were removed to a drop of undiluted glycerol for identification. Digeneans were regressively stained in Mayer's hematoxylin and studied as wholemounts.

Found in the intestines were one species each of Digenea, *Megalodiscus microphagus*, Nematoda, *Gyrinicola batrachiensis*, and Acanthocephala, *Neoechinorhynchus rutili*. Helminths were

placed in vials of 70% ethanol and deposited in the United States National Parasite Museum (USNPC), Beltsville, Maryland as *Megalodiscus microphagus* (93429–30), *Gyrinicola batrachiensis* (93431), *Neoechinorhynchus rutili* (93432); tadpoles were deposited in the herpetology collection of the Natural History Museum of Los Angeles County as LACM 155028–35. Prevalence of infection (number infected tadpoles/number tadpoles examined) x 100 and mean intensity of infection (mean number of infected individuals) ± 1 SD and range were: *M. microphagus* (33%, 17.6 ± 27.3 SD, 1–65); *G. batrachiensis* (53%, 9.3 ± 7.1 SD, 2–22); *N. rutili* (7%, 2).

Megalodiscus microphagus was described originally from *Bufo boreas* from northern California by Ingles (1936. Trans. Amer. Microsc. Soc. 55:73–92) and has been reported in *R. aurora* from Oregon (Macy 1960. J. Parasitol. 48:662) and British Columbia, Canada (Efford and Tsumura 1969. Amer. Midl. Nat. 82:197–203). Our record is the first report of *M. microphagus* in *R. aurora* from California.

Gyrinicola batrachiensis is known from a variety of anurans (bufonids, hylids, ranids) from eastern North America (Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1–325). It apparently only occurs in tadpoles (Adamson 1981. Can. J. Zool. 59:1368–1376). *Rana aurora* represents a new host record for *G. batrachiensis*. California is a new locality record.

Neoechinorhynchus rutili has been reported from numerous fish species of the northern hemisphere (Van Cleave and Lynch 1950. Trans. Am. Microsc. Soc. 69:156–171). It is also known from *Rana esculenta* in Europe (Walton 1942. Contrib. Biol. Lab. Knox College 79:1–16) and *R. catesbeiana* from Canada (McAlpine and Burt 1998. Can. Field-Nat. 112:50–68). *Rana aurora* represents a new host record for *N. rutili*. California is a new locality record.

Tadpoles were collected under scientific collecting permit 803031-05 issued by the California Department of Fish and Game.

RANA AURORA DRAYTONII (California Red-legged Frog). **MICROHABITAT**. Little has been reported on microhabitat use by California red-legged frogs (*Rana aurora draytonii*). Cook (1997. MS Thesis, Sonoma State Univ., 23 pp.) investigated the utilization of microhabitats within marshes. Use of upland and other non-aquatic habitats have been reported by others (USFWS 2003. Recovery Plan for the California Red-legged Frog; Rathbun et al. 1997. Herpetol. Rev. 38:85–86). Here I report the use of an atypical, non-aquatic microhabitat by *R. a. draytonii*.

Five annual surveys were conducted between 1998 and 2002 on 90 managed ponds in the upper Kellogg Creek Watershed, Contra Costa County, California. Ponds were surveyed throughout the year or until they dried during the summer months. During surveys conducted from 1998 to 2002, *R. a. draytonii* were observed utilizing all 90 ponds.

In September 2000, I walked across the bottom of a dry pond. The pond had been dry (no surface water) since the previous survey 4 weeks earlier. Pond bottom substrate consisted of a silt/clay mix that was completely dry, leaving deep (>50 cm) desiccation cracks. While walking across this pond bottom, a single adult *R. a. draytonii* was observed within a deep crack in the dry pond (Fig. 1). The frog was resting at the bottom of the crack facing skyward. Closer investigation revealed apparent soil moisture in the deepest reaches of the cracks. In October 2000, 7 adult and 22 subadult *R. a. draytonii* were observed using similar cracks in two other ponds. There was no apparent standing water, and the ponds were otherwise considered dry. During pond surveys throughout 2001 and 2002, five additional dry ponds were found in which frogs were utilizing cracks several weeks after all surface water was gone. Frogs were found deep (>30 cm) within desiccation cracks where soil moisture was still apparent.

Many authors have reported the ability of amphibians to obtain moisture from damp soil (e.g., Stebbins 1945. Copeia 1945:25–28). These *R. a. draytonii* might also be avoiding predation, direct solar exposure, and evaporative water loss by remaining below the surface. The utilization of this microhabitat might enable this species to remain in the area of the pond until more favorable conditions exist for movement (i.e., rain events, higher humidity).

Observations of *R. a. draytonii* using this type of microhabitat are significant for several reasons: this species is federally listed as threatened by the U. S. Fish and Wildlife Service; *R. a. draytonii* occurs in areas where its aquatic habitat is often ephemeral; and lands upon which the species occurs might be managed and its aquatic habitat might be altered through dredging.

In the course of conducting U.S. Fish and Wildlife protocol-level surveys, observers should not assume that a recently dried pond signifies the absence of this species from the site. The importance of documenting the presence of this frog is vital to understanding the range of the species and in promoting the recovery of *R. a. draytonii.* In some cases, searching the deep cracks of recently dried ponds might reveal the presence of this frog.

Stock ponds, where this species might occur, are often dredged to remove built-up silt loads (pers. obs.). Typically, dredging oc-

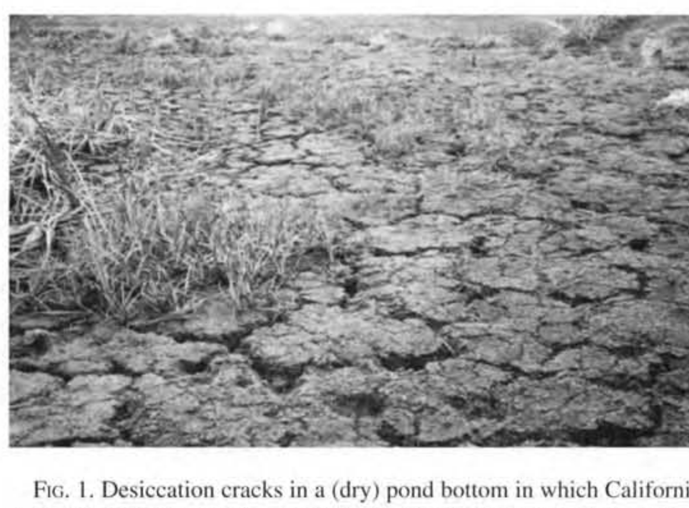

FIG. 1. Desiccation cracks in a (dry) pond bottom in which California red-legged frogs were observed utilizing as refugia in east Contra Costa County California.

curs after ponds have dried, following the assumption that frogs have retreated from the site. This practice might result in a high level of mortality to an already threatened species.

I recommend that biologists conducting surveys for *R. a. draytonii*, and land managers who may be dredging "dry" ponds, consider the use of this microhabitat by *R. a. draytonii.* Further, searching this microhabitat should be a part of investigations where there is a potential for the occurrence of *R. a. draytonii.*

I thank Andrea F. Zuur, Jennifer L. Alvarez, and the Contra Costa Water District for support and assistance with this investigation.

RANA AURORA DRAYTONII (California Red-legged Frog). **PREDATION**. Herein we report on predation of California Red-legged Frogs observed during the course of a radio-telemetry study at Point Reyes National Seashore, Marin County, California, USA.

Rana aurora draytonii is federally listed as a threatened species; hence, there is considerable interest in learning more about its ecology and life history. During January 2000, we had 19 *R. aurora* outfitted with radiotransmitters (Rathbun and Murphey 1996. Herpetol. Rev. 27:187–189). Two of these frogs were captured at a breeding pond on 12 Jan 2000, fitted with a transmitter, PIT tagged, and released at the capture site. On 14 Jan, both frogs were still present in the pond. On 18 Jan, we attempted to relocate the frogs and found that the signal was originating 400 m north of the pond, along a small, unnamed tributary to Olema Creek. As we approached the creek, a great blue heron (*Ardea herodias*) took flight. We noticed that the transmitter signal immediately changed, and after switching the receiver to the second frequency, confirmed that both transmitters were inside the heron.

The transmitters continued to function, and we were able to radio-track the heron for three days. During that time, the heron spent most of its time within 2 km of the breeding pond. On 24 Jan, we recovered both transmitters in a California blackberry (*Rubus ursinus*) thicket below a dead red alder (*Alnus rubra*) snag along Olema Creek, 1200 m from the pond.

The *R. aurora* were both adult males (6.5 cm SVL and 33.7 g; 7.4 cm SVL and 41.7 g). Because we did not observe the predation event, it is not possible to determine the time of day that the frogs were eaten. Normally, *R. aurora* are nocturnal, but it is not unusual to find a few *R. aurora* floating at the water surface or sitting on the bank during the middle of the day (pers. obs.).

There are no published reports of herons or other waterbirds feeding on adult red-legged frogs. The Recovery Plan for the California Red-legged Frog (*Rana aurora draytonii*) (U.S. Fish and Wildlife Service. 2002. Portland, Oregon) discusses predation, but it focuses on non-native predators such as fish and bullfrogs (*Rana catesbeiana*). The plan mentions Raccoons (*Procyon lotor*), Great Blue Herons, American Bitterns (*Botaurus lentiginosus*), Black-crowned Night Herons (*Nycticorax nycticorax*), Red-shouldered Hawks (*Buteo lineatus*), and garter snakes (*Thamnophis* spp.) as predators on adult *R. aurora*, but only the hawk predation is supported by a published report (Rathbun and Murphey, *op. cit.*).

RANA CAPITO (Florida Gopher Frog). **DEFENSIVE BEHAVIOR**. About 2100 h on 17 July 1970 I collected a small (60 mm SVL) gopher frog (*Rana capito*) in southern Leon County, Florida, USA. The frog, sitting in the mouth of a gopher tortoise burrow, immediately became rigid, bent its head downward while arching its back, and placed its hands up over its closed eyes, palms up. I could hold the rigid frog in my hand and flip it like a coin without causing it to abandon its rigid posture. More recently (1996–2003), I observed this same behavior on numerous occasions while handling *Rana capito* at a drift fence encircling a temporary pond in southern Leon County, Florida. Then, between 7 Feb and 4 March 2003, every one of 14 immigrating frogs displayed this behavior to varying degrees when I scratched its head with my fingernail.

The behavior described herein is similar to the "unken reflex" reported in *Boophis albilabris* (Andreone 2003. Herpetol. Rev. 33:300–301), but differs in some respects. In *R. capito* (Fig. 1), just the hands are raised over the head, the back is flexed upwards rather than downwards, and the head is bent down. No bright coloration is exposed nor is a release call or other sound emitted while individuals displayed this behavior. A bitter-tasting, frothy secretion possessing a musty smell was produced when the skin of the back or head was rubbed. The eye-covering behavior, musty smell, and bitter taste or tingling of the human tongue has been noted in wild caught specimens throughout the range of the species from southern Alabama, panhandle Florida, central Florida, Georgia, and North Carolina (Mark Bailey, Paul Moler, Richard Franz, John Jensen, Alvin Braswell, pers. comm.).

The unken reflex has not been reported for any species in the family Ranidae and no warning coloration or sounds are involved so the behavior described here may not be aposematic and might have evolved independently in *R. capito* for a specific purpose.

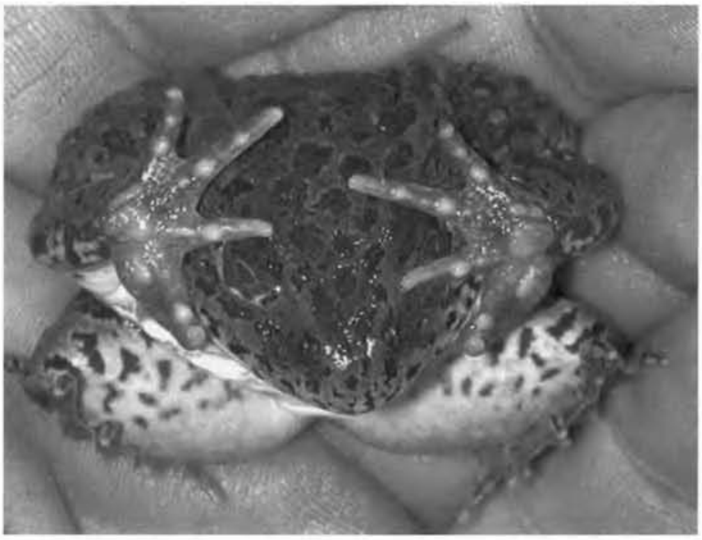

FIG. 1. Adult male *Rana capito* exhibiting "hands-up" defensive behavior. The body was so rigid that the frog could be held in an upright sitting position. Photographed in the field in southern Leon County, Florida.

One such purpose was suggested by observations made during the filming of a Gopher Frog in the presence of the Gopher Tortoise, *Gopherus polyphemus*, in an artificial burrow. I noticed that the frog, partially buried in sand, exhibited its "hands up," rigid-body posture when the much larger tortoise crawled over it at the bottom of the burrow. I was able to elicit the behavior by slapping the dorsum of a Gopher Frog, scratching its head with my fingernail, or pressing down on a frog's body with my hand. One function of this behavior might be to protect the Gopher Frog's eyes and dorsum from abrasion and sharp toenails.

CROCODYLIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **HOMING AND SITE FIDELITY**. Since the passage of the Lacey Act Amendment in 1969 and the Endangered Species Act in 1973, American alligator populations in Florida have increased substantially (Mazzotti and Brandt 1994. *In* Davis and Ogden, [eds.], Everglades: The Ecosystem and Its Restoration, pp. 485–505. St. Lucie Press, Delray Beach, Florida). Simultaneously, human populations and waterfront development have increased, leading to greater conflict between humans and alligators (e.g., Conover and Dubow 1997. Herpetol. Rev. 28:120–124). Several management options exist for resolving potential human-alligator conflicts, one of which is alligator translocation (e.g., Hines and Woodward 1980. Wildl. Soc. Bull. 8:234-241). However, homing by translocated alligators could negate the purpose of this management action. Juvenile alligators have been observed to home directly toward their origination site when displaced up to 10 home range diameters away, unless a major habitat barrier separated an alligator from its home site (Rodda 1984. Behav. Ecol. Sociobio. 14:241-246). Here, we augment the few data on homing following translocations with the report of an adult *A. mississippiensis* from southeastern Florida.

On 30 April 1998, we translocated an adult (2.2 m) female *A. mississipiensis* ca. 3.3 km straight-line distance from a pool on the North Fork of the Loxahatchee River (3-5 m average width) in Jonathan Dickinson State Park (JDSP; Florida) to a lake in the southwest corner of the park. The alligator was a breeding female and its pool was adjacent to human traffic, with harassing intrusions by humans being commonplace. The decision to move the alligator was based on human health and safety concerns, because she would aggressively defend her young from such (unlawful) intrusions. As required by Florida statutes, the capture and translocation of an alligator of this size was conducted by a nuisance alligator trapper (the senior author [JWW] herein) licensed by the Florida Fish and Wildlife Conservation Commission (license no. ATL 3725).

No direct waterways existed connecting the origination and relocation sites. Intervening habitat was comprised of a mix of pine-flatwoods, scrubby-flatwoods, and sand pine scrub. Eight days after translocation, the alligator was opportunistically observed in the same pool from which it had been moved. As the site of origin was not specifically monitored for the female's return, the 8 days is an upper bound on return time. Distinctive scars on its back, a missing right eye, and its size unmistakably identified this female, making it impossible to confuse with other individuals. The alligator remains in the same pool at this writing, and continues to breed annually.

The distance traveled by this alligator was not as remarkable as its ability to traverse the intervening terrain, and its ability to locate the same small pool from which it was removed. We were unable to discern the route of this animal's return to its site of origin. A water-based route would have required the female to "hopscotch" between small wet areas. However, Rodda (1984. Behav. Ecol. Sociobio. 14:241–246) observed juvenile alligators to chose direct routes towards their sites of origin, even when much easier indirect routes were available, supporting the hypothesis that alligators possess a directed navigational ability. Thus, given that no major topographic obstacles existed between the sites of origin and translocation, and the short span of time for this alligator to return, a direct return would seem logical. From a management perspective, translocation of alligators might not be successful unless a barrier to movement exists between the point of origin and translocation sites. Even if a barrier does exist, the intervening habitat near the translocation site should be evaluated to reduce the likelihood that an attempted return would place the animal in a position of conflict with humans, such as in a residential area. Hines and Woodward (1980. Wildl. Soc. Bull. 8:234–241) believed relocation to be the least economical and effective management approach for handling nuisance alligators. It might be warranted for select cases, but seems contraindicated as a general management tool.

LACERTILIA

AGAMA AGAMA (Red-headed Rock Agama). **NOCTURNAL ACTIVITY**. The broadly distributed anthropophilic African agamid *A. agama* is uniformly described as diurnal (Caxton-Martins and Nganwuchu 1978. J. Anat. 125:477–480; Spawls et al. 2002. A Field Guide to the Reptiles of East Africa. Academic Press, Natural World. 543 pp.). Harris (1964. The Life of the Rainbow Lizard. London, Hutchinson Tropical Monographs. 174 pp.) reported that the lizard's activity starts at sunrise and ends soon after sundown in Nigeria; the earliest activity time Harris reported was 0650 h. According to Ekundayo and Otusanya (1969. Niger. Fld. 34:83–90), activity at Lagos, Nigeria is maximal between 1000 and 1100 h, and is also high around 1800 h. Halstead (1970. Niger. Fld. 35:86–89) reported from Ife, Nigeria that activity starts, depending on the weather, between 0730 and 0830 h; between 1800 and 1900 h, they sluggishly retreat to rest. Here, we report activity in *A. agama* in the city of Mouila, Douya-Onoy Department, Ngounie Province, Gabon that is distinctly different from previ-

ous reports in being nocturnal.

On 15 November 2001, one of us (OSGP) noted a nocturnal activity by *A. agama* in the Quartier Dikongo near the Carrefour Barbier in the city of Mouila (01°52'07''S, 11°02'59''E; elev. 90 m). A group of 8 subadults (SVL ca. 70 mm) and adults (SVL ca. 110 mm) were observed from 2000 to 2300 h foraging for insects around the neon lights on an inhabited house. In this habitat, they were syntopic with 4 *Hemidactylus mabouia* (voucher specimen IRSNB 16211). The inhabitants of the house told us that these *A. agama* are active around the lamps year-round between dusk and 2330 h. We collected one (IRSNB 16210; subadult female; SVL 67 mm; 69 midbody scale rows) at 2300 h, when locals indicate that they are easiest to catch because they retire around that time. Its stomach was full of insects, mainly Coleoptera (Carabidae and Staphylinidae), Homoptera, Hymenoptera (Formicidae), and Lepidoptera. We observed night-active *A. agama* the same evening on 3 other lighted houses in the neighborhood.

These agamids were seen actively preying on insects, but they might also occasionally prey on *H. mabouia*. Gramentz (1999. Salamandra 35:193–208) reported a case of predation by *A. agama* on *Hemidactylus brookii*, but it occurred during the day. Why *A. agama* has not developed such a nocturnal activity around lamps in other and larger cities in Gabon like Libreville remains a mystery.

These observations were made as part of WWF Ecoregion Program-sponsored field surveys. We thank E. Mamfoumbi Kombila and M. Mpami (Direction de la Faune et de la Chasse, Libreville) for research and collecting permits, and J. Mayombo, R. Mikala-Mussavu and A. Pepy Boutolini (WWF-CARPO) for their kind help in the field. We are grateful to G. Lenglet and G. Coulon (Institut Royal des Sciences Naturelles de Belgique - IRSNB, Brussels) for processing our voucher specimens.

AMPHISBAENA DARWINII TRACHURA (Worm Lizard). **ALBINISM**. An adult male *Amphisbaena darwinii trachura* showing partial albinism (Prüst 1984. Litt. Serp. 4:6–15) was collected by M.A.A. da Silva on 11 Oct 1992 in the municipality of Cidreira (30°11'S, 50°12'W), on the coastal plain of Rio Grande do Sul State, southern Brazil. This is the first report of albinism in this species, and is to our knowledge the only reported incidence of albinism in amphisbaenids. The specimen, deposited in the herpetological collection of the Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP 4805), measures 271 mm SVL, and presents no other abnormalities in morphological, meristic, or morphometric data. When alive, its dorsal coloration was entirely white with a pinkish tinge, except for the markedly dark eyes, and scattered melanistic marks (Fig. 1). The belly was immaculate white. This report reinforces the prediction of Sazima and Di-Bernardo (1991. Mem. Inst. Butantan 53:167–173) who suggested, with regard to snakes, that additional instances

FIG. 1. Albino *Amphisbaena darwinii trachura* (MCP 4805), from Rio Grande do Sul, southern Brazil.

of albinism will probably continue to be found mainly among species with nocturnal or cryptozoic habits, or those otherwise protected against visually orientated predators.

Ipiranga, 6681, CEP 90619-900, Porto Alegre, RS, Brazil (e-mail: chalkidis@hotmail.com; madibe@pucrs.br).

AMPHISBAENA FENESTRATA (Virgin Islands Worm Lizard). **EVAPORATIVE WATER LOSS.** *Amphisbaena fenestrata* is endemic to the Virgin Islands of the Puerto Rico Bank. Like most members of its fossorial genus, it is rarely seen and thus little-known (Gans and Alexander 1962. Bull. Mus. Comp. Zool. 128:67–158). In the course of evaporative water loss studies on Virgin Islands squamates (e.g., Perry et al. 2000. Biotropica 32:722–728, and citations therein), we had the opportunity to test 3 *A. fenestrata*.

The 3 individuals examined were collected on Guana Island (18°38'N, 65°25'W), British Virgin Islands. All were found surface-active during the day following heavy rains. Collection sites were up to 70 m above sea level and had thick plant cover, providing protection from direct sunlight. Substrates varied from sandy to rocky loam. Total water loss was measured in the laboratory using the methods of Dmi'el et al. (1997. Biotropica 29:111–116). Animals were tested within 24 h of capture, having been maintained with ad lib water but no food. Following the study, animals were euthanized and deposited at the Yale Peabody Museum (YPM 12061: TL 214 mm, 5.0 g; YPM 12986: TL 181 mm, 2.5 g) and the Sam Noble Oklahoma Museum of Natural History OMNH 39481 (TL 197 mm, 3.1 g). The sex of these animals was not determined. We report water loss calculated two ways. First, we used mass to calculate water loss in mg g^{-1} h^{-1}. Our results were as follows: OMNH 39481 had the lowest water loss rate: 5.64 mg g^{-1} h^{-1}. The largest individual (YPM 12061) lost 5.99 mg g^{-1} h^{-1}, and the smallest animal (YPM 12986) had the highest water loss rate: 6.56

mg g^{-1} h^{-1}. We also calculated water loss per unit surface. To quantify surface area, we assumed an amphisbaenid is cylindrical in shape, and calculated surface area (A) from total length (TL, in mm) and average diameter (D, measured to the nearest 0.1 mm at three positions: just behind the head, at midbody, and just anterior to the cloaca), using the equation $A = p \cdot D \cdot TL$. We were unable to partition respiratory from cutaneous water loss, and thus used total water loss, which includes both. However, cutaneous gas exchange in amphisbaenians is especially large (Abe et al. 1987. J. Exp. Biol. 127:159–172), implying a relatively low breathing rate. We therefore expect water loss through the respiratory tract to be low as well, making our values only somewhat higher than actual cutaneous water loss rates. Our results were as follows (surface area and water loss rate, respectively, indicated for each): OMNH 39481: 32.2 cm^2, 0.55 mg cm^{-2} h^{-1}; YPM 12061: 44.3 cm^2, 0.66 mg cm^{-2} h^{-1}; YPM 12986: 26.2 cm^2, 0.62 mg cm^{-2} h^{-1}.

Few comparative data exist for amphisbaenians. Krakauer et al. (1968. Nature 218:659–660) graphed total water loss for 13 individuals. Of 7 species examined, 6 were comparable in size to *A. fenestrata*. These 6 species broke into two distinct groups based on habitat: humid or desert. However, the experimental design of Krakauer et al. (*op. cit.*) differed in that dried, flowing air was used rather than air at ambient humidity, preventing a precise comparison of results. Nonetheless, values for *A. fenestrata* seem most similar to the desert group, as might be expected from a species residing on a fairly dry island (Dmi'el et al. 1997. Biotropica 29:111–116).

We thank Kate LeVering and Marc Hayes for critically reading the manuscript, Arijana Barun, Tom Willard, and the staff of Guana Island for technical assistance, and Henry and Gloria Jarecki for access to Guana Island. CALEDONISCINCUS AUSTROCALEDONICUS (Common Litter Skink). **HERBIVORY.** Frugivory and nectivory in lizards, and their concomitant effects of seed dispersal and pollination, have begun to attract long overdue attention (Olesen and Valido 2003. Trends Ecol. Evol. 18:177–181; Perry and Lazell 1997. Herpetol. Rev. 28:150–151). Here, we add to this still relatively limited observation base with an observation of frugivory in common litter skink *Caledoniscincus austrocaledonicus* in New Caledonia.

On 23 January 2003, we visited islands in the Baie de Goro off the southeast coast of Province Sud, Grande Terre (22°15'S, 167°02'E). At ca. 1100 h on Ilot Kouaneak, and ca. 1500 h on Ilot Nie, we observed litter skinks eating the bright red berries of *Rivina humilis* (Phytolaccaceae). The fruits of this same plant are eaten by *Anolis* in the Caribbean (Lazell and Perry 1997. Herpetol. Rev. 28:150; Lazell and Mitchell 1998. Herpetol. Rev. 29:237). On both Kouaneak and Nie, litter skinks are hyper-abundant (densities reach 4 m^{-2}). Olesen and Valido (*op. cit.*) suggest that herbivory might facilitate unusually high lizard densities on islands, through density compensation and ecological release.

We thank Aaron Bauer and Ross Sadlier for introducing us to the wonders of New Caledonia, and Jonathan Kolby, Elisabeth Hills, and Greg Watkins-Colwell for field assistance. Voucher specimens were collected under permit 6034-346, Direction des Ressources Naturelles, Province Sud, whose staff was most helpful.

CHALCIDES THIERRYI PULCHELLUS (Cylindrical Skink). **ATTEMPTED PREDATION.** *Chalcides thierryi pulchellus* is a medium-sized (72–122 mm SVL) tan and brown terrestrial and semi-fossorial lizard that is native to West African woodlands and semi-arid bushlands (Schätti 1986. Revue suisse Zool. 93:765–778; Caputo et al. 1995. Trop. Zool. 8:95–152; Joger and Lambert 2002. Trop. Zool. 15:165–185). Although the diet of West African members of the genus remains unknown, North African *Chalcides* prey upon a broad range of invertebrates and small lizards, and cannibalism is suspected in *C. mionecton* and *C. ocellatus* (Schleich et al. 1996. Amphibians and Reptiles of North Africa. Koeltz Scientific Books, Koenigstein, Germany. 627 pp.). Herein, we report a predation attempt by *Chalcides thierryi pulchellus* upon a snake of the genus *Dipsadoboa*.

On 24 September 1984, Beat Schätti (*op. cit.*) collected an adult female (119 mm SVL) *Chalcides thierryi pulchellus* (MHNG 2235.1) under a rock in humid dense "Guinea Savanna" forest (Schätti, pers. comm.) at Naréna, Mali (12°13'60"N, 08°37'60"W; elev. 393 m). Examination of stomach contents from this specimen revealed a tail of a snake (Fig. 1). Lacerations at the proximal end of the tail suggest that it had recently been bitten off by the *Chalcides*. The tail is slender and 108 mm long; there are 62 single subcaudals with smooth slightly overlapping scales and a markedly expanded row of vertebrals following fusions with the paravertebral ones. Seven transverse scale rows exist at the proximal end of the tail, five transverse rows 16 subcaudals distal to this point, and three transverse rows 33 subcaudals from the proximal edge of the tail. The tail tip is missing. The dorsum and sides of the tail are brown to light brown with dark brown spots or blotches on the posterior and sides of some scales. Although dark blotches occur in the centers of some scales, no discernable pattern exists. The venter is immaculate cream. The internal tissues of the proximal end of the tail are partly digested, however, as no retractor penis muscles could be observed more distally, the tail probably originates from a female.

Identification of the tail to genus is possible because of the unusual combination of morphology, shape, length, and color; the presence of single subcaudals eliminates most African snake genera. The viperid genera *Atheris, Causus*, and *Echis* have keeled scales, and the maximum number of subcaudals for the actractaspidid genera *Atractaspis* and *Polemon* is only 32. Apart from some species of *Dipsadoboa*, the minimum number of

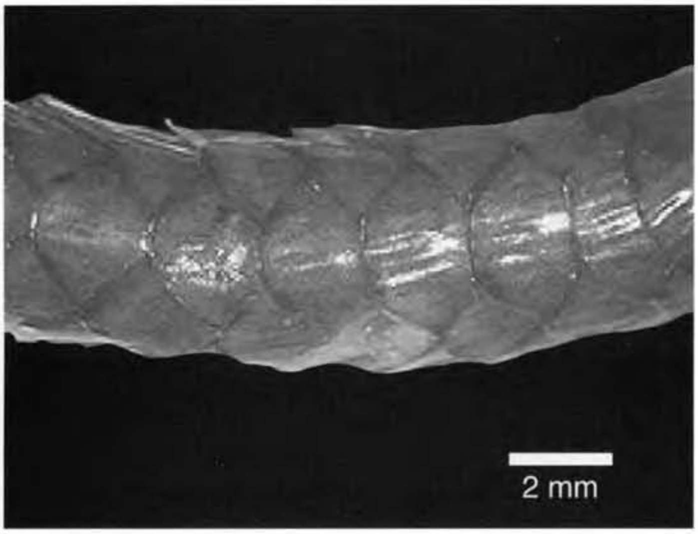

FIG. 1. Dorsal view of a section of the tail of an adult *Dipsadoboa* sp. removed from the stomach of an adult female *Chalcides thierryi pulchellus* from Naréna, Mali.

subcaudals falls within the range of *Lamprophis olivaceus* (38–63), *Aparallactus lunulatus* (41–65), and *A. niger* (33–64), but these taxa have black or gray dorsal tail coloration (Chippaux 1999. Les Serpents d'Afrique Occidentale et Centrale, IRD Éditions, Lyon, France. 278 pp.). Moreover, *Lamprophis olivaceus* has dark pigment on the ventrals and subcaudals (Pitman 1974. A Guide to the Snakes of Uganda, Wheldon and Wesley, London, UK. 290 pp.) and more (> 9) transverse scale rows at the proximal end of the tail (J. Rasmussen, pers. obs.). The maximum tail length of *Aparallactus lunulatus* (100 mm) is shorter than the tail fragment we describe, and *A. niger* has black pigment on the margins of its subcaudals (Witte and Laurent 1947. Mem. Mus. R. Hist. Nat. belge [ser. 2] 29:1–134.).

Thus, only the genus *Dipsadoboa* remains. Because both the proximal and distal ends of the tail are missing, the snake might be any of the four West African *Dipsadoboa* with single subcaudals: *underwoodi* (71–87 subcaudals), *unicolor* (52–78 subcaudals), *viridis* (68–103 subcaudals), or *weileri* (54–73 subcaudals). The transverse scale reduction is most consistent with *D. unicolor* whereas the tail coloration is most consistent with *D. underwoodi,* but these species are not known from Mali (Rasmussen. 1993. Steenstrupia 19:129–196; Joger and Lambert 1996. J. afr. Zool. 110:21–51; Chippaux, *op. cit.*). However, both species are known from tropical rain forest habitats and could have survived as relicts in the humid forest at Naréna.

We thank S. Fisch-Muller for permission to dissect the *Chalcides* specimen, B. Schätti for information about Naréna, A. Larson (FMNH) for comparative material, U. Joger for initial discussions, and L. Trueb for comments on the manuscript.

CROTAPHYTUS COLLARIS (Eastern Collared Lizard). **HOMING AFTER DISPLACEMENT.** Homing is known from distances > 500 km in sea turtles, and from 1–2 km in crocodilians and snakes. By contrast, homing over more than 200 m is rare in lizards, particularly in species that maintain territories (Zug et al. 2001. Herpetology: An Introductory Biology of Amphibians and Reptiles. Academic Press, San Diego, California. 630 pp.). I observed an unusual instance of homing back to an established territory by a displaced male collared lizard, *Crotaphytus collaris*, at Arcadia Lake Dam, Edmond, Oklahoma.

At this site, males establish territories on the boulder fields that line the north and south slopes of the 0.5-km long flood control spillway behind the dam (Baird et al. 2001. Ethology 107:15–32). During water release, a flowing (rate = 1 m/sec) 9.5-m wide channel separates these slopes. Lizards usually venture only to the water's edge, but when the outflow is closed, males sometimes make forays into the dry channel to pursue odonates. A uniquely paint-marked male that had defended a territory since 1 April 2001 on the eastern end of the north slope was apparently displaced when the outflow was opened at 0900 h on 17 June 2002. This male was re-sighted on the south slope at 1230 h that same day, but by 1030 h two days later he had returned to his original territory even though the spillway flow was not interrupted during this period.

Homing by a landward route would have required this male to travel at least 416 m west along the south slope, turn 90° to the north slope, and then turn again 90° eastward to travel 390 m back to his territory. Such a return route would have been > 800 m, and would have required his crossing through the territories of 7 other males. Alternately, he could have taken the most direct return route by swimming across the flowing channel while avoiding being swept over a waterfall that was 30 m downstream of where he was sighted on the south slope. Aquatic behavior in collared lizards has been reported, but simply involved diving into calm water at the edge of ponds to take refuge under rocks (Burt and Hoyle 1934. Trans. Kansas Acad. Sci. 37:193–216; McAllister 1983. Herpetol. Rev. 14:11). One day after his return, this displaced male disappeared and was not sighted subsequently despite daily systematic search of the study site through 15 July 2002. Sudden disappearance during the peak reproductive season strongly suggests that he died, possibly as a consequence of the high physiological costs associated with either the long overland migration or the strenuous swim.

This study was conducted under Oklahoma Department of Wildlife Conservation permit 3201 issued to Troy A. Baird.

EUMECES ELEGANS (Elegant Skink). **DEFENSIVE BEHAVIOR**. Amphibians and reptiles use numerous behaviors and mechanisms to avoid predation. Among lizards, bluff, crypsis, immobility, mimicry, retaliation, and tail autonomy are common behaviors that reduce the likelihood of predation. In contrast, diving into water and remaining submerged is a defensive behavior generally associated with aquatic amphibians, turtles and snakes, although selected lizards (e.g., some monitors, *Varanus* spp.) are

known to engage in this behavior (Mattison 1989. Lizards of the world. Facts on File, Inc., New York. 65 pp.; Zug et al. 2001. Herpetology an introductory biology of amphibians and reptiles. Academic Press. San Diego. 284 pp.). Here, we describe diving and submergence behavior in the elegant skink, *Eumeces elegans*.

At 1348 h on 8 February 2002, an adult (ca. 75 mm SVL) *E. elegans* of unknown sex, was seen moving over a patch of dry silt in an irrigation ditch in the agricultural area of Santzepu (23°25'42"N, 120°28'55"E), Shuisan District, Chiayi County, Taiwan. Conditions were sunny and warm (air temperature 28.7°C).

Initially, the skink tried to shelter among black-jacks (*Bidens pilosa* var. *radiata*) and horsetails (*Equisetum ramosissum debile*) partly covering the silt patch, but upon our further approach, the animal dove into the adjacent shallow (ca. 10 cm) pool. There it sought shelter among the rocks. The lizard's body was mostly concealed under a rock 13 cm wide x 16 cm long with its head and tail protruding from each end. After remaining in this position for ca. 10 seconds, the skink pushed its head above the water surface just enough to take a few breaths then retreated under the rock.

A water route was not the only escape option. The skink could have used a terrestrial escape route by running in either direction along the ditch, or fleeing to the edge of the ditch and running up the wall and out of the ditch. *Mabuya multifasciata*, introduced to southern Taiwan (Ota et al. 1994. Zoological Studies 33:86–89), has been observed to dive into water to escape capture both in captivity and in the wild (Chu 2000. Nature Conservation Quarterly Issue 29:50–53 [in Chinese]), but this behavior has not been observed in any other lizard species in Taiwan.

EUMECES LATICEPS (Broad-headed Skink). **PARASITES.** Blow (Diptera: Calliphoridae) and flesh (Diptera: Sarcophagidae) flies may opportunistically parasitize amphibians and reptiles. Flesh fly infestations have been reported in some turtles (e.g., *Graptemys pseudogeographica*, Vogt 1981. Copeia 1981:457–459; *Terrapene carolina*, references in Dodd 2001. North American Box Turtles, A Natural History. Univ. Oklahoma Press, Norman. 231 pp.), and Bleakney (1963. Can. Entomol. 95:107–108) noted blow fly parasitism on live American toads (*Bufo americanus*). Here, we add a report on an instance of blow fly parasitism on the broad-headed skink, *Eumeces laticeps*.

During a herpetological survey of the George Washington Memorial Parkway (National Park Service), Fairfax County, Virginia (38°57'57"N, 77°09'20"W; NAD 83) on 4 June 2002, we encountered an adult male *E. laticeps* (111 mm SVL) 2 m from the edge of the Potomac River clinging to the base of a 1.5 m diameter oak (*Quercus* sp.). The habitat is a mixed deciduous floodplain edge forest dominated by oaks (*Q. alba*, *Q. rubra*), beech (*Fagus grandifolia*), and tulip poplar (*Liriodendron tulipifera*). The *E. laticeps* had 4 puncture wounds on the head and neck (midventrally 2 mm anterior to the forelimbs, below the right jaw, in the right temporal region, and middorsally in the parietals; the dorsal wounds were 19 mm apart), and the tail had been severed at about mid-

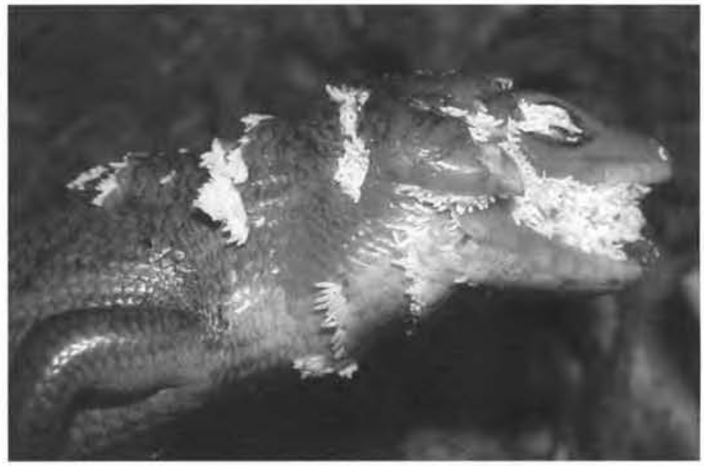

FIG. 1. Blow fly parasitism on *Eumeces laticeps* in Fairfax County, Virginia.

length. Approximately one dozen blow flies were laying eggs on the skink (Fig. 1). They were actively depositing ova in the lizard's mouth, eyes, nostrils, puncture wounds, and in the end of the broken tail. Fly ova were also found on the anterior surfaces of the rear limb insertions and between dorsal scale rows where no wounds existed. Close inspection revealed an approximate respiration rate of one breath every 10 seconds, suggesting to us that the lizard was stressed. When touched, the skink lunged weakly to the side in an attempted defensive bite despite having a mouth full of fly eggs. We believe that the lizard might have been injured during an unsuccessful predation attempt (possibly by a felid or mustelid) and subsequently parasitized by the flies. We euthanized the skink humanely but did not salvage it.

Our work in this national park was conducted under permit GWMP-2001-SCI-0002 to Thomas K. Pauley (Marshall University). We thank Art Evans (Richmond, Virginia) for help with fly identification.

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). **LONGEVITY.** In 1999, we initiated a population study of the introduced *Hemidactylus turcicus* on Smith Hall, a one-story brick building on the McNeese State University campus, Lake Charles, Louisiana, USA. Lizards were caught by hand, measured, weighed, and identified by unique toe-clip combinations. On 15 June 1999, we captured a male 56 mm SVL, making it a sexually mature adult because it exceeded the minimum adult size for males of 42–44 mm SVL (Selcer 1986. Copeia 1986:956–962; Punzo 2001. Florida Scientist 64:56–66). Male *H. turcicus* reach sexual maturity 8–9 months after hatching (Selcer, *op. cit.*; Punzo, *op. cit.*; pers. obs.), so this male must have hatched during or prior to the summer of 1998. We recaptured this male on 5 May 2002 (59 mm

SVL), so it survived 4 winters and was at least 4 years old.

On 14 June 1999, we captured a 49 mm SVL female, making it sexually mature because it exceeded the minimum female adult size (41.5–43 mm SVL; Selcer, *op. cit.*; Punzo, *op. cit.*). Because female *H. turcicus* also reach sexual maturity 8–9 months after hatching (Selcer, *op. cit.*; Punzo, *op. cit.*; pers. obs.), this female must also have hatched during or prior to the summer of 1998. We recaptured this female on 2 June 2002 (57 mm SVL), so it also survived 4 winters and was at least 4 years of age.

Longevity of these two *H. turcicus* exceeds the 3 year lifespan proposed by Selcer (*op. cit.*). Both were among the largest lizards we caught when they were captured in 2002, implying that 4 years might approach the maximum lifespan for this species.

Lizards were collected under the authority of Louisiana Department of Wildlife and Fisheries Scientific Collecting Permits LNHP-99-019 and LNHP-02-018 issued to Mark A. Paulissen.

MEYER**, Department of Biological and Environmental Sciences, McNeese State University, Lake Charles, Louisiana 70609, USA.

IGUANA IGUANA (Sinimbu, Green Iguana). **REPRODUCTION.** The iguanid *Iguana iguana* has a broad geographic distribution across Central and South America. In most South American countries, iguanas have significant socioeconomic importance in rural communities as a food resource (Divers 1995. Brit. Herpetol. Soc. Bull. 51:6–26). In Brazil, where the sinimbu has a distribution through the Amazon, the Pantanal and Caatinga, no information exists on the biology of the species in the wild. Here, I provide preliminary data on nests, nest colonies, densities, and reproduction for *I. iguana* from Pantanal habitat in southern Brazil.

This study was conducted on Paraguay River near the city of Corumbá, Mato Grosso Sul (18°59'S, 56°39'W; elev. 60 m) in November–December 1992, when iguanas lay eggs. Nests colonies were located, and I opened intact nests in order to count eggs and measure the dimensions (length and width) of 8–19 egg samples. I also captured females near the nests, measured them (SVL), and assessed their reproduction condition (gravid or not). I considered females gravid if they had an expanded abdominal cavity and had excavated nests, and non-gravid if they had a deflated abdominal cavity and were located within nest holes. Between 0900 and 1200 h on 18–20 January 1994, I also conducted an iguana census by boat that covered both banks of two stretches of the Paraguay River. Each stretch covered 4 km.

I located 6 groups of nests 3 to 300 m apart and a total of 18 nests over a 2-km length of river. Nests were located in clay river banks in open habitat within 3 m of the river margin. I saw females excavate nest holes with both their limbs and their mouth. At each nest group, nest holes were within 50 cm of one another. Each nest group had 3 nests with eggs; the remaining excavated holes appeared empty. Ten nests were predated, the other 8 were intact. Clutch size of intact nests averaged 14 (SD = 3.2, range: 12–19) and eggs averaged slightly over 1.4 times as long as wide (mean length 42.6 mm, SD = 1.7 mm; mean width 29.7 mm; SD = 1.3 mm). The vicinity of nests had many predated or rotten eggs. I observed Yellow Anacondas (*Eunectes notaeus*) three times near nests: twice with *I. iguana* eggs in their mouths and once in a hole near a nest colony. I captured 8 reproductive age female iguanas (4 gravid and 4 that had recently deposited eggs). These females were 31.0–39.5 cm SVL (mean 33.5 cm SVL, SD = 2.6 cm). During the riverbank survey, I recorded 3.5 iguanas/km in one stretch of the river, and 2.0 iguanas/km in other.

The aggregative behavior I describe for nesting *I. iguana* females along the banks of Paraguay River at the end of the dry season is similar to aggregative behavior for reproduction that has been observed on Barro Colorado Island in Panama, and in Venezuela (Rand 1968. Copeia 1968:837–842; Rodda and Grajal 1990. Amphibia-Reptilia 11:31–39). Aggregation might help maintain nest temperatures or facilitate defense against egg predators (Greene et al. 1978. J. Herpetol. 12:169–176). The dry-season nesting interval for iguanas in Panama (Rand 1972. Herpetologica 28:252–253) coincides with the seasonal pattern in the Pantanal. The clutch sizes of 12–19 I report for the Pantanal are generally smaller than most other reports. In Surinam, clutch size varied from 24 to 57 (Hoogmoed 1973. Biogeographica: Notes on the Herpetofauna of Surinam IV 4:419); in Panama from 9 to 71 (Rand 1984. Vertebrate Ecol. Syst. 10:115–122); and in Colombia from 14 to 70 (Muller 1972. Zoologische Beitrage NF 18:109–131). Generally lower clutch sizes might reflect the range margin conditions of my study areas.

I thank Procópio Ferreira for help in the field.

LEIOCEPHALUS CARINATUS ARMOURI (Northern Curly-tailed Lizard). **PREDATION.** Indigenous species preying on exotic herpetofauna in Florida might be an important source of mortality (Butterfield et al. 1997. *In* Simberloff et al. [eds.], Strangers in Paradise, pp. 123–138, Island Press, Washington, DC). The Little Blue Heron (*Egretta caerulea*) feeds mainly on small fish, invertebrates (mostly crustaceans), and small amphibians (Rodgers and Smith 1995. *In* Poole and Gill [eds.], The Birds of North America, Species Account No. 145, The Academy of Natural Sciences, Philadelphia, Pennsylvania and The American Ornithologists' Union, Washington, DC). Here, we report an observation of predation by the Little Blue Heron on *Leiocephalus carinatus armouri*, an exotic species in Florida (Weigl et al. 1969. Copeia 1969:841–842).

At ca. 1325 h on 19 February 2003, a hazy-sunny day with a temperature ca. 27°C, HTS observed a juvenile (white plumage) Little Blue Heron prey on a small (4–5 cm SVL) *L. c. armouri* on a concrete seawall in Martin County. This site is adjacent to the 1999 county record location (Hauge and Butterfield 2000. Herpetol. Rev. 31:53), but has been occupied since at least 1994 (Smith and Engeman 2002. Florida Field Nat. 30:132–133) and is at the northern end of a relatively contiguous 90 km surveyed range of this species (Smith et al., *in press*. International Biodeterioration and Biodegradation). The heron was foraging on top of the seawall using the "walk slow" behavior (Rodgers 1983. Colonial

Waterbirds 6:11–23), when it saw the lizard (also on top of the seawall) dart into a vertical crevice. In 10–15 seconds of slow approach, the heron waved its head and neck slowly in a wide side to side sweep. When it reached a position over the crevice, the heron plucked the lizard out with one strike and swallowed it in < 10 sec.

The event was noteworthy because it involved a juvenile wading bird foraging in a terrestrial situation and preying on the exotic *L. c. armouri*. Although the Little Blue Heron occasionally hunts on land, most time is spent methodically foraging in shallow water (Willard 1977. Condor 79:462–470; Rodgers and Smith, *op. cit.*). Although herons and egrets have been known to capture and consume exotic lizards in terrestrial situations (Franz 2001. Herpetol. Rev. 32:253), and *L. carinatus* has been the subject of other unusual predation events (Smith and Engeman, *in press*. Herpetol. Rev.), we know of no similar wading bird depredation reports for *L. carinatus* in the literature.

Submitted by **HENRY T. SMITH**, Florida Department of Environmental Protection, Florida Park Service, 13798 S.E. Federal Highway, Hobe Sound, Florida 33455, USA, and **RICHARD M. ENGEMAN**, National Wildlife Research Center, 4101 LaPorte Ave., Fort Collins, Colorado 80521-2154, USA (e-mail: Richard.m.engeman@aphis.usda.gov).

LEPIDOPHYMA FLAVIMACULATUM (Yellow-Spotted Night Lizard). **PLACENTOPHAGIA**. Placentophagia (consumption of placental tissues) is known from among a few of the live-bearing lizards that exhibit placental development, namely the Australian scincid genera, *Egernia* and *Tiliqua* (Greer 1990. The Biology and Evolution of Australian Lizards. Surrey Beatty & Sons, Sydney, 264 pp.), and the xantusiid *Xantusia vigilis* (Bellairs 1969. The Life of Reptiles. Vol. 2, The Weinfeld and Nicolson Natural History, London, United Kingdom, 307 pp.). Here, I augment the scarce data on placentophagia in squamates with observations of this behavior in the Neotropical xantusiid *Lepidophyma flavimaculatum*.

During June 2002, each of two female *L. flavimaculatum* of uncertain origin gave birth to 9 young. One captive for over a year, had never been in contact with a male. The second was gravid when acquired, and gave birth eleven days later. Parturition allowed opportunity to observe placentophagia. One of the first female's newborn pulled out the remains of unidentified extra-embryonic tissues joined by the umbilical cord to its abdomen, then ate it. The other neonates from each of the two females or the females themselves may have done the same because each was devoid of extra-embryonic tissue remains when I first had the opportunity to observe each one and no evidence of extra-embryonic tissues was been found in the terrarium.

Placentophagia reported in *Xantusia vigilis* involves the female (Bellairs, *op. cit.*). Only in the two Australian scincid genera *Egernia* and *Tiliqua* was placentophagia performed by neonates (Greer, *op. cit.*), so behavior might be more widespread among scincomorph lizards. Field data will be required to determine whether the neonate placentophagia observed here is typical or just a function of captive conditions. Litters of *L. flavimaculatum* vary from 2 to 6 (Telford and Campbell 1970. Copeia 1970:379–381), so the two clutch sizes of 9 are high, but this could also be a function of available food in captivity. Lastly, unless *L. flavimaculatum* has the capability of storing sperm for an extended period of time, the females on which I report here might be derived from one or two of several parthenogenetic populations in Costa Rica or Panama (Telford and Campbell, *op. cit.*; Bezy 1972. Contr. Sci. Nat. Hist. Mus. Los Angeles 277:1–29).

Submitted by **AURÉLIEN MIRALLES**, Département d'Ecologie et de Gestion de la Biodiversité, Laboratoire d'Anatomie comparée, 55 rue Buffon, Muséum National d'Histoire Naturelle, 75005 Paris, France; e-mail: amiral@mnhn.fr.

LEPOSTERNON MICROCEPHALUM (NCN). **PREDATION.** Data about the natural history of South American amphisbaenids are scarce, reflecting their fossorial habits (Dunham et al. 1998. *In* Gans and Huey [eds.], Biology of the Reptilia, Volume 16 (Ecology B): Defense and Life History, pp. 441–522. Alan R. Liss, Inc., New York). In particular, few data exist on the predators of *Leposternon microcephalum*, an amphisbaenid widely distributed across South America (Peters and Donoso-Barros 1970. U. S. Nat. Mus. Bull. 297: 293 pp.). Fossorial snakes of genus *Micrurus* and some elapomorphines seem to be important predators of the amphisbaenid genus *Leposternon*, but some bird and mammal predators have also been reported (Marques and Sazima 1997. Herpetol. Nat. Hist. 5:88–93; Zamprogno and Sazima 1993. Herpetol. Rev. 24:82–83). As the omnivorous South American coati (*Nasua nasua*: Procyonidae) is not among reported predators, we report coati predation on *L. microcephalum*.

During a herpetological survey in the conservation area of Parque Florestal do Rio da Onça, Matinhos Municipality, Paraná, Brasil (25°45'–25°50' S; 48°30'–48°35' W; Coastal Atlantic Forest, restinga habitat) from April 1999 to April 2000, we observed a free-ranging but human tolerant 1-year old female *N. nasua* preying on *L. microcephalum* 17 different times. Each *L. microcephalum* was located by sniffing the litter or sand substrate (a behavior that *Nasua narica* displays constantly; Kaufmann 1962. Univ. California Publ. Zool. 60: 95–222), digging with the snout, capturing the prey with mouth and forepaws, and ingesting it in pieces immediately after the capture. Only 4 of 17 *L. microcephalum* were completely eaten. The other 13 were abandoned after being partially eaten, and are deposited in the herpetological collection of Museu de História Natural Capão da Imbuia, Curitiba, Paraná, Brasil (MHNCI 9688–9694, 9705–9710). In four of these individuals, the head and anterior part of the trunk were eaten; in seven others, the posterior third of the body was eaten; both ends of remaining two were eaten.

Nasua nasua has a broadly generalized diet that include flowers, fruits and small invertebrates often taken from epiphytic bromeliads or on the ground (Beisiegel 2000. Braz. J. Biol. 61: 689–692) as well as anurans and crustaceans (M. Oliveira, E. R. Ribas, pers. obs.). A crab-eating fox (*Cerdocyon thous*) was the only mammal reported to prey on the related *Leposternon wuchereri* (Zamprogno and Sazima, *op. cit.*), but this is the first record of *N. nasua* predation on any amphisbaenid.

The Ambiental Institut of Paraná provided the permit to Mitzi Oliveira that enabled survey in the Parque Florestal do Rio da Onça conservation area.

Submitted by **MITZI OLIVEIRA**, Museu de Ciências Naturais da Universidade Federal do Paraná, Centro Politécnico, Jardim das Américas, Caixa Postal 19.031, CEP 81531-990, Curitiba, Paraná, Brasil (e-mail: mianolis@hotmail.com), **ELIS REGINA RIBAS**, Museu de Ciências Naturais da Universidade Federal do Paraná (e-mail: elisrr@rc.unesp.br), and **JÚLIO CESAR DE MOURA-LEITE**, Laboratório de Herpetologia, Museu de História Natural Capão da Imbuia, Departamento de Zoológico, Rua Prof. Benedito Conceição, 407, CEP 82810-080, Curitiba, Paraná (e-mail: mleit@uol.com.br).

LIOLAEMUS SANJUANENSIS (NCN). **BODY TEMPERATURE.** *Liolaemus sanjuanensis* is a lizard endemic to the Sierra de Pie de Palo, an old 60 x 30 km cordillera in Western Argentina with geologic history different from the Andes. *Liolaemus sanjuanensis* has an ambiguous conservation status, as it has been defined as a species for which "insufficient knowledge" exists (Lavilla et al. 2000. Categorización de los anfibios y reptiles de la República Argentina. Asoc. Herp. Arg., San Miguel de Tucumán, Argentina. 97 pp.). Data on its biology are sparse. Marinero et al. (2002. Actas XVI Reunión de Comunicaciones. La Plata. [www.fcnym.unlp.edu.ar/xvirch]) and Buff et al. (2002. Actas XVI Reunión de Comunicaciones. La Plata.) made observations on its reproduction and morphology based on relatively few lizards (N = 29), providing the only published data on this species' biology. Here, we present the first data addressing the species' thermal ecology.

We conducted field work in the Sierra de Pie de Palo, Departamento Angaco, Provincia de San Juan (31°22'S, 67°58'W) on 8–9 December of 2001. Data are based on 29 captures made between 1100 and 1400 h in the Altoandina Phytogeographic Province over an elevation range of 2870–2994 m. The flora, largely Andean, is dominated by needlegrasses (*Stipa*) with patches of various forbs, with the genera *Fabiana*, *Baccharis*, *Adesmia*, and *Senecio* being important (Cei 1980. Hist. Natural. 1:137–140). To collect data, we revisited a randomized selection of bushes and low rocks across the study site. Each individual was captured by hand. The cloacal (TC), substrate (TS) and air (TA) temperatures were measured (to nearest 0.1°C) with a rapid reading Miller-Weber thermometer. For each capture, we took TS at the exact point of observation, and TA 1 cm above the substrate.

Mean body temperature of 29 *L. sanjuanensis* was 30.1°C (s = 3.2°C). Body size was negatively associated with TC ($r = -0.46$, $P = 0.01$). An ANCOVA (body size as the covariate) revealed no inter-gender differences in TC ($F_{2,25} = 0.81$, $P = 0.45$). An ANOVA revealed significant differences between TC and TA ($F_{2,66} = 9.93$, $P < 0.01$) and TA and TS ($F_{2,66} = 9.93$, $P < 0.01$). Cloacal temperature and TS differences were not significant ($F_{2,66} = 9.93$, $P = 0.99$). Cloacal temperature and each of TS and TA were correlated ($r = 0.40$, $P = 0.03$; $r = 0.46$, $p = 0.01$, respectively)

Our data suggest that *L. sanjuanensis* thermoregulates behaviorally in a manner similar to *L. wiegmanni* (Martori et al. 1998. Rev. Esp. Herp. 12:19–26), *L. olongasta* (Cánovas et al. 2001. V Congreso Arg. Herp. pp. 32–33) and *L. koslowsky* (Martori et al. 2002. Cuad. Herp. 1:78–99). These species actively thermoregulate by moving among microhabitats having different temperatures, and differ from *L. pseudoanomalus* (Villavicencio et al. 2001. IV Congreso Arg. Herp. pp. 81–82), an apparent thermoconformer that appears to have body temperatures that closely track substrate and air temperatures.

Submitted by **JUAN CARLOS ACOSTA, RICARDO BUFF, JOSE ALBERTO MARINERO** and **PABLO GOMEZ**, Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina; e-mail (JCA): jcacosta@sinectis.com.ar.

PRISTIDACTYLUS SCAPULATUS (NCN). **DIET.** *Pristidactylus scapulatus*, one of six species in its genus in Argentina (Cei et al. 2001. J. Herpetol. 35:597–605), is thought to be widespread in the high Andes from north of San Juan in San Guillermo Provincial Reserve to Chubut Province (Cei 1986. Museo Regionale di Scienze Naturali Torino. Monografie IV. Torino, 527 pp.). However, its conservation status is ambiguous as it is defined as a species for which "insufficient knowledge" exists (Lavilla et al. 2000. Categorización de los anfibios y reptiles de la República Argentina. Asoc. Herp. Arg., San Miguel de Tucumán, Argentina, 97 pp.). *Pristidactylus scapulatus* has been considered insectivorous, but its biology is poorly known largely because it occurs at relatively low densities (Cei, *op. cit.*). Of the 6 *Pristidactylus* species that occur in Argentina, only *P. achalensis* (an endemic to the Pampa de Achala in Cordoba Province of central Argentina) is mentioned as being herbivorous, eating alternatively leaves and flowers (Etheridge and Williams 1985. Breviora 483:1–18). Here, we provide preliminary data on the diet of *P. scapulatus*, indicating that it can be frugivorous.

Our observations were based on data from 3 individuals. One, an adult female (96 mm SVL) was collected on 15 February 2002 north of El Leoncito National Park (31°45'S, 69°10'W; elev. 3100 m), Calingasta Department, on rocky slopes in the Puna Zone. Here, *Lobivia formosa*, *Lycium scleitery*, *Lycium chanar*, *Ephedra breana*, *Fabiana denudata*, and *Stipa* spp. dominated the vegetation. We collected the remaining 2 individuals, an adult male (103 mm SVL) and a juvenile female (49 mm SVL) on 23 April 2002 in Don Carmelo Multiple Use Reserve (31°10'S; 69°46'W; elev. 3000 m), Ullum Department, San Juan Province, also in the Puna Zone. Here, *Stipa speciosa var. breviglumis*, *L. chanar*, *Artemisia mendozana*, *Ephedra breana*, and *Maihueniopsis glomerata* dominate the vegetation. The lizards were taken to the laboratory, where they defecated and their feces were examined with a magnifying lens. Although we generally analyzed the samples qualitatively because of variation in disintegration of the fecal materials, we estimated the percentage (by volume) of plant and animal material.

About 90% of the feces consisted of *L. chanar* and *E. breana*, but fruits and seed of *L. chanar* were particularly conspicuous. The remaining material consisted of beetle (Coleoptera) parts from scarabs (Scarabaeidae) and darkling beetles (Tenebrionidae). We found the fruits of *L. chanar* and *E. breana* in the feces to be in various stages of digestion. Whole fruit as well as partialy digested fruit and seeds were present.

Similar partial digestion, in this case of flowers and leaves, is also found in diet of *P. achalensis* (R. Martori, pers. comm.). This

pattern of digestion may indicate that extraction of water and sugar is more important in *P. scapulatus* frugivory than the extraction of other materials from fruits. *Lycium chanar* and *E. breana* are distributed from Bolivia south to north of Mendoza, Argentina (Carretero 1995. Bol. Soc. Argent. Bot. 31:27–40). Both species occupy patches associated with rocky slopes in Puna Zone habitats in San Juan. *Lycium chanar*, the more abundant and widespread species, bears fruit from late January to April (J. Márquez, pers. comm.), and provides a dense thorny structure that may provide important cover from predators for *P. scapulatus*. Given the aforementioned pattern of frugivory, the importance of this lizard in seed dispersal deserves investigation.

Submitted by **JUAN CARLOS ACOSTA, GRACIELA BLANCO, FERNANDO MURÚA, JUSTO MÁQUEZ, JOSÉ VILLAVICENCIO,** and **GABRIELA CÁNOVAS,** Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina (e-mail [JCA]: jcacosta@sinectis.com.ar).

STENOCERCUS AZUREUS (NCN). **REPRODUCTION**. Few data exist on the reproductive biology of the tropidurid *Stenocercus*. Clutch size is known for fewer than half of the species. Two eggs have been reported in all species to date except *Stenocercus humeralis*, for which 4 eggs were recorded (Torres-Carvajal 2000. Univ. Kansas Mus. Nat. Hist. Sci. Pap. [15]:1–38). Here, I report on a second species of *Stenocercus* with a clutch size >2.

Upon examination of a radiograph, a 67 mm SVL female *S. azureus* (AMNH 17013) was found to contain 6 large eggs occupying about half the body volume. Using the formula for a prolate spheroid, the volume of these eggs was determined to average 451 mm^3 (range: 349–593 mm^3).

I thank Richard Etheridge for providing radiographs, and Jennifer B. Pramuk and Chris A. Sheil for reviewing this manuscript.

Submitted by **OMAR TORRES-CARVAJAL**, Division of Herpetology, KU Natural History Museum and Biodiversity Research Center, 1345 Jayhawk Boulevard, Lawrence, Kansas 66045-7561, USA; e-mail: otorres@ku.edu.

TAKYDROMUS HANI (Green Grass Lizard). **NATURAL HISTORY**. In the recent description of the lacertid *Takydromus hani*, Chou et al. (2001. Herpetologica 57:497–508) reported that the species, including the paratype (IEBR-L100), occurred in "undergrowth by streams in primary subtropical forests." Herein, I correct information in Chou et al. and report additional observations that suggest the species is primarily a tree-canopy inhabitant.

The paratype IEBR L100 (American Museum of Natural History [AMNH] Field Series 14140; collected by Darrin Lunde [AMNH] and D. Kizirian) was captured after it dropped from the tree canopy onto equipment in camp at 200 m elevation on a tributary of the Rao An, Huong Son Reserve, Ha Tinh Province, Vietnam (18°21'N, 105°13'E). An additional specimen (AMNH R147115) from the same locality, but excluded from the original description, was also captured after it dropped from the canopy onto David Grimaldi (AMNH). Despite exhaustive fieldwork by ca. 20 biologists within 1 km of the above locality over 32 days (19–22 April 1998, 4–22 May 1998, 16–24 April 1999), < 5 individuals of this species were observed, all of which dropped from the canopy and immediately ran up the trunks of large trees back into the canopy. All *Takydromus hani* were observed only in camp, which may reflect their preference for riparian forest or a sampling bias associated with the location of the campsite.

Specimens were collected with permission from the Vietnam National Centre for Natural Sciences and Technology, Hanoi and exported (Export Certificate No. 102-98) with permission from the Forest Protection Department, Ministry of Agriculture and Rural Development, Hanoi, Vietnam and the CITES management authority of Vietnam.

TEIUS OCULATUS (Green Lizard). **HATCHING AND CLUTCH SIZE.** The teiid *Teius oculatus* occurs in southern Brazil, eastern Paraguay, Argentina and Uruguay (Cei 1993. Monogr. XIV. Mus. Reg. Sci. Nat. Torino, 940 pp). The species is widespread in Rio Grande do Sul State in southern Brazil and is common in grassland habitats. Beyond limited information on a September–March seasonal activity, data on the ecology and natural history of this diurnal terrestrial lizard is scarce (Lema 1994. Com. Mus. Ci. PUCRS 7:41–150; Bujes and Krause 1999. Biociências 7:41–45). Notably, data are lacking on hatching size. Martori and Acosta (1990. Cuad. Herp. 5:15–18) classified individuals of this species that were 35.0–59.0 mm SVL as juveniles, but did not mention hatchlings. Hence, we provide preliminary information on hatchling and clutch size for *T. oculatus* from southeastern Brazil.

On 8 and 21 December 2002, during a study on the ecology of *T. oculatus* at Fazenda Chapada (30°25'23.5"S, 52°18'41.4"W), Serra do Sudeste, Rio Grande do Sul State, we collected two gravid females that were kept at ambient laboratory temperatures and provided *ad libitum* food. On 11 December 2002, the first female (103.3 mm SVL, 188.0 tail length [TL]) we collected deposited a clutch of 6 eggs (mean long axis length (LAL) = 16.9, 0.23 mm SD; mean mass = 0.8, 0.04 g SD). After 71 days, 3 hatchlings hatched from eggs (mean SVL = 39.4, 0.87 mm SD; mean mass = 1.4, 0.11 g SD). On 4 January 2003, the second female (105.1 mm SVL; 202.0 TL mm; 32.7 g) deposited five eggs (mean LAL = 16.9, 0.48 mm SD; mean mass = 0.93, 0.12 g SD); but these never developed. This female weighed 23.6 g after oviposition.

The hatchling sizes we found are similar to those for the smallest individual reported in the congeneric *T. teyou,* which was considered a neonate (Cruz et al. 1999. J. Herpetol. 33:420–429). The clutch sizes we found in *T. oculatus* (5 and 6 eggs) agree with Blanco and Acosta (1998. Bol. Soc. Biol. Concepción 69:33–38), who indicated a range of 2–8 eggs/clutch among *T. oculatus* from Cordoba Province, Argentina. These authors found that a larger proportion of gravid females in early December; in late December, only post-reproductive females were recorded. Our data suggest that the oviposition interval in *T. oculatus* from the Serra do Sudeste may be longer than that which Blanco and Acosta (1998,

op. cit.) report. Data on the second female suggests that reproductive effort in *T. oculatus* represents about one sixth of female body mass.

Voucher specimens (female and hatchlings) were deposited in the herpetological collection of the Museu de Ciências e Tecnologia da Pontifícia Universidade Católica of Rio Grande do Sul (MCP 14359, 14381–83). We thank Arlete Ballestrin Outeiral and Custódio de Almeida for permission to work on the Fazenda Chapada, and CAPES for financial support to LHC.

TROPIDURUS TORQUATUS (Collared Lizard, Calango) **SAUROPHAGY.** Saurophagy, often opportunistic behavior among lizards (e.g., Kiefer 1998. Herpetol. Rev. 29:41), may involve feeding on conspecifics (cannibalism), as in *Mabuya frenata* (Vrcibradic and Rocha 1996. Herpetol. Rev. 27:201–202) and *Tropidurus montanus* (Kiefer and Sazima 2002. Herpetol. Rev. 33:136) or feeding on heterospecifics (e.g., *Mabuya agilis*: Vrcibradic and Rocha 1995. Herpetol. Rev. 26:129–131; *Anolis sagrei*: Campbell and Gerber 1996. Herpetol. Rev. 27: 200). Here, we provide two reports of *Tropidurus torquatus* (Tropiduridae) preying on *Hemidactylus mabouia* (Gekkonidae) from southeastern Brazil.

Our observations were made in a residential area in Contagem municipality, State of Minas Gerais (19°55'S, 43°56'W). We made observations of two different individuals of *T. torquatus*; when first sighted, each was carrying a dead *H. mabouia* adult lengthwise and head first in its jaws. The first observation occurred at ca. 1400 h on 12 December 2000 when we saw an adult male (ca. 130 mm SVL) *T. torquatus* 170 cm high on a brick wall trying to swallow a dead adult (ca. 50 mm SVL, unknown sex) *H. mabouia*. The second observation occurred on 24 June 2001 at ca. 1300 h on the same wall 10 m away from the previous observation. Here, another adult (ca. 60 mm SVL, unknown sex) *H. mabouia* had also been captured, but in this case a female *T. torquatus* (ca. 100 mm SVL; also on the wall, but ca. 200 cm above ground) was shaking its prey while carrying it. In each case, we observed the respective *T. torquatus* for a ca. 10-min period until it ran out of sight into a crown of a tree. Our observations imply that other lizards may constitute alternative prey for *T. torquatus*.

We thank Marc P. Hayes for offering helpful suggestions on previous versions of this manuscript. This work was completed while CABG was supported by a graduate fellowship from CAPES and MVS had a research grant from CNPq.

TUPINAMBIS MERIANAE (Tegu Lizard). **FUNGIVORY.** Tegu lizards (genus *Tupinambis*) are generalist consumers with a diet based on diverse vertebrates (fishes, amphibians, reptiles, birds, and small mammals) and invertebrates (millipedes, arachnids, insects, and mollusks), as well as seeds, fruits, eggs, and carrion (Dessem 1985. Copeia 1985:245–247; Donadio and Gallardo 1984. Rev. Mus. Ciênc. Nat. Bernadino Rivadavia 13:117–127; Keifer and Sazima 2002. Amphibia-Reptilia 23:105–108; Martuscelli and Olmos 1996. Herpetol. Rev. 27:21; Mercolli and Yanosky 1994. Herpetol. J. 4:15–19; Milstead 1961. Copeia 1961:493–495; Sazima and Haddad 1992. *In* Morellato [ed.], História natural da Serra do Japi, pp. 212–236. Editora da Unicamp, Campinas, Brazil; Rivas et al. 2001. Herpetol. Rev. 32:108; Souza et al. 2002. Herpetol. Rev. 33:209). However, fungivory is unreported. Hence, we provide an observation of the tegu, *T. merianae*, feeding on mushrooms.

On 2 December 2002 around 1200, we observed a subadult (ca. 28 cm SVL) male *Tupinambis merianae* feeding on the fruiting body (mushroom) of the basidiomycete, *Macrocybe praegrandis*, growing on a lawn on the *campus* of the Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil. The lizard was seen taking a small bite atop one of three fruiting bodies available; it ate half the fruiting body (15 cm in diameter) in less than a minute. The lizard readily ingested the mushroom and showed no apparent sign that would suggest distastefulness. However, the lizard fled just after noticing the observer, which occurred after 20 sec of observation. This individual is part of a group of about a dozen free-ranging, semi-tame tegus that live on the University grounds. These lizards receive no other management beyond occasional food supplementation that consists of one-day-old chicks and bananas. Over the 14-day period during which the fruiting body of this fungus persisted, no other feeding episode was recorded, even though disappearance of more of the fruiting body implied continued consumption.

To our knowledge, among reptiles (in the historic paraphyletic sense), only tortoises of the genus *Kinixys* are known to regularly consume fungi (Hailey et al. 1997. J. Trop. Ecol. 13:469–474), although trace amounts of fungi are recorded in the diet of *Gopherus agassizii* (Hansen et al. 1976. Herpetologica 32:274–251). Thus, our observation may represent the first record of fungivory in a squamate reptile. Our observation of fungivory could reflect either atypical ingestion by a naive animal, or inclusion of previously unrecognized food item that may be difficult to identify from stomach content analysis. As no other tegus were seen feeding on this mushroom after the initial observation, the former alternative is most likely.

We thank Marina Capelari for the specific identification of the mushroom, Augusto S. Abe and Marc P. Hayes for kindly revising the manuscript. Fungi voucher material (DZRC 1002) was deposited in the collection of the Department of Zoology, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil. CNPq graduate

fellowships supported LFT and CPAP, and FAPESP supported DVA.

UMA EXSUL (Coahuila Fringe-Toed Lizard). **BURROWS.** For sand-swimming members of the genus *Uma,* burial in loose soil is both the typical refuge from predators and a thermoregulatory tactic (Pough 1969. Comp. Biochem. Physiol. 31:868–884; Pough 1970. Copeia 1970:145–157; Pough et al. 1978. Copeia 1978:81–86; Gadsden et al. 2001. Boletín Soc. Herpetol. Mexicana 9:51–66). Some of these authors mention the use of rodent burrows by *U. exsul*, but burrow creation in the genus *Uma* has only recently been recognized. Gadsden et al. (*op. cit.*) first detected the presence of *U. paraphygas* burrows during a study in Chihuahua (Mexico) in 1999 and subsequently noted the same for *U. exsul* at Coahuila. Here, we quantify the relationship between the seasonal density of *U. exsul* and their burrows in southwestern Coahuila, Mexico.

We conducted field work in the sand dune systems of the Mapimian subprovince of the Chihuahuan Desert in the dry Laguna de Viesca in southwestern Coahuila. We examined the seasonal density of *U. exsul* and their burrows in two populations (Gabino Vázquez = A, Saucillo = B) during fall 2000 and spring 2001. The two study plots were located on independent sand dunes separated by 10 km. Each 2 ha study plot was subdivided into 400-m^2 square quadrats (Tinkle and Ballinger 1972. Ecology 53:570–584; Tinkle and Dunham 1986. Copeia 1986:1–18). We flagged each burrow to avoid double counting, and conducted one burrow count in each season sampled. Lizard density was calculated based on Gadsden et al. (*op. cit.*). The lizards were caught with a noose, and were permanently marked by clipping two toes, one per foot (Tinkle and Dunham, *op. cit.*). Finally the toe-clip number was painted on the dorsal side with black, fast-dry enamel and the lizards were released at the site of initial observation (Turner and Schwalbe, 1986. Final Report. Arizona Game and Fish Department Heritage Fund. IIPAM Project No. 195042. 78 pp.). How frequently the areas were censused each day depended on number of lizards previously marked. Generally, the first census required four days, during which virtually all of the lizards observed were unmarked and had to be captured. With each succeeding pass, the number of new individuals decreased and re-sightings increased, allowing more passes per day. Generally, most adults were captured in the early censuses, whereas juveniles tended to be captured towards the tail of census intervals. After each complete pass, the number of new individuals captured was added to the total from all previous passes, giving an estimate of the total present for each of the two populations (Cuellar 1993. Bull. d'Ecologie 24[2–4]:109–149).

We used a Pearson correlation coefficient to assess the relationship between burrow and lizard densities, using data from each season in each of the two populations as separate data points.

We counted a total of 173 burrows (123 in fall, 50 in spring) and a total of 122 lizards (86 in fall, 36 in spring). In population A, we counted 20.5 burrows/ha and 15 lizards/ha in the fall; and 13 burrows/ha and 9 lizards/ha in the spring. In population B, we counted 41 burrows/ha and 28 lizards/ha in the fall, and 12 burrows/ha and 9 lizards/ha in the spring.

We found the densities of *U. exsul* and their burrows to be strongly correlated ($r^2 = 0.998$, $P = 0.001$, $N = 4$). Albeit limited, these preliminary data suggest that burrow density may be a useful indicator of lizard density for this protected endemic species (SEMARNAP 2000. Diario Oficial de la Federación (16 octubre), México, D. F., México.).

We thank Hugo López Corrujedo for fruitful discussions on this topic and suggestions on the manuscript.

SERPENTES

AGKISTRODON CONTORTRIX (Copperhead). **MAXIMUM PREY SIZE**. On 22 March 2003 at approximately 1100 h, we observed a juvenile Copperhead swallowing a large Cotton Mouse (*Peromyscus gossypinus*) in the Kisatchie National Forest of western Louisiana, USA. The snake's jaws and skin appeared to be stretched to their limits as they reached the posterior end of the mouse. The snake weighed 62 g and the mouse weighed 46 g, which represented a prey weight ratio (WR) of 74%. This prey animal was considerably larger than the mean prey WR of 18.5% and may exceed the largest prey WR of "over 50%" reported by Fitch (1960. Univ. Kansas Publ. Mus. Nat. Hist. 13:85–288).

We thank Paul Leberg and Alan Hitch for help identifying the mouse.

AUSTRELAPS SUPERBUS (Australian Copperhead) and ***EGERNIA SAXATILIS*** (Black Rock Skink). **PREDATION**. There are relatively few observations of predation events by snakes in the field. Here I report on ambush predation of a Black Rock Skink (*Egernia saxatilis*) by the Australian Copperhead (*Austrelaps superbus*). The observation occurred in the Kanangra-Boyd National Park, Blue Mountains, New South Wales (GR 150003'E, 33058'S) in an area vegetated primarily by Snow and Mountain Gums (*Eucalyptus paucifora, E. dalrympleana,* and *E. macarthuri*)

and Alpine snow grass (*Poa sieberana*). While observing *E. saxatilis* as part of another study, an individual of *A. superbus* was noted basking under a fallen *Eucalyptus* branch. The area of the branch over the snake was raised 5–10 cm above the ground. The snake (~1.5 m TL) was basking in an S-shape with its coils exposed on both sides of the branch and its head hidden beneath the branch. An individual of *E. saxatilis* was observed moving along the ground using the branch for overhead cover, and it ran along the body of the snake from the tail to and over the snake's head. The snake struck the lizard and grabbed its mid-body. The snake had a firm grip on the skink for ca. 2 min. At that point, I pried the snake's jaws open in order to retain a radio-transmitter implanted in the skink. As the skink was alive at the time, I brought the skink back to Sydney and kept it housed in a terrarium. For the next few days the skink could barely move, after which it started recovering and eventually was released. It was found alive in the field and apparently healthy 9 months later.

Because *A. superbus* is generally assumed to be an active forager (Shine 1987. J. Herpetol.21:21–28), it is possible that the snake simply took advantage of an opportunity while basking and was not actually waiting in ambush for prey. Furthermore, not only does this observation document a predation event in the wild but it also provides an interesting anecdote about the effect of venom on a prey item. It is highly unlikely the skink would have escaped from the snake, or even survived in the wild if it had. Irrespective of this, the present skink was in the snake's mouth for about 2 min and presumably was envenomated during this time; the venom was not lethal nor did the skink appear to suffer any obvious long-term effects of the encounter.

Submitted by **DAVID E. O'CONNOR,** Biological Sciences A08, University of Sydney, New South Wales 2006, Australia (e-mail: doconnor@bio.usyd.edu.au).

BOA CONSTRICTOR (Boa Constrictor). **DIET**. The diet of *Boa constrictor* is known to include avian prey (Greene et al. 2003. Herpetol. Rev. 34:146; and summarized in Boback et al. 2000. Herpetol. Rev. 31:244–245). Here I report the first non-passerine avian prey item, an adult black vulture (*Coragyps atratus*, Cathartidae), from an adult female *B. constrictor* (244.5 cm TL, 6.85 kg) captured on 22 May 2002, 1549 h, at the Belize City Dump, Belize, Central America (17°29'44.6"N, 88°13'25.3"W).

A *B. constrictor* was found basking with a large bolus in its stomach and appeared to have a broken mandible. After capture, it was noticed that the tail of an adult male iguana (*Iguana iguana*, 2.2 kg) was looped within the boa's mouth, distorting the gular integument. After grasping the snake by the neck, the iguana's tail protruded (~12 cm) from its mouth. It was assumed from the appearance of the bolus that the iguana extended from the pyloric end of the stomach out the mouth of the snake. The iguana was voluntarily regurgitated 2 days post-capture. The boa was collected for experiments and placed in a nylon snake bag. At 43 days post-capture, the boa produced a fecal that contained numerous feather parts and portions of a tarsometatarsus and tibiotarsus of a black vulture. Prey identification was verified by David W. Steadman at the Florida Museum of Natural History.

I thank the Belize Forestry Department, Conservation Division for the opportunity to collect the boa under permit CD/60/3/02.

Submitted by **SCOTT M. BOBACK,** Department of Biological Sciences, Auburn University, Auburn, Alabama 36849, USA; e-mail: bobacsm@auburn.edu.

BOGERTOPHIS SUBOCULARIS (Trans-Pecos Rat Snake). **PREY**. On 19 May 2003, at approximately 2300 h, we collected an adult *Bogertophis subocularis* on a roadway in the Black Gap Wildlife Management Area in Brewster Co., Texas, USA. The snake had a large lump from a recent meal, and after being placed in a cotton bag it regurgitated two nestling desert cottontail rabbits (*Sylvilagus audubonii*). One prey animal was undigested and the other was nearly completely digested except for the feet, which indicated that the animals represented different meals perhaps from different nests. The lie of the fur on the regurgitated whole rabbit suggested that it had been swallowed head-first. The snake was 415 g and the undigested rabbit was 62 g, which was 15% of the snake's mass. *Bogertophis subocularis* is known to feed on rabbits in captivity and on a variety of other mammals in nature (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque, New Mexico, 431 pp.; Reynolds and Scott 1982. *In* Scott [ed.], Herpetological Communities, pp. 99–118. USDI Fish Wildl. Serv., Wildl. Res. Report 13; Werler and Dixon. 2000. Texas Snakes: Identification, Distribution, and Natural History. University of Texas Press, Austin, 437 pp.). To our knowledge, however, this is the first report of *B. subocularis* feeding on rabbits in nature.

We thank Paul Leberg for obtaining permits and helping to collect the snake and identify the rabbits. Alan Hitch also helped identified the prey.

BOTHROPS COTIARA (Cotiara) and ***BOTHROPS FONSECAI*** (Fonseca's Pitviper). **REPRODUCTION**. Among the Brazilian continental pitvipers from southern and southeastern regions, the sister species *B. cotiara* and *B. fonsecai* (Salomão et al. 1999. Kaupia 8:127–134) have the most restricted geographical ranges. Both species inhabit isolated remnants of *Araucaria angustifolia* pine forests on highlands, which are exposed seasonally to sub-freezing temperatures (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York, 425 pp.; Müller 1971. Salamandra 7:9–30) and are under rapid habitat destruction. Data on reproduction for these species are limited, with one report on 14 embryos in *B. fonsecai* (Sazima and Manzani 1998. Herpetol. Rev. 29:102–103). Here I report on a litter of *B. fonsecai*, born on 16 March 1993, and a litter of *B. cotiara*, born on 22 March 1998. Both adult females were collected in the wild (February 1993 and January 1998, respectively) and gave birth in captivity at Instituto Butantan, São Paulo, Brazil. The former species (820 mm SVL, 105 mm TL, and 267 g after parturition) was from Fazenda Pião, Jesuânia, Minas Gerais state, Brazil (21°59'S, 45°17'W, 903 m elevation) produced seven living neonates (3 males, 2 females, 2 unsexed) (mean ± SD: SVL: 264.6 ± 14.5mm; TL: 41.7 ± 5.8mm; 12.71 ± 1.1 g), one stillborn

individual of undetermined sex, and one unfertilized ovum. Additionally, and vouchered in the Coleção Herpetológica "Alphonse Richard Hoge" at the same institution *loc cit.*, on 3 and 14 March 1961, two specimens from Queluz (22°53'S, 44°77'W, 498 m elevation) (IB 19777) and Campos do Jordã (22°73'S, 45°59'W, 1628 m elevation) (IB 19871), São Paulo state, Brazil gave birth to 9 (IB 19778–786) and 10 (IB 19872–881) living neonates, respectively. The *B. cotiara* (860 mm SVL, 90 mm TL, and 325 g after parturition) from São Joaquim, Santa Catarina state, Brazil (28°17'S, 49°55'W, 1354 m elevation) gave birth to 2 live neonates (male: 249 mm SVL 48 mm TL, and 5 g; female 196 mm SVL, 31 mm TL, and 9 g), one disfigured stillborn (unsexed: 115 mm SVL, 25 mm TL, and 10 g), and six unfertilized ova.

I thank Paulo E. Vanzolini (Museu de Zoologia da Universidade de São Paulo) and Myriam E. V. Calleffo (Lab. de Herpetologia – Instituto Butantan) for bibliographical support.

Submitted by **MARCELO RIBEIRO DUARTE**, Lab. de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, CEP 05503-900, São Paulo, SP, Brazil; e-mail: mrduarte@butantan.gov.br.

CONTIA TENUIS (Sharp-tailed Snake). **NOCTURNAL BEHAVIOR and HABITAT**. The autecology of *Contia tenuis* is poorly known. It is a small and fossorial species, ranging from central California to Vancouver Island, British Columbia (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd edition. Houghton Mifflin, Boston, Massachusetts. 533 pp.). Throughout its range, it is primarily associated with coniferous forests and oak woodlands. It is believed to be primarily active on the surface during cool, wet weather in the spring and autumn (St. John 2002. Reptiles of the Northwest. Lone Pine Publ., Renton, Washington. 272 pp.).

On 17 June 2003, at 2300 h, I observed a male *C. tenuis* (285.7 mm SVL, 7.4 g) AOR, ca. 0.10 mile S of mile-post 22 on State Route 821, Kittitas County, Washington, USA. A second specimen (12.5 mm SVL, 1.3 g,) was observed AOR at 2330 h, ca. 0.25 miles N of mile-post 19, of the same highway. Air temperature was 27.5°C. Both localities are in areas where the vegetation is dominated by rabbit brush (*Chrysothamnus* sp.), big sage (*Artemisia tridentata*), diffuse knapweed (*Centaurea diffusa*), and cheatgrass (*Bromus tectorum*).

The only report of nocturnal behavior in the literature is based on a single observation of a specimen from the southwest coast of Oregon (St. John, pers. comm.). These observations might indicate that *C. tenuis* is nocturnally active through the summer, and surface activity might not be limited to periods of rainfall or similar moist conditions.

I thank A. St. John for discussion, and D. M. Darda for commenting on this manuscript.

CROTALUS ATROX (Western Diamond-backed Rattlesnake). **ENTRAPMENT and OPPORTUNISTIC COURTSHIP**. Avian exclosure netting (e.g., Bird-X® netting, Dalen Products, Knoxville, Tennessee) is made of polypropylene and is inexpensive (mesh openings measure 18 x 26 mm). This netting is draped over trees and shrubs to exclude birds and other frugivorous animals. Herpetologists have used this material to capture aquatic snakes (Lutterschmidt and Schaefer 1996. Herpetol. Rev. 1996:131–132), suggesting that when discarded or left unattended such netting may pose a threat to wild animals (Stuart et al. 2001. Herpetol. Rev. 32:162–164). Animals trapped and immobilized in exclosure netting do not succumb immediately, but instead may remain alive for days and die from prolonged exposure to the elements. Animals trapped in this netting are at much greater risk of predation; a less recognized consequence of such entrapment is that an animal may not be able to fend off unwanted sexual advances from conspecifics. Here we report the entrapment of two *Crotalus atrox* in avian exclosure netting and a presumed opportunistic mating attempt directed at an entrapped individual. Also, we provide further evidence that exclosure netting can entrap and kill other squamates.

On 29 March 2003, during a herpetology class field trip, we explored an abandoned dump site northwest of Tucson, Arizona (USA). At 1125 h (air temperature 23.3°C, ground temperature 28.2°C, wind < 4 mph, 0% cloud cover) we observed a pair of *C. atrox* next to a bundle of black avian exclosure netting (ca. 30 x 25 x 10 cm) in full sun. Based on behavioral differences, and because we saw another pair of *C. atrox* copulating about 50 m away, we assumed the pair consisted of a male (≥ 1 m total length) and a female (< 1 m total length). The male was engaged in apparent courtship behavior, including dorsal body-looping, tongue-flicking, and chin-rubbing of the female (Gillingham 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Social Behavior, pp. 184–209. Macmillan, New York). We watched for ca. 5 min., but when disturbed by our presence, the male moved ca. 1 m into the shaded lumen of a large diameter pipe. The female was unable to retreat, apparently because she was trapped in an opening of the mesh. Closer inspection revealed that she was entangled approximately a third of the way down her body and her skin was folded and sagging, consistent with dehydration. The site of constriction and ca. 15 mm anterior and posterior of the constriction, appeared somewhat abraded and discolored, but not bloody. We believe her receptivity to the courting male may have been influenced by her immobilized state. We released her by cutting the mesh with a pocketknife taped to a snake stick and she departed into the same shade retreat as the male. The male remained atop the female in the shaded lumen of the pipe for at least two hours.

We examined the netting bundle, which itself was anchored by heavy gauge wire and other debris, and discovered remains of another dead, desiccated *C. atrox* in the mesh. Two pieces were entangled—the first (ca. 75 mm long) comprised a skull with skin and scales attached to anterior vertebrae, and the second consisted of ca. 115 mm of vertebrae with skin and scales from midbody. If it had been summer, the *C. atrox* that we released from the netting would likely have succumbed in a matter of hours without intervention.

One of us (GLB) has noted several squamate captures when avian exclosure netting was used to protect tomato plants in Avra

Valley, near Tucson, Arizona. During a two-year period of using netting in a residential garden, observed fatalities include one each of *Pituophis catenifer*, *Lampropeltis getula*, and *Phrynosoma solare;* two *Masticophis flagellum* (one individual deposited as UAZ 51802); and ca. 5 *Sceloporus magister.* Animals captured and released alive include one *Dipsosaurus dorsalis* and ca. 5 *Sceloporus magister*. Similarly, another local herpetologist (C. R. Schwalbe, pers. comm. 2003) noted that avian exclosure netting used for two years to protect a peach tree in midtown Tucson, Arizona killed several *S. magister* as well as mourning doves (*Zenaida macroura*). Thus, it seems clear that avian exclosure netting may capture a broad range of squamates, and to prevent unwanted fatalities this netting should be monitored when used.

We thank the Arizona Game and Fish Department and the students enrolled in ECOL 483 (Herpetology) at the University of Arizona, spring 2003.

Submitted by **KEVIN E. BONINE**, University of Arizona, Department of Ecology and Evolutionary Biology, P.O. Box 210088, Tucson, Arizona 85712, USA (e-mail: kebonine@u.arizona.edu), **ERIC W. SMITH**, University of Arizona, Department of Ecology and Evolutionary Biology, P.O. Box 210088, Tucson, Arizona 85712, USA (e-mail: gbradley@u.arizona.edu, smithjef@u.arizona.edu).

CROTALUS TIGRIS (Tiger Rattlesnake). **DIET**. *Crotalus tigris* is considered to be primarily a lizard eater (Lowe et al. 1986. The Venomous Reptiles of Arizona), and a *C. tigris* was observed eating a unidentified species of *Aspidoscelis* (= *Cnemidophorus*) (Ortenburger and Ortenburger 1926. Proc. Oklahoma Acad. Sci. 6:101–121). Few species of lizards, however, have been recorded in the diet of *C. tigris*. We document *Crotaphytus collaris* in the diet of *C. tigris*. On 24 July 2002 we located the radio transmitter signal of an adult female *C. collaris* (94.9 mm SVL, 174.4 mm TL, 27.3 g) with a 1.8 g radio transmitter within an adult male *C. tigris* (590 mm SVL, 173 g, including *C. collaris* and radio transmitter) in the southern Tortolita Mountains near Oro Valley, Arizona, USA (32°28.340'N, 111°00.085'W). A radiograph (Fig. 1) confirmed that the *C. tigris* had ingested the lizard and radio transmitter.

We thank Kirk Setser for his critical reading of this manuscript, and James Jarchow for providing the radiograph.

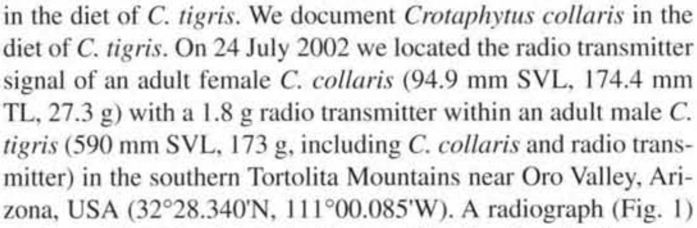

FIG. 1. Radiograph of *Crotalus tigris* showing PIT-tag (top), 1.8 g radio transmitter attached to *Crotaphytus collaris* (middle), and 5.2 g radio transmitter implanted in snake (bottom).

Submitted by **MELISSA A. AMARELLO** (e-mail: cascabel@email.arizona.edu) and **MATT GOODE,** School of Renewable Natural Resources, University of Arizona, Tucson, Arizona 85721, USA.

HYPSIGLENA TORQUATA (Night Snake). **DIET.** Few snakes have been recorded in the diet of *Hypsiglena torquata*, and records include *Crotalus viridis, Leptotyphlops dulcis, Leptotyphlops humilis,* and *Sonora* spp. (Rodríguez-Robles et al. 1999. Copeia 1999:93–100). We report an additional observation of *L. humilis* as prey of *H. torquata*. On 16 July 2002 we encountered a freshly killed adult (302 mm SVL, 61 mm TL, 13.8 g) *H. torquata* at 2205 h on a road in the foothills of the Tortolita Mountains near Oro Valley, Arizona, USA (32°27.227'N, 110°58.552'W, elevation ca. 950 m). Dissection revealed an undigested adult *L. humilis* (203 mm SVL, 11 mm TL, 1.6 g) within the *H. torquata*. Both the *H. torquata* (UTA R-52347) and the *L. humilis* (UTA R-52414) were deposited in the Collection of Vertebrates, University of Texas, Arlington, Texas.

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). **REPRODUCTION**. A *Lampropeltis triangulum elapsoides* collected on 13 March 2003 near Wilma, Liberty Co., Florida, USA, oviposited 10 eggs (total mass of 29.3 g) on 6 May 2003. The largest clutch size reported for this subspecies is seven eggs (Groves and Sachs 1973, J. Herpetol. 7:389–390), but a captive specimen laid nine eggs in each of three consecutive years (Tony Mills, pers. comm.). Immediately postpartum, the female was 60 g, 565 mm SVL, and 653 mm TL. Seven days after oviposition, the eggs had a mean length of 23.2 mm ± 1.69 SD, range = 21.5–26.4 mm, and a mean width of 14.8 mm ± 0.41 SD, range = 14.0–15.5 mm. The total mass of the adherent eggs was 32.1 g on 13 May, and 39.9 g on 19 June. All 10 eggs hatched on 26 June after 51 days of incubation at 23–30°C. Neonates had a mean SVL of 154.4 mm ± 4.25 SD, range = 148–160 mm; a mean TL of 179.6 mm ± 4.74 SD, range = 173–187 mm; and a mean mass of 2.9 g ± 0.12, range = 2.7–3.1 g. The sex ratio was 5:5.

The female laid a second clutch of eggs (N = 8) on 19 June 2003. Her mass was 80 g on 10 June three days before ecdysis, and 50 g immediately postpartum. Seven days after oviposition, the eggs had a mean length of 25.9 mm ± 1.93 SD, range = 24.6–30.4 mm; a mean width of 13.8 mm ± 0.37 SD, range = 13.5–14.6 mm; and a total mass of 25.5 g. Eggs in the second clutch were longer ($t = 3.16$, $df = 16$, $P = 0.006$) and narrower ($t = 5.69$, $df = 16$, $P < 0.0001$) than eggs in the first clutch, but the mean egg mass of the two clutches was identical. One egg hatched on 8 and 9 August, and six eggs hatched on 10 August after 52 days of incubation at 24–30°C. Neonates had a mean SVL of 136.3 mm ± 17.2 SD, range = 109–153 mm; a mean TL of 159.8 mm ± 19.5 SD, range = 129–177 mm; and a mean mass of 2.3 g ± 0.80 SD, range = 1.0–3.0 g. Neonates from the second clutch had a shorter

SVL ($t = 3.23$, df = 16, $P = 0.005$) and lower mass ($t = 2.36$, df = 16, $P = 0.03$) than those from the first clutch, primarily because of the small size of the first two hatchlings (≤ 115 mm SVL and ≤ 1.2 g). The sex ratio was 6 males:2 females.

Multiple clutching has been reported for larger subspecies of *L. triangulum* (Tryon 1984. Trans. Kansas Acad. Sci. 87:98–104; Applegate 1992. The General Care and Maintenance of Milk Snakes. Advanced Vivarium Systems, Lakeside, California. 71 pp.), but this is the first reported instance for *L. t. elapsoides*. However, a long-term captive *L. t. elapsoides* from Hernando Co., Florida, oviposited two clutches twice and three clutches once of fertile eggs from a single breeding annually (Susan Sentman, pers. comm.). Multiple clutching is undoubtedly less common in wild than in captive *L. t. elapsoides* but probably occurs occasionally in larger females, particularly in Florida where the activity period is longer than in more northerly portions of the taxon's range. Groves and Assetto (1976. Herpetol. Rev. 7:114) speculated that a clutch oviposited on 8 October by an *elapsoides* from Miami-Dade County, Florida, might indicate multiple clutching.

Submitted by **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 5300 High Bridge Road, Quincy, Florida 32351, USA; e-mail: kevin.enge@fwc.state.fl.us.

LIOPHIS TYPHLUS (Velvet Swampsnake). **COLORATION.** On 22 March 2003 an adult female *Liophis typhlus* (510 mm SVL, 105 mm TL, 61 g) was captured on the secondary forest floor at the edge of the Río Orosa near the Madre Selva Field Station (03°37'14.7"S, 72°14'47.8"W) in Amazonian Peru. The present animal matched the description in Dixon and Soini (1986.The Reptiles of the Upper Amazon Basin, Iquitos Region, Peru. Milwaukee Pub. Mus.) with the exception of coloration. Ventral scales were white with red to orange margins and numerous blotches of the same color. Dorsal scales were generally red to orange with an olive hue. The diagonal black streaks were limited to the interstitial skin and a black streak was absent between the nostril and eye.

James R. Dixon confirmed identification of the snake. A photographic record has been deposited in the University of Texas at Arlington slide collection (28997).

Submitted by **CHARLES M. WATSON,** Department of Herpetology, The Dallas Zoo, 650 South R.L.Thornton Freeway, Dallas, Texas 75203, USA (e-mail: varanid@mail.com), and **MATTHEW S. VAUGHAN,** Department of Herpetology, The Fort Worth Zoo, 1989 Colonial Parkway, Fort Worth, Texas 76110, USA (e-mail: amphibia@airmail.net).

MASTICOPHIS FLAGELLUM (Coachwhip). **DIET.** *Masticophis flagellum* feeds upon a wide variety of vertebrates including chelonians. Douglass and Winegarner (1977. J. Herpetol. 11:236–238) reported the remains of a juvenile *Gopherus polyphemus* from the feces of *M. flagellum* in Florida, and an unidentified turtle was reported in the diet of *M. flagellum* in the western United States (Ortenburger 1928. Mem. Univ. Michigan Mus. 1. 247 pp.). Other snakes, including *Crotalus adamanteus*, *Drymarchon corais*, and *Agkistrodon piscivorus conanti* are also known to prey on *G. polyphemus* (Butler and Sowell 1996. J. Herpetol. 30:455–458 and citations therein). However, we are unaware of any records of snake predation on *Gopherus agassizii*. Here we report an observation of predation by *M. flagellum* on *G. agassizii*. On 15 July 2002 at 1132 h we found an adult female *M. flagellum* (945 mm SVL, 205 g) eating a juvenile *G. agassizii* (46.6 mm midline carapace length, 17.0 g) in the southern Tortolita Mountains near Oro Valley, Arizona, USA, 958 m elevation (32°28.250'N, 111°00.528'W). Approximately half of the tortoise was ingested when we encountered the snake (Fig. 1), but the snake regurgitated the tortoise after we disturbed them. After release by the snake, the tortoise was alive but visibly damaged with a dented shell. We captured both the snake and tortoise, measured each, and placed them together in a five gallon plastic bucket. The snake made no further attempt to consume the tortoise. The tortoise died within a few hours of capture, presumably from injuries inflicted during ingestion. The tortoise measured 30.9 mm in width and 16.7 mm in height. The snake's head width (at widest point) was 19.6 mm; head length 39.6 mm, mouth length 27.1 mm. The deceased tortoise (UTA R-52413) was deposited in the Collection of Vertebrates, University of Texas, Arlington, Texas. We thank Randy Hill for the use of his photos.

FIG. 1. Adult female *Masticophis flagellum* eating a juvenile *Gopherus agassizii*.

MORELIA AMETHISTINA (Amethystine Python). **DIET**. On 20 November 1995 at about 1800 h, during fieldwork in the Crater Mountain Wildlife Management Area of Chimbu Province, Papua New Guinea, I found a large (SVL ~ 5.9 m, measured twice by four workers using a tape) adult male Amethystine Python (*Morelia amethistina*) on warm rocks in a streambed. I brought the snake back to the Crater Mountain Biological Research Station at Wara Sera (10.5 km ENE of Haia village, 6°43'S and

145°05'E) to be held until it could be weighed and photographed the following morning. The snake escaped during the night, and it regurgitated a partially digested Forest Wallaby (*Dorcopsulus macleayi*), ~ 3 kg and BL 40 cm. *Morelia amethistina* is the longest species of snake in the rainforests of New Guinea, and it is an important predator of large mammals (O'Shea 1996. A Guide to the Snakes of Papua New Guinea. Independent Group Pty Ltd., Singapore. 239 pp.). This report is the first record of *M. amethistina* eating *D. macleayi* in Papua New Guinea.

Submitted by **DAVID BICKFORD**, Department of Biology, University of Miami, P.O. Box 249118, Coral Gables, Florida 33124-0421, USA.

NOTHOPSIS RUGOSUS (Rough Coffee Snake). **REPRODUCTION.** The Rough Coffee Snake (*Nothopsis rugosus*) occurs in evergreen lowland and pre-montane forests from eastern Honduras to northwestern Ecuador; it is apparently oviparous (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). There is, to my knowledge, no information on its clutch sizes. The purpose of this note is to present information on an egg clutch from *N. rugosus*.

One female *N. rugosus* was examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA. The specimen (LACM 153777) was collected 12 June 1974, from Heredia Province, Costa Rica; it is 255 mm SVL and contained three enlarged follicles (mean length 13 mm ± 0.6 SD ± SD, range: 12–13 mm). A clutch of three eggs, presumably, would have been deposited.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California, USA; e-mail: sgoldberg@whittier.edu.

OXYRHOPUS GUIBEI (False Coral Snake). **PREDATION**. The False Coral Snake (*Oxyrhopus guibei*) is a common species in southeastern Brazil, and occurs in both forest edges and open areas. The only records of predation on *O. guibei* refer to the laughing falcon (*Herpetotheres cachinnans*) and the colubrid *Erythrolamprus aesculapii* (Sazima and Abe. 1991. Stud. Neotrop. Fauna Environ. 26:159–169). Here we report on a possible predation on *O. guibei* by the Maned-wolf (*Chrysocyon brachyurus*), the largest South American canid. On 26 April 2002, we found fresh *C. brachyurus* scat on an unpaved road crossing an area of pristine "campo sujo" (shrubby grassland; 22°12'30"S, 47°54'45"W, elev. 760 m) at Itirapina Ecological Station (IES), municipality of Brotas, São Paulo State, southeastern Brazil. The analysis of this scat revealed a fragment (125 mm) of a snake that included an intact tail. It was a young male *O. guibei* (400 mm, estimated SVL; TL was 105 mm).

Besides *O. guibei*, one species of coral snake (*Micrurus frontalis*) and two other supposed coral snake mimics (*O. rhombifer* and *Simophis rhinostoma*) occur in the area. Most predators at the IES seem to avoid snakes with coral snake color pattern (O. A. V. Marques, in prep.; F. Spina, unpubl. data), but *C. brachyurus* does not avoid them; *C. brachyurus* is known to consume venomous snakes, such as the tropical rattlesnake, *Crotalus durissus* (S. C. S. Belentani, unpubl. data) and lanceheads, *Bothrops* spp. (D. Queirolo, unpubl. data), although they are likely to be an occasional food item in most populations (less than 10% of the wolf scats have snake remains; Motta-Junior and Martins. 2002. *In* Levey et al. [eds.], Seed Dispersal and Frugivory: Ecology, Evolution and Conservation, pp. 291–303. CAB International, Wallingford, Oxfordshire, UK.); even so, *C. brachyurus* appears to be an efficient and regular snake predator in the Brazilian Cerrado.

The voucher specimen of *O. guibei* is deposited in the Museu de História Natural, Universidade Estadual de Campinas (ZUEC 2684). D. Zanchetta and the staff of Instituto Florestal allowed and facilitated our fieldwork at IES. Funded by FAPESP (00/12339-2; 00/01412-0; 99/05664-5). We thank L. Pizzatto for laboratory assistance and Gordon Schuett for suggestions. This is publication number 15 of the project "Ecology of the Cerrados of Itirapina."

TOZETTI** (e-mail: mtozetti@uol.com.br), **MARCIO MARTINS** (e-mail: jararaca@ib.usp.br), and **JOSÉ CARLOS MOTTA-JUNIOR** (e-mail: mottajr@ib.usp.br), Departamento de Ecologia, Instituto de Biociências, Universidade de São Paulo, C.P. 11461, 05508-900, São Paulo, SP, Brazil, and **RICARDO J. SAWAYA** (e-mail: sawaya@unicamp.br), Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, C.P. 6109, 13083-970, Campinas, SP, Brazil.

PITUOPHIS CATENIFER (Gopher Snake) **DIET.** *Pituophis catenifer* is a large-bodied colubrid that occupies a variety of habitats, including grasslands, oak-woodlands, open forests, as well as deserts (Stebbins 2003. A Field Guide to Western Reptiles & Amphibians, Houghton Mifflin). Its prey base is equally varied, including insects (Parker and Brown 1980. Milwaukee Publ. Mus. 7:1–104), lizards, birds, bird eggs, and mammals (Diller and Wallace 1996. Herpetologica 52:343–360, Fitch 1949. Am. Midl. Nat. 41:513–579). In a recent study, 2613 specimens of *P. catenifer* were examined from most of its distribution (Rodriguez-Robles. 2002. Biol. J. Linn. Soc. 77:165–183). Of 1066 prey items, 86 (8.6%) were birds, seven (0.7%) were nestling birds, and 127 (11.9%) were bird eggs. Here I report on the predation of multiple bird nestlings of two different taxa by *P. catenifer* from a geographic region not covered by Rodriguez-Robles (*op cit.*).

A dead-on-road male *P. catenifer* (116 cm SVL, 240.5 g) was collected on 15 June 2002, 2230 h, between mile-post 13 and 14 on State Route 821 in Kittitas Co., Washington. A noticeable bulge was present 10 cm below the head, extending well into the midbody. Upon internal examination of the snake, an egg, and five recently ingested nestlings (total mass of ingested prey was 14.1 g total) of two different avian taxa were discovered. The egg was small and crushed, and ca. 2.5–3.0 cm long. Because of its condition I was unable to make a positive species identification. The first four nestlings, positioned posteriorly in the stomach, were a species of finch or sparrow that was unidentifiable. The most common species of finch or sparrow in the area where the snake was collected is the Lazuli Bunting (*Passerina amoena*). Several nesting pairs of this species were observed in 2003 during the same

time period that the present snake was collected in 2002. The fourth and fifth birds, positioned more anteriorly in the stomach, were Western Kingbirds (*Tyrannus verticalis*). All of these prey items were preserved in 10% buffered formalin, and transferred to 70% ethanol for permanent storage at Central Washington University.

Although the number of prey items (N = 6) is interesting (only 14 specimens from the study by Rodriguez-Robles (*op. cit.*) contained six or more prey items), what is more significant is that two different avian taxa were taken in apparent rapid succession. All species of sparrow in the vicinity where the snake was found construct nests relatively low to the ground, or on the ground, and Western Kingbirds typically build nests that are elevated from the ground. It would appear likely that the present snake predated a nest near the ground and continued to forage higher, actively searching for avian prey.

I thank K. Wishert for bringing this snake to my attention and D. M. Darda, and P. W. Mattocks for commenting on this manuscript.

PITUOPHIS MELANOLEUCUS MELANOLEUCUS (Northern Pine Snake). **SEXUAL BEHAVIOR**. *Pituophis m. melanoleucus* is a large, secretive colubrid whose range in Tennessee is limited to a few disjunct populations. Seasonal timing of sexual behavior (e.g., courtship, coitus) in Tennessee populations has not been reported. The only detailed studies on the reproductive biology of *P. m. melanoleucus* have been conducted in the northern-most part of the range, in the New Jersey Pine Barrens (Burger and Zappalorti 1986. Copeia 1986:116–121; Burger and Zappalorti 1991. J. Herpetol. 25:152–160), where breeding takes place in late spring; females seek nest sites from mid-June to mid-July. Zappalorti et al. (1983. Bull. Chicago Herpetol. Soc.18:57–72) observed that this taxon mates in May. We report for the first time copulatory behavior in a pair of *P. m. melanoleucus* from Tennessee.

On 28 May 2001 at 1115 h, we observed a pair of *P. m. melanoleucus* copulating in the southwestern portion of Arnold Air Force Base in Franklin County, Tennessee, USA. The male (123 cm SVL, 1370 g) was an individual being radio-tracked. The female, which had not been observed, was immediately captured and measured (138 cm SVL, 1614 g). The snakes were ca. 1 m above the ground on piled tree trunks and branches in an open area that had been logged approximately one year earlier. The habitat was an early successional "weedy" clear-cut (formerly a loblolly pine plantation) with abundant herbaceous groundcover, no midstory or overstory, and a significant amount of post-logging woody debris. Ambient air temperature was 27°C, and no precipitation occurred in the past 24 h.

Fieldwork was funded by Arnold Air Force Base through contract to CH2M HILL.

PYTHON SEBAE (African Rock Python). **HABITAT USE and HOME RANGE.** Similar to most other species of python, the ecological and behavioral diversity of *Python sebae* is poorly understood (Pitman 1974. A Guide to the Snakes of Uganda. Codicote Weldon and Wesley, Ltd; Broadley 1983. FitzSimons' Snakes of Southern Africa. Parklands, Jonathan Ball and Ad. Donker; Shine and Fitzgerald 1996. Biol. Conserv. 76:113–122). Interpretation of existing information is obscured because a number of reports generalize and conflate data from geographically and ecologically distant regions (Stucki-Stirn 1979. Snake report 721. Herpeto-Verlag, for Cameroon forests is verbatim from FitzSimons 1962. Snakes of Southern Africa. Purnell and Sons, from South Africa). The biology of free-living individuals is restricted to a study of a Gambian population (Starin and Burghardt. 1990. The Snake, 24:50–62) and one from Nigeria (Luiselli and Akani 1999. Herpetozoa 11:99–107; Luiselli et al. 2001. African J. Ecol. 39:116–118). Here I present radio-telemetric data on habitat use and home range size and characteristics of a single adult female *P. sebae* in the rainforest of southwestern Cameroon.

Locations of *P. sebae* were confined to a mosaic of secondary forest and farms near Bayenti village, Southwest Province, Cameroon. A description of the area is published (Lawson 1993. Herpetol. Nat. Hist. 1:27–90). The present female was collected on 12 Nov 1996, from a snare separating a small subsistence farm from secondary forest. At the time of capture she was ~ 2.4 m SVL, and 3.7 kg. On 15 Nov, she was implanted (Raphael et al. 1996. Wildlife Disease Association Annual Meeting Proceedings, Alaska. p. 82) with an Advanced Telemetry Systems (ATS, Isanti, Minnesota, USA) radio-transmitter with 3 h duty cycle and 3 mo life-span, and released at point of capture 18 Nov. The radio-transmitter was replaced 28 Feb 1997 with an ATS temperature sensitive transmitter and released 11 Mar at the second point of capture. On average, she was located ~ 48 h for one year (201 locations 19 Nov 1996–18 Nov 1997) using a Custom Electronics CE-12 or Telonics TR-2 receiver and hand-held H-antenna. The snake was directly observed on only one occasion as it sheltered approximately 5 m above the ground in the crotch of a tree in a farm. At every other location, she was concealed, either below ground, under and/or inside a log or debris, or high in a tree. Sampling intensity varied monthly from 100% of days in Dec to 20% of days in May, and seasonally from 66% of dry season days (Nov–Mar), to 47% of rainy season days (Apr–Oct). Positions in the field were surveyed and related to a single point geo-referenced with a hand-held global positioning system. Minimum convex polygon and harmonic surface area home range estimates (Table 1) were derived using the Computer Aided Mapping and Resource Inventory System (CAMRIS version 3.46, Ecological Consulting, Inc., 1997). The present female greatly expanded its range into the forest during the dry season; however, the majority of both dry and rainy season movements and locations were confined to a core area of approximately 24000 m^2.

General and microhabitat utilization shifted between seasons

with the snake occupying underground retreats in more open, disturbed areas during the rainy season. In the dry season, she was located 53% of the time (100 samples) in forest, 19% in farm, 22% in a stream, and 6% in heavily disturbed areas (either under a timber bridge along an active logging road or in an abandoned rock quarry). In the dry season, 38% were arboreal, 44% underground, and 18% aquatic. In the rainy season, the snake was located 28% of the time (100 samples) in forest, 41% in farm, 8% in a stream, and 23% in heavily disturbed areas. Of these locations, 31% were arboreal, 57% underground, and 13% aquatic. Although the relative importance of particular habitat types may vary among geographic regions and individual snakes, the utilization of a mosaic of habitats within an individual range as observed here is supported by the observations of Starin and Burghardt (*op. cit.*) as well as other accounts. Broadley (*op. cit.*) reports large specimens of *P. sebae* lying along low, overhanging branches to drop on prey, but does not indicate that they exploit higher forest strata. Starin and Burghardt (*op. cit.*) state that arboreal behavior was not observed in the population they studied in Gambia. Pope (1973. The Giant Snakes. Alfred A. Knopf) emphasized that *P. sebae* lacks strong arboreal tendencies. Although these reports might be partially attributable to structural differences among habitats, the present individual was an excellent climber, and she spent considerable time in canopy habitats. When occupying arboreal retreats, she was typically far above the ground (> 5 m) and not visible. Lack of visibility in arboreal retreats might explain the absence of arboreal observations by Starin and Burghardt (*op. cit.*). Large adult size might preclude the use of some arboreal retreats, but this microhabitat is clearly significant for rainforest animals < 3 m in length.

In this study, the female was within 10 m of a stream or river 81% of times located. Of the 39 locations away from water, 17 occurred in the dry season and 22 in the rainy season. Only 15 of 49 individual retreat locations were >10 m from a stream or river, reflecting this species' reported affinity for water in general accounts from other areas (Murphy and Henderson 1997. Tales of Giant Snakes: A Historical Natural History of Anacondas and Pythons. Krieger Publ. Co., Malabar, Florida). My study female seemed to use streams and a river as travel corridors, occasionally being located in a retreat several hundred meters up or downstream from the previous day's location.

I recorded the present female at 49 different retreats (32 in the dry season, mean 6.4/mo; 39 in the rainy season, mean 5.6/mo) with 37 locations/retreats being used only once, 9 twice, 1 three times, 1 four times, and 1 on 7 different occasions in 6 different months. Of the 12 sites used multiple times, 5 were tree tops adjacent to or overhanging a river; 3 were under logs or other cover immersed at the edge of the river; 2 were under logs and debris in a swampy overgrown pocket in a farm, one was under a log in a small coffee farm, and one was under/in a timber bridge in the middle of the road. She spent >10 d at a single retreat on at least five occasions. The two longest stays were in excess of 20 d following transmitter replacement, but stays of 12, 13, and 15 d occurred during the dry season in rock quarry, in stream, and in coffee farm, respectively. Multiple days in one location might belie more complex movement patterns from secure retreats. On one occasion, at 0848 h, she was tracked to the same site that was occupied the previous day. At 1400 h, a farmer reported that a python (the present female) was in a snare adjacent to his farm ca. 140 m up a small stream from the snake's location earlier in the day. However, given that this snake was located over 200 times and never observed active, it is unlikely that diurnal movement from secure retreats was commonplace. Limited forays from retreats might be an important, but as yet unappreciated, aspect of the species' behavior.

Starin and Burghardt (*op. cit.*) estimated a population size of 20–25 adult *P. sebae* in a study area similar in size (0.335 km^2) to the total minimum convex polygon home range estimate of the present female. Despite that she was trapped on two occasions in one year, no other pythons were found or collected within this animal's home range, and there was only a single reliable report of a large python several kilometers away in similar habitat. Although additional animals could have gone undetected, it is extremely unlikely that more than a few adults had overlapping ranges with the study animal. My observations indicate that this species is not common in the rainforest zone. The extensive use of wire snare traps in the farm/forest mosaic and incidental killing undoubtedly decimate already low forest populations near human settlement.

The present female was weighed in the early dry season at the time of capture (3.7 kg), late in the dry season when recaptured for transmitter replacement (3.4 kg), and late in the rainy season when it was again found in a trap (4.85 kg). These few measurements indicate a loss of mass during the dry season, with considerable gain during rainy season. Body temperatures varied from 24.1°C (Jul) to 34.1°C (May) and did not closely follow ambient temperatures. Available ambient temperatures ranged from 21.5°C to 37.5°C.

***TANTILLA RETICULATA* (NCN). ARBOREAL ACTIVITY.** Neotropical species of the genus *Tantilla* are fossorial insectivores reported to live under moss and leaf litter (Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two

Continents, Between Two Seas. The University of Chicago Press, Chicago. 934 pp.). A single individual of *Tantilla reticulata,* collected from under moss on a tree limb at a height of 6.1 m, is the only documented case of any arboreal activity for this species (Wilson and Meyer 1971. Herpetologica 27:11–40).

In the course of several years of work in the canopy of Costa Rican rainforests, four individual of *T. reticulata* were observed crawling on tree branches at heights of over 27 m. None of these individuals, unfortunately, was vouchered. On 8 March 2003, during a visit to Rara Avis Rainforest Reserve, Heredia Province, Costa Rica (10°18.16'N, 84°02.62'W; 650 m elev.), an adult *T. reticulata* was observed falling from the thatched roof of a building from a height of ~ 5 m. In addition, on 12 March, about 1400 h another *T. reticulata* was observed actively moving about on an epiphyte-covered branch of an emergent canopy tree (*Vantanea barbouri*) at a height of 30.7 m above the ground. Both snakes were collected, photographed (YPM slide collection 1025–26), and released *in situ*. Gregory Watkins-Colwell verified identification of the present snakes.

These observations indicate that *T. reticulata* is more arboreal than previously assumed. The crowns of epiphyte-laden trees in the Rara Avis area provide a microhabitat with a humus layer and moss cover that is often more extensive than that of the local forest floor. It is not clear, however, how these small snakes detect the presence of a suitable habitat far overhead or how they succeed in reaching the canopy, crossing a vertical distance of 30 meters on smooth tree bark.

TRIMORPHODON BISCUTATUS (Western Lyresnake). **PREDATION**. On 7 May 2003, 1250 h, we tracked a male *T. biscutatus*, 810 mm SVL and 153 g, implanted with a 5.2 g radio transmitter in the southern Tortolita Mountains near Oro Valley, Arizona, USA (32°28.201'N, 110°59.015'W). We located the transmitter signal from within 1 m of a *Bubo virginianus* (Great Horned Owl) nest site, which was actively defended by an adult pair of *B. virginianus*. Assuming the snake was dead, we left the site to avoid disturbing the owls further. On 14 May 2003, the owls were not present at the nest, and we found an owl pellet containing the snake's transmitter (Fig. 1) just below the nest. Great Horned Owls are generalist predators, preying on a variety of vertebrates including snakes (Houston et al. 1998. Great Horned Owl. Birds of North America. 372:1–28). We know of no previous records of avian predation on *T. biscutatus*.

FIG. 1. A pellet from *Bubo virginianus* containing a 5.2 g radio-transmitter from *Trimorphodon biscutatus*.

Drift fences used with pitfall and/or funnel traps are a standard field technique used to sample amphibian and reptile communities (Campbell and Christman 1982; Corn 1994). Drift-fence sampling is effective in collecting large numbers of animals in a relatively short period of time (Gibbons and Semlitsch 1981; Rodda et al. 2001).

A variety of materials have been used for drift fences, but aluminum flashing is the best choice for long-term studies because of its durability (Gibbons and Semlitsch 1981). Aluminum flashing is expensive and often is not feasible for short-term inventory studies that do not have a large budget. Polyurethane has been used for drift fences to study amphibian reproductive biology by encircling breeding ponds (Douglas 1979).

Enge (1997) proposed the use of silt fencing as an alternative. Silt fencing is a woven polypropylene material that is about one-third the cost of aluminum flashing and is particularly desirable when sampling hydric environments. Silt fencing can also be used in terrestrial habitats. Zug et al. (2001) report the use of silt fencing for monitoring amphibian and reptile populations at a tropical site in Myanmar and one of us (JHM) has used silt fencing for short-term sampling (2–3 months) of herpetofaunal communities in the Edwards Plateau of Texas.

In the tropics, where "common species are rare and rare species are common" (Forsyth and Miyata 1984), drift-fence sampling might be an effective technique to sample amphibian and reptile species, yet little data are available (but see Brown et al. 1996; Zug et al. 2001). In the United States aluminum flashing and silt fencing are both readily available, but elsewhere, particularly in the tropics, this may not be the case. Furthermore, the cost of importing aluminum flashing or silt fencing via air carrier might be exceedingly high because of the weight of the material. Another problem with drift fencing in wet tropical forest is the high rate of treefalls (Brokaw 1996). Treefalls can destroy aluminum or silt-based drift fencing and require considerable effort to repair (pers. obs.). Therefore, for drift fence sampling to be convenient and feasible in a tropical forest, the material must be available, affordable, and the drift fence should be repairable in a modest amount of time. As an alternative to aluminum flashing and silt fencing, we herein describe the use of polystyrene to construct drift fences

used in a baseline amphibian and reptile inventory of Parque Nacional Carara (PNC) (09°46'27.0"N, 84°36'20.0"W), Puntarenas Province, Costa Rica.

Polystyrene, a thermoplastic, is more rigid than polyurethane. We purchased 0.76-mm thick polystyrene in 180 x 120 cm sheets from a plastic dealer in San Jose, Costa Rica (Serigráficos Suretka S.A. c/o Plasticom M&F). The cost of this material was ca. US \$53/trap (one trap = 19.44 m^2 of fence or \$2.73/m^2 of polystyrene) which is less expensive than US \$71/trap (\$3.65/m^2) for aluminum flashing. We cut these sheets into 40 x 180 cm sections that were rolled into bundles for delivery to the sampling site. Nine sections were laid end to end and slightly overlapped, thereby creating a drift-fence arm ca. 15 m in length. Lacquer thinner solvent (33.7% acetone, 2.8% methyl isobutyl ketone, 1.9% glycol ether, 37.3% heptane, 8.6% isopropyl alcohol, 3.9% methanol, and 11.9% toluene) was applied to each section with a paint brush. There is a health risk associated with inhaling vapors of lacquer thinner and care should be taken to avoid excessive exposure to vapors. These overlapping sections were pressed together for approximately five seconds to fuse the sections, thereby creating a continuous fence. Because the sections are fused and not glued, the fence can withstand a myriad of weather conditions without coming apart.

Drift fences were installed in a "Y" formation. Each fence arm was set upright and held in place using 40 cm wooden stakes at ca. 2 m intervals. Leaves were then placed at the bottom of the fence to seal gaps and prevent animals from crawling under the polystyrene. Each fence arm was set at an approximately 120° angle. At the end of each arm and at the junction of the three arms, a 19-liter plastic bucket was sunk flush with the substrate. A notch was cut into the lip of each bucket to hold the fence in place. In the middle of both sides of each arm (ca. 7.5 m) a 45-cm funnel trap was placed flush with the polystyrene fence, for a total of six funnel traps/array. Funnel traps were made by rolling a 45 x 60 cm section of 3-mm aluminum screen into a cylinder. Next, two cones were fashioned from two 30 x 60 cm sections of aluminum screen. These cones were inserted on each end of the cylinder and attached with baling wire to form the completed funnel trap.

During 154 trap nights from May 1999 to April 2000, six polystyrene arrays were used to sample amphibians and reptiles (one array open/night = one trap night). A total of 41 frogs, 76 lizards, and eight snakes were captured, representing 28 species of amphibians and reptiles. The most common frog species was *Dendrobates auratus* with 20 captures. *Ameiva leptophrys* was the most common lizard species with 28 captures. *Mabuya unimarginata, Micrurus alleni, Rhadinaea decorata,* and *Urotheca decipiens* were recorded in the park only from drift fence captures.

In the case of treefalls, polystyrene drift fences offer advantages over other materials. A treefall on aluminum flashing or silt fencing is difficult to repair and can leave the array with permanent damage (pers. obs.). Polystyrene fences can be fixed quickly and easily. During this study, several treefall events occurred. Repair was accomplished by moving the tree or branch, cutting out the broken fence sections and replacing them with new sections using methods described above. After tree removal, the fences were repaired in ca. 15 minutes. Repair is further facilitated by the fact that materials can be rolled into light bundles for easy transportation.

Acknowledgments.—We kindly thank Miguel Regueyra Edelman for suggesting the use of polystyrene as a potential drift fence material. This study was authorized under Ministero del Ambiente y Energía Resolución No. 237-98-OFAU and Resolución No. 019-2000-OFAU. The East Texas Herpetological Society and the Explorers Club (Youth Activity Grant) provided funding to JHM. Also, thanks to James and Mary Dixon, and Thad Williams for helping to install drift fences and constructing funnel traps. The Parque Nacional Carara staff provided facilities and logistical support during the study. Janalee Caldwell edited and thereby greatly improved the quality of the manuscript.

For arboreal lizards, field studies often are impractical because of poor visibility in the canopy, whereas laboratory studies lack realism. The use of large, outdoor enclosures that allow for movement and behavioral observation would provide the researcher an opportunity to observe behavior in a semi-natural setting while maintaining the ability to manipulate and control desired experimental variables. However, the literature is void of any suggestions on how to construct large, outdoor enclosures for studying arboreal lizards. We describe a technique for constructing large outdoor enclosures for arboreal lizards and outline a methodology for monitoring diurnal movement patterns within these enclosures using focal observations.

Enclosure design and construction.—We constructed six, large outdoor enclosures for use in a behavioral and physiological study of the panther chameleon, *Furcifer pardalis*. In this study, it was necessary to observe and record behavior while simultaneously manipulating variables related to physiological parameters. This required the use of large enclosures that allowed for experimental manipulation and ease of behavioral observation. Each circular enclosure measured ca. 2.2 m in height and 2 m in diameter. We are presenting the specific dimensions of the enclosures used in our studies, however potential modifications of the dimensions to suit other studies will be discussed below. The enclosures were constructed using 1.27 x 2.54 cm mesh welded wire. Welded wire was purchased in 30-m rolls and measured 1.2 m in width. We surveyed the study site to determine the areas most suitable for enclosure construction. Typically, we constructed enclosures near trees 2 m or less in height with dense foliage. Once a central tree was designated, all other trees were cleared from the area within a 2-m radius.

Small, moveable markers were used to outline a uniform circle of ca. 2 m diameter around the tree. A trench was then dug to a uniform depth of ca. 10–15 cm along the circle. The width of the trench was ca. 7.5–12.5 cm to accommodate any expansion or sliding of the wire. We measured the circumference of the trench and cut a piece of welded wire commensurate in size (adding 30–60 cm for overlap). We placed the wire in the trench, with the ends overlapping, and temporarily secured each end to form an enclosed circle. Four, small metal posts were placed along the outside of the enclosure, and the wire was secured to the posts to prevent collapse. Once secured vertically to the posts, we permanently

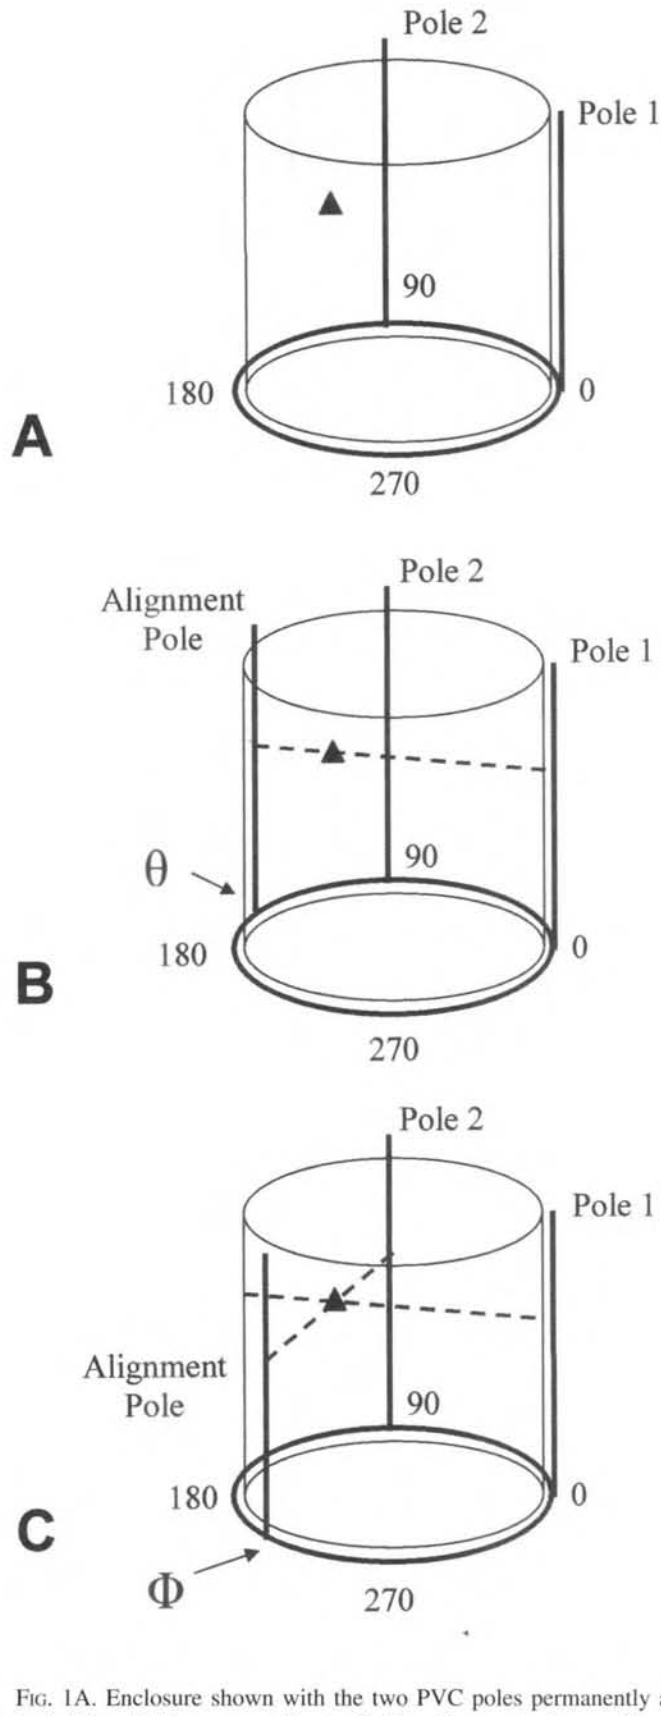

FIG. 1A. Enclosure shown with the two PVC poles permanently attached at 0 and 90 degree coordinates. B. The alignment pole was aligned in the same plane as the lizard (solid triangle) and the pole at 0 degrees (θ). C. Next, the alignment pole was aligned in the same plane as the lizard and the pole at 90 degrees (Φ). Additionally, the height of the lizard was recorded (H_L), providing a quantitative three-dimensional position. See text for details.

secured the overlapping ends of the wire using J-clamps. We then placed aluminum flashing with a width of 60 cm along the inside of the enclosure, then filled the inner portion of the trench with soil to press the flashing flush with the wire. The aluminum flashing prevents arboreal lizards from climbing onto the welded wire (with the exception of lizards with adhesive toe pads), preventing them from using the wire rather than the enclosed habitat. Once the flashing was flush with the wire mesh on the inside, we filled the outer portion of the trench with soil. This 1.2-m high wire structure serves as the foundation for the rest of the enclosure.

We then cut another section of wire of the same circumference as the first section of wire to serve as the second layer, adding an additional 80–90 cm in height to the enclosure. The second layer was secured to the first layer permanently using J-clamps, with ca. 30–40 cm overlap, yielding a total height of ca. 2.0–2.1 m.

To allow access to the inside of the enclosure, we cut a 1 x 1 m square out of the side of the enclosure, and placed a piece of wire mesh slightly larger than the opening over the entrance, securing the left side using J-clamps. This procedure allows door opening and closing with minimal bending of the wire. We securely fastened the door (the unattached end) to the enclosure using taught springs with hooks on each end, providing quick opening and closing of the door.

We constructed the roof of the enclosure using two sections of wire mesh cut ca. 60 cm larger in diameter than the enclosure. These two pieces were attached using J-clamps to form a square piece of mesh that was larger than the diameter of the enclosure by 60 cm on all four sides. The square piece (roof) was securely attached to the enclosure by weaving it to the side of the enclosure with steel wire. The top piece was then cut to a circular shape, and we made eight additional cuts perpendicular to the cylinder to allow segments to be bent downward and lay flush with the sides of the enclosure.

Construction of one enclosure requires approximately two days work, and costs ca. US $90–100. This design provides a sturdy, yet affordable and long-lasting enclosure. After four years, there have been no signs of degradation of enclosures.

Monitoring diurnal movement patterns.—Movement patterns of arboreal lizards can be monitored using these enclosures. To precisely monitor movement patterns, one needs three coordinates to find an exact location in three-dimensional space. We marked coordinates around the circumference of the enclosure, from zero to 359 degrees. At zero degrees, we secured to the enclosure a 2.54 cm wide PVC pole approximately the same height as the enclosure. At 90 degrees, we attached another pole to the enclosure (Fig. 1A). We utilized a third pole of similar size, in combination with the other two, to determine the three-dimensional coordinates of a lizard at any given time. However, the third pole (hereafter referred to as the alignment pole) was not secured to the enclosure, but instead was movable. We marked the alignment pole with height markers starting from zero at ground level. We placed the alignment pole along the outside of the enclosure while visually aligning the alignment pole, the lizard, and the pole located at zero degrees within the same linear plane (Fig. 1B). We then recorded the first coordinate by noting the degree at which the alignment pole was located (angle θ). To obtain the second coordinate, we visually aligned the alignment pole, the lizard, and fixed pole two (at 90 degrees) in the same linear plane and recorded the degree at which the alignment pole was located (angle Φ, Fig. 1C). Using the height markers on the alignment pole, we next recorded the height at which the lizard was found (H_L), giving a precise, quantitative three-dimensional location of the lizard (Fig. 1C). Utilizing this methodology, we monitored lizard movement patterns throughout the enclosure for the duration of a 12-h diurnal period. Data collection required human presence near the enclosure for brief periods, but there were no observable impacts on lizard behavior. However, caution must be exercised to minimize the duration of coordinate data collection as longer periods of data collection may adversely affect lizard behavior.

This three-dimensional tracking method can be used to replicate animal movements, or it can also be visually interpreted in a three-dimensional scatterplot. Converting actual coordinate data (θ, Φ, H_L) into an x-y-z coordinate scatterplot requires the use of a series of relatively simple equations:

$$x = 1 + \alpha / \alpha - \beta \qquad (1)$$

$$y = -\alpha(\beta - 1) / \beta - \alpha \qquad (2)$$

$$z = \gamma (H_L / H_T) \qquad (3)$$

where:

$\alpha = \sin\theta / (\cos\theta - 1)$

$\beta = (\sin\Phi - 1) / \cos\Phi$

γ = enclosure height / enclosure radius

H_L = height of lizard

H_T = height of the enclosure

Coordinate data recorded from the enclosures (θ, Φ, and H_L) can be converted to x-y-z coordinates using many types of spreadsheet software packages. Once the data are converted to a three-dimensional scatterplot, data points can be viewed as a cloud of microhabitat locations (using software packages such as SigmaPlot or SPSS), or the distance traveled by the organism can be calculated providing the radius and height of both the actual and virtual enclosures are known. In the x-y-z scatterplot, the radius of the enclosure is 1 unit. In our study, the height of the enclosure was approximately two times the radius, thus the height of our enclosure in an x-y-z scatterplot is 2 units. However, the ratio of height:radius (γ) should be adjusted for studies that deviate from our dimensions.

This design establishes a protocol that might be beneficial in many behavioral studies. This technique can be used to determine movement directions, movement patterns, movement distances, and microhabitat use in relation to environmental variables in a variety of organisms. Although these enclosures were constructed for use in studies of arboreal chameleons, they could be used in other studies where behavior might be difficult to record in the field. This design is flexible enough to allow the researcher to modify enclosure size, depending on the size and spatial requirements of the animal. This design might be extended to other taxa including arboreal *Sceloporus* species, *Abronia* species, other chameleon species, or even avian or small arboreal mammals. A shorter, larger diameter enclosure could also be employed in studies of terrestrial, non-fossorial lizards. Not only does this enclosure design provide plasticity in construction parameters, but it

also provides an ideal way to observe and quantitatively record movement patterns and microhabitat locations without disturbing animal behavior.

Little is known about the activity patterns and habitat use of fossorial anurans. Radiotelemetry provides a solution to tracking such individuals over longer periods of time (Richards et al. 1994). However, transmitters need to be implanted for anurans that spend a substantial proportion of their time buried underground. In anurans, the healing of cuts after transmitter implantation, is made extremely difficult especially in small species that inflate their lungs in response to disturbance or as a means to enlarge underground burrows.

In this study we describe a method of immobilizing frogs that prevents sutures from rupturing and thus shortens the healing process after implantation of transmitters. This method was used in a study of the population biology of the pig-nosed frog *Hemisus marmoratus*. Our study was conducted in the Comoé National Park, Ivory Coast, West Africa at the beginning of the rainy season in 1997. Previous work in West Africa has shown that female pig-nosed frogs provide parental care in terrestrial breeding chambers (Rödel et al. 1995) and release tadpoles by either opening flooded chambers or leading tadpoles to open water over a slide (Kaminsky et al. 1999). Our objective in transplanting transmitters in females was to obtain information on migration patterns and habitat use during the breeding season.

Materials and Methods. —To determine movement patterns of pig-nosed frogs we implanted radiotransmitters (1.15 ± 0.04 g) into the body cavity of five females. We used a PLL synthesized tracking receiver (TRX-1000S, Wildlife Materials Inc.) and senders with individual frequencies (Holohil Systems Ltd.) that had a maximal range of 50 m, a life-span of two to four weeks, and were equipped with magnetic reed switches to activate or deactivate the sender.

Females were captured at a drift fence as part of a long-term study of the population biology of *H. marmoratus*. We picked only females whose mass was at least 10 times that of the sender (12.7 ± 1.08 g, range 11.8–14.5 g). Males were too light to be included in the study (range 2.5–5.6 g). Females were anesthetized by placing them in a 0.001 % solution of MS-222 Sandoz (Sigma). After 30 min females were turned on their backs and a small incision made through the ventral skin and abdominal wall. The activated sender was then placed in the abdominal cavity and the peritoneum and epidermis sown together with linen thread.

To prevent the fresh suture from rupturing when females inflated their lungs, a common occurrence in many anuran species, individuals were placed in customized plastic restrainers (Fig. 1). Restrainers were molded from an alginate (Alginoplast, Bayer Dental) imprint of a large female museum specimen. The alginate was diluted to a watery solution to lengthen processing time. After the alginate had hardened and the preserved specimen had been removed, we poured a fast-binding dental plaster (Dento-Stone Klassik, Dentona) into the mold. The ventral side of the female mold was then covered with translucent foil (Omnidur 2 mm, Omnident) to form the bottom of the restrainer. The foil was heated with a Bunsen burner to make it workable. The dorsal side of the mold was fitted with light hardening plastic (Individo Lux, Voco) to form the top of the restrainer. Caudal and cranial holes of 3–5 mm were left open to allow water to pass through the restrainer.

Females who had been implanted with radiotransmitters were placed into the restrainer and both halves held together with rubber bands. To prolong battery life, a magnet was placed on the restrainer to activate the switch and interrupt the current in the transmitter. To reduce the duration of anesthesia, water was repeatedly poured through the restrainer until we could clearly see females breathing through the translucent bottom. Restrainers were then packed into a wet towel to prevent females from desiccating and the healing process observed through the opaque half of the restrainer. After three days females were removed from the restrainers and placed into plastic terraria (23 x 15 x 24 cm) with a wet sponge for several days. After new epidermis had formed, the

FIG. 1. Restrainer used to immobilize females after surgical implantation of a radiotransmitter.

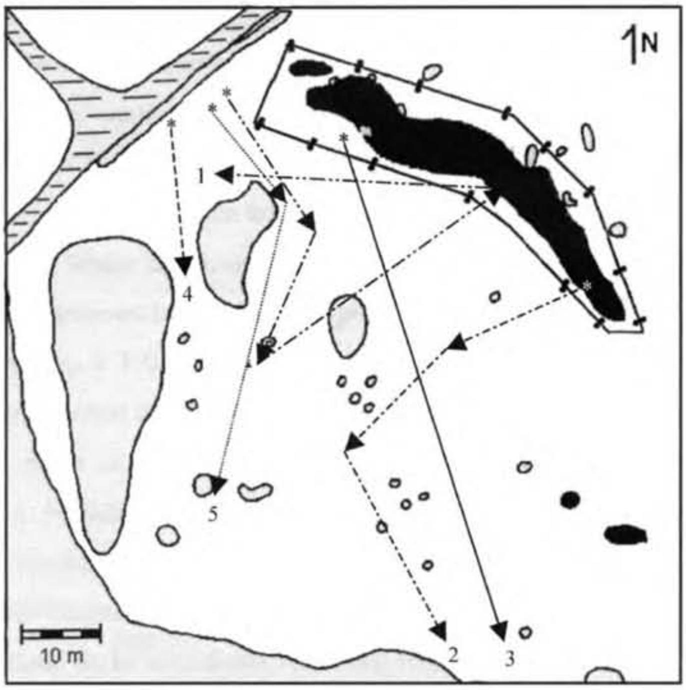

FIG. 2. Patterns of movement of five *Hemisus marmoratus* females implanted with transmitters. Black surfaces indicate ephemeral ponds, white areas grass savanna, gray areas bush savanna and the hatched area is a dirt road. The black lines with circles show the location of a drift fence with pit traps. Stars indicate where females (1–5) were found and released after transmitter implantation. Arrows show the direction of movement and numbers indicate the location at which females were last found. Last sites of females 2 and 3 were outside the area of the map.

suture fell off together with the voided skin. Because females spent most of their time underneath the sponge it was possible to place a magnet underneath the terraria to continue interrupting the circuit in the transmitter. Females were released with the next rains at the study site after wounds had completely healed. Their position was determined telemetrically at regular intervals two to three times a day.

Results and Discussion.—We followed five females and determined their activity pattern over a time period between 8 and 32 days. No adverse effects of surgery were seen in females recovered in the field. Fig. 2 shows the movement patterns of females. FEMALE 1: We followed Female 1 for 32 days. She remained for eight days at the release site, migrated 40 m south on a night after it rained and spent 11 days submerged under a clump of grass. Two days later Female 1 was found in amplexus at the fence; we placed her over the fence and two hours later she was still in amplexus trying to leave the fenced area. We again lifted her over the fence; she traveled west for 40 m where she was located underground, presumably attending eggs in her nest. Female 1 remained at this site for the following 11 days until a downpour flooded the area and the signal was lost. Most probably the female opened the nest cavity that night, released her tadpoles and left the study area. FEMALE 2: Female 2 burrowed 5 cm into the ground after being released inside the fenced area. She did not move for 15 days at which time battery power was low and she was excavated. This female was again implanted with a transmitter and released at the same site; upon release she migrated over 185 m south on three nights when it rained. Six days after being released her signal was lost. FEMALE 3: Female 3 moved 150 m into the bush savanna during one night and spent nine days buried under a grass clump 5 cm beneath the surface until reduced battery power led us to excavate her and remove the transmitter. FEMALE 4: Female 4 spent four days buried underground at the release site until it rained; she then moved 25 m in a southerly direction, burrowed into the substrate again and remained there for the next eight days. Despite an intensive search, no signal was detected the next day. FEMALE 5: Female 5 also spent four days buried underground. During the next rain she migrated 60 m southeast, then to the southwest. After five days underground, we lost contact with Female 5.

The loss of signals can be attributed to females leaving the study area, to predation, or to transmitter failure (although we think transmitter failure unlikely). All females that were fitted with transmitters were active above ground after rains. Dry periods between rains were spent underground where they were seemingly inactive. This activity pattern is consistent with earlier studies that suggest the pig-nosed frog spends most of its time below ground and emerges mainly for reproduction and possibly to feed (Passmore and Carruthers 1979; Rödel 2000; Stewart 1967; Wager 1986).

The telemetry data did not reveal use of distinct home ranges. Instead individual females seemed to roam widely throughout the area. Additional pig-nosed frogs need to be followed to determine whether they use distinct home ranges or not. It seems likely that we followed females during their excursions to and from breeding sites and that their home ranges lie elsewhere (see Spieler and Linsenmair 1998).

None of the females recovered showed any infections, inflammations, or other negative effects of the implants. Implanted transmitters have the great advantage of not hampering frogs searching for retreat sites or in amplexus and are an absolute necessity in tracking fossorial species such as *H. marmoratus*. The restrainer described in this study prevents sutures from rupturing due to lung inflation in response to disturbance and thus considerably shortens the healing process. It is recommended for all small anurans in which transmitters are implanted.

Acknowledgments.—We thank the government of the Ivory Coast for granting the necessary research permits. For assistance in the field we thank Alexandra Dill and Annette Schmidt. We also acknowledge the technical expertise provided by Christian Menrad and Müller's dental laboratory in Wolfsburg. The experiments comply with current laws and ethical standards in Germany and the Ivory Coast. This study was supported by grants from the Volkswagenstiftung (AZI/64 102) and the Deutsche Forschungsgemeinschaft (SFB 251/B3).

Recent reports of amphibian declines have sparked increased efforts to inventory and monitor amphibian populations worldwide (Keisecker et al. 2001; Pechmann and Wilbur 1994). Standard techniques for the quantitative inventory and monitoring of amphibian populations include systematic observations, automated recording of calling anurans, drift fences with pitfall traps, and aquatic funnel trapping of amphibian larvae (Heyer et al. 1994). Terrestrial drift fence arrays with pitfall traps are an effective way to sample general species richness of amphibians and can be especially effective at detecting rare or cryptic species (Corn 1994; Gibbons and Semlitsch 1982). Drift fences intercept the movements of animals and guide them into traps, generally increasing capture rates (Corn 1994). Aquatic drift fences, or net leads, have been effectively used to increase trap capture rates for fish (Hubert 1983) and turtles (Vogt 1980); however, they have seldom been used to sample aquatic amphibian species and life stages (but see Beuch and Egeland 2002; Enge 1997a).

One preferred method for sampling aquatic amphibians and amphibian larvae is funnel trapping of aquatic environments (Heyer et al. 1994; Olson et al. 1997). A variety of funnel traps have been used, including cylindrical wire or plastic minnow traps, collapsible rectangular traps, and plastic soda bottles with the top inverted (Adams et al. 1997; Beuch and Egeland 2002; Willson and Dorcas 2003). Beuch and Egeland (2002) tested the efficiency of several different types of aquatic funnel traps for capturing amphibian larvae in seasonal forested wetlands in Minnesota. They applied the drift fence principle to aquatic funnel trapping by staking a 3.0-m section of minnow seine between two cylindrical minnow traps. They concluded that the seine did not increase trapping efficiency.

We compared the effectiveness of aquatic drift fences to traditional funnel trapping for capturing amphibians within a large ephemeral wetland in the western Piedmont of North Carolina. We used a paired-sample design, with five pairs of trap arrays, to account for spatial variation in amphibian abundance within the wetland. Each pair consisted of one experimental and one control array, set 1 m apart in a straight line (Fig. 1). The relative position (right or left) of the experimental and control arrays was determined randomly and locations for the five pairs of trap arrays within the wetland were chosen based on comparability of water depth (approximately 0.5 m) and uniformity of habitat.

Each experimental array consisted of four collapsible rectangular mesh minnow traps [model RN10; Memphis Net and Twine Co. Inc., Memphis, Tennessee; US $10.99] placed at each end and along the middle of a 3.0-m long section of silt fencing (Enge 1997) supported by three wooden stakes (Fig. 1). To ensure that trapped animals had access to air we placed an air-filled 0.6-L soda bottle inside each trap to serve as a float and tied traps loosely to 1-m bamboo garden stakes, allowing the trap to slide up and down with fluctuations in water level. Each control array consisted of four traps, positioned identically to the first array, but without silt fencing (Fig. 1). To examine the efficiency of this technique, we recorded the time required to set up and monitor both experimental and control arrays.

We checked traps every other day between 17 March and 3 April 2002 and identified to species, counted, and released all amphibians captured. MANOVA (SAS 2000; alpha = 0.05) was used to assess the effects of fencing on amphibian captures and to make univariate comparisons for individual species, life stages, and number of species captured between experimental and control traps.

Over the 18-day trapping period we captured a total of 998 amphibians representing 8 species (Fig. 2). Traps with drift fencing

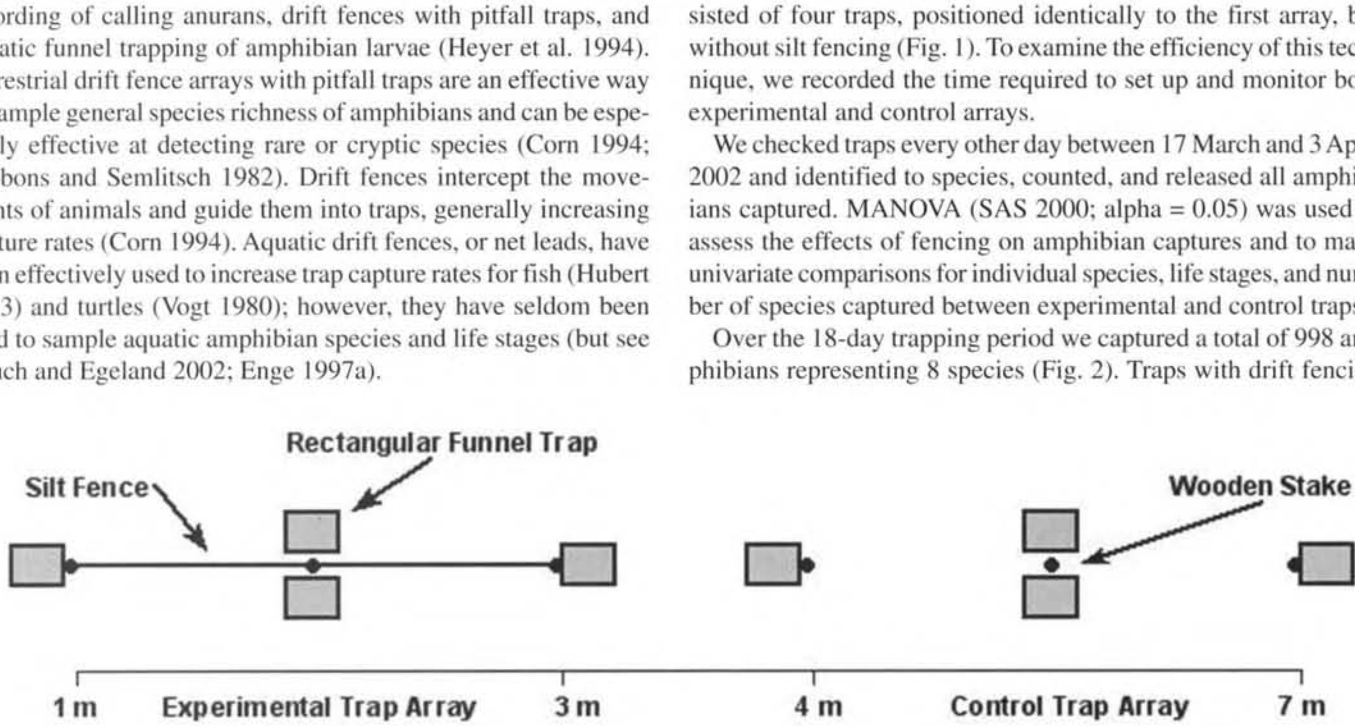

Fig. 1. Design for control and experimental trap arrays. Each array consisted of a set of four rectangular funnel traps. One array of funnel traps was placed along a section of silt fencing and one was not. Five pairs of trap arrays were set within the wetland.

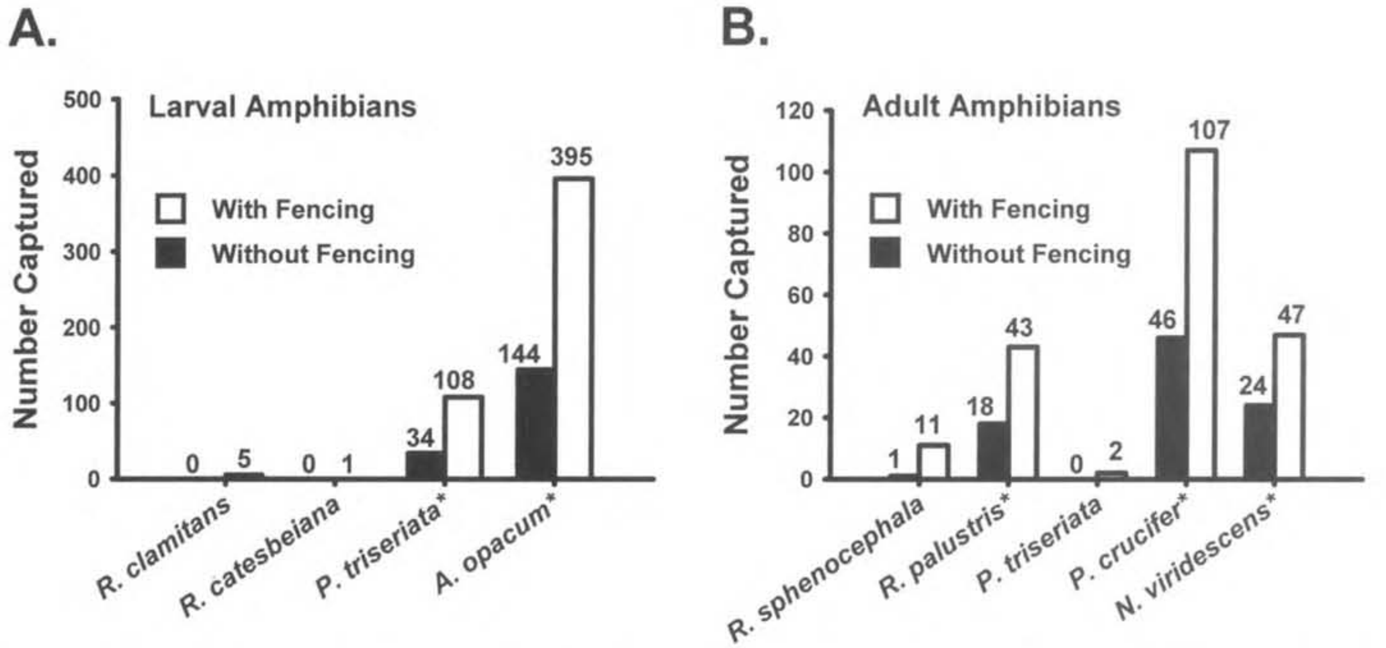

FIG. 2. Total captures of A) amphibian larvae and B) adult amphibians by species between trap arrays with and without drift fencing in a large seasonal wetland within the western Piedmont of North Carolina. Asterisks (*) denote significant differences in number of individuals captured between traps with and without fencing when compared using MANOVA.

captured over twice as many individual amphibians as did control traps (Fig. 2; MANOVA, $P < 0.0001$). Univariate comparisons revealed that traps with fencing captured significantly greater numbers of larval *Ambystoma opacum* ($F = 43.93$, $df = 1$, $p < 0.001$), and *Pseudacris triseriata* ($F = 12.15$, $df = 1$, $p = 0.001$), and adult *Rana palustris* ($F = 6.96$, $df = 1$, $p = 0.012$), *P. crucifer* ($F = 15.60$, $df = 1$, $p = 0.003$), and *Notophthalmus viridescens* ($F = 8.81$, $df = 1$, $p = 0.005$) than did traps without fencing. Additionally, traps with fencing captured significantly more species or life stages per trap than did unfenced traps ($F = 19.62$, $df = 1$, $p = < 0.001$). Small sample sizes prevented detection of statistically significant differences in other species and life stages, though for all species, traps along the fences captured more individuals than traps without fencing (Fig. 2).

The construction of aquatic drift fences added approximately $1.50 US to the cost and approximately 4 min to the installation time of each trap when compared to funnel traps without fencing. However, both the amount of time and money invested per amphibian captured was substantially lower when drift fences were used in conjunction with the traps (Fig. 3).

Buech and Egeland (2002) found that net leads had no effects on capture rates of amphibians in Minnesota temporary wetlands. They speculated this result might be due to the sedentary nature of the larval amphibians they captured (*R. sylvatica*, *A. laterale*, and *P. crucifer*). In our study, placing funnel traps along lengths of silt fencing greatly improved capture rates of both large, highly mobile amphibians (e.g., adult ranid frogs, *P. crucifer*, and *N. viridescens*) and small amphibian larvae (e.g., *A. opacum* and *P. triseriata*). We suspect that we recorded substantially higher success rates with aquatic drift fences than did Buech and Egeland (2002) because we used rectangular funnel traps, which can be placed flush along the side of the fencing, rather than cylindrical funnel traps. Cylindrical funnel traps cannot not lie flush against the fencing material and thus allow amphibians to easily swim over or under the trap openings.

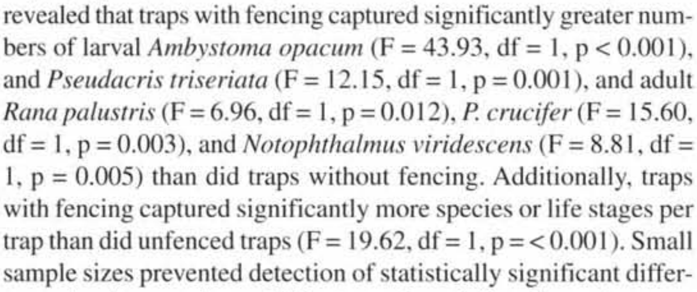

FIG. 3. Comparisons of A) cost and B) time invested per amphibian captured between traps with and without drift fencing.

In conclusion, creating aquatic drift fences by placing rectangular funnel traps along sections of silt fencing significantly improved amphibian capture rates, and thus offers a valuable and efficient complement to traditional sampling techniques for surveying and monitoring amphibian populations. Although further research is necessary, we suspect that aquatic drift fences would also prove superior to traditional funnel trapping for capturing aquatic reptiles (e.g., watersnakes) and detecting rare aquatic reptile and amphibian species.

Acknowledgments.—We thank Patricia Peroni for help in designing this study and Peroni and Machelle Wilson for assistance with statistics. We also thank Tony Mills for initial advice and ideas, Phil Gandy and Allan White for use of their property, Sarah Budischak, Ana Gabela, Pierson Hill, Sarah Hooper, Yurii Kornilev, Megan O'Neill, Laurent Ropars, and Susan Willson for assistance checking traps, and J. Whitfield Gibbons, Peri Mason, and Kimberly Andrews for providing useful comments on the manuscript. PVC Pipe Diameter Influences the Species and Sizes of Treefrogs Captured in a Florida Coastal Oak Scrub Community

TAD M. BARTAREAU

Florida Department of Environmental Protection
Rookery Bay National Estuarine Research Reserve
300 Tower Road, Naples, Florida 34113-8059, USA
e-mail: Tad.Bartareau@dep.state.fl.us

Artificial refugia constructed of polyvinyl chloride (PVC) pipes has shown to be effective for capturing treefrogs, yet capture success has varied among species, size classes, pipe designs, and placement (Boughton et al. 2000; Moulton et al. 1996). Differential capture success in studies using multiple PVC pipe designs indicates that at least some species or size classes of treefrogs are selective in their use of artificial refugia (Boughton et al. 2000; Moulton et al. 1996). Therefore it is reasonable to expect that variation in the PVC pipe design may change the detection probability of different species and sizes of treefrogs under artificial refugia, bias count data, and population estimates, unless this effect is known. Consequently, a validation experiment was undertaken to critically assess the influence of PVC pipe diameter on the species and sizes of treefrogs captured under artificial refugia in a Florida coastal oak scrub community.

The study was carried out at Rookery Bay National Estuarine Research Reserve (RBNERR) in Collier County, Florida, USA. RBNERR encompasses ca. 50 ha of coastal oak scrub that occurs in a mosaic with pine flatwoods on well-drained and lightly colored sands. The most extensive tract of oak scrub located adjacent to Shell Island Road was selected for study on the basis that it offered an area large enough for investigation (> 5 ha) with uniform soils, vegetation and topography, while allowing easy access. The study site does not have a flowing water source, and the hydroperiod of small depression ponds is dependent upon localized rainfall and rising groundwater. The low (< 4 m) canopy is dominated by a sparse to dense layer of *Quercus chapmani, Q. geminata, Q. myrtifolia,* and *Ceratiola ericoides*, with *Pinus elliottii* appearing occasionally as an emergent. The lower shrub layers are more complete with *Serenoa repens*, *Lyonia lucida*, *Ximenia americana* and *Asimina reticulata*. Ground cover is sparse yet diverse, frequently with bare siliceous sand, or with lichen, spikemoss, and occasional tufts of grass and herbs. Preliminary surveys at the study site captured *Hyla cinerea, H. squirella,* and *Osteopilus septentrionalis* taking shelter in the cavities of *Q. chapmani* and axils of *S. repens* (pers obs.).

Three identical PVC pipe arrays were set out widely spaced (> 100 m) at random. Each array was comprised of 1-m long sections of four different diameter pipes (13, 25, 38, and 51 mm) inserted upright 10 cm into the ground directly along side each other. This pipe design and placement was chosen because of the naturally low canopy height combined with the preferences of *H. cinerea* and *H. squirella* for long (60 cm) PVC pipes driven into the ground or hung vertically in trees (Boughton et al. 2000). Each pipe was set up 20 July 2001, and data were collected during 12 widely spaced (15–35 d) capture sessions from 21 July 2001 to 5 May

Table 1. Number of *Hyla cinerea*, *H. squirella* and *Osteopilus septentrionalis* captured and recaptured among different PVC pipe sizes.

Species	Pipe Diameter (mm)					
	13		25		38	
	Capture	Recapture	Capture	Recapture	Capture	Recapture
H. cinerea	8	2	19	7	—	—
H. squirella	17	4	42	22	11	—
O. septentrionalis	—	—	5	1	12	10

2002. During capture sessions, each pipe was checked between 0900 and 1500 h. Treefrogs were removed from a pipe and placed in a 19-liter bucket with lid, measured, marked (Hero 1989), and then released directly back into the same pipe. Snout–urostyle length (SUL) was measured with a ruler fitted with a right-angle stop at one end, and age classes were specified as juvenile when SUL was < 37 mm for *H. cinerea*, < 23 mm for *H. squirella* (Wright and Wright 1949), and < 28 mm for *O. septentrionalis* (Meskaka 2001).

Capture and recapture data among different pipe sizes were analyzed as described in Boughton et al. (2000). Repeated measures Analysis of Variance (ANOVA) were used to identify differences between number of captures among pipes of each array and size. The Least Significant Difference (LSD) test was then used to identify differences between the levels of each significant variable. Count data was transformed ($y' = \div\{y + 0.5\}$) due to zero values and in order to normalize variances. ANOVA for unbalanced designs was used to identify differences in the SUL of treefrogs using each pipe size and the duration of recapture of individuals. Spearman's correlation coefficient (r_s) was used to detect relationships in the coexistence of treefrogs among each array. Mean values are followed by ± 1 SE.

Over a period of 289 days, there were 114 captures of 68 individuals of three species, with 46 recaptures (Table 1). *Hyla squirella* were captured most frequently (61%) followed by *H. cinerea* (24%) and *Osteopilus septentrionalis* (15%). These treefrogs are nocturnal feeders, foraging mainly on insect prey of the shrub and herb strata, remaining inactive and taking shelter during the daylight hours except when the humidity is high (Goin 1958; Goin and Goin 1957; Haber 1926; Kilby 1945; Meshaka 2001). We currently have a limited understanding of why the treefrogs are using the PVC pipes, but the attraction might simply be because they provide suitable diurnal shelter from adverse environmental conditions. Similar to the cavities of trees and axils of bromeliads and palmettos (Lee 1969; Neill 1951), PVC pipes placed upright in the ground retain moisture and provide a place of shelter from the sun, wind, and predators. The preference for moist refugia is indicated by the data that PVC pipes hung vertically in trees capped on the bottom with water inside were used more frequently by *H. cinerea* and *H. squirella* than those of the same diameter that were either capped on top or uncapped (Boughton et al. 2000). Stewart and Pough (1983) found that introducing bamboo refugia increased the density of a treefrog species on those plots, perhaps by increasing their protection from predators. For example, Neill (1951) captured *Elaphe obsoleta rossalleni* in a bromeliad with two *H. cinerea* in its stomach. During this study, *Coluber contrictor priapus* were observed feeding on adult *H. squirella* and *O. septentrionalis*, but this and other snakes would have difficulty climbing the PVC pipes and the small diameter prevents entry by other potential predators such as birds and mammals.

Treefrog captures were made only within the 13, 25, and 38 mm diameter pipes (Table 1). Most of the captures of both *H. cinerea* (70%) and *H. squirella* (60%) were in the 25 mm diameter pipes. The majority of *O. septentrionalis* captures (91%) were in the 38 mm diameter pipes. The number of captures of all three species varied significantly with pipe size ($P < 0.0006$), but only *O. septentrionalis* showed significant ($P = 0.012$) array-to-array differences (Table 2). *Hyla cinerea* and *H. squirella* were captured significantly ($P < 0.05$) more in 25 mm pipes than in 13 or 38 mm pipes. Similarly, where PVC pipe refugia were driven into the ground, 98% and 2% of pooled *H. cinerea* and *H. squirella* captures were in 20 mm and 50 mm pipes, respectively (Moulton et al. 1996). These studies present consistent evidence that both *H. cinerea* and *H. squirella* discriminate between artificial refugia sizes, and the majority of individuals will take shelter within 20–25 mm pipes.

Some of the variation in captures of each species can be attributed to the significant positive relationship between pipe diameter and treefrog size ($N = 114$, $r_s = 0.65$, $P < 10^{-4}$). The SUL of individuals varied with pipe size (Table 3). All species except *O. septentrionalis* showed significant ($P < 0.05$) pipe-size to pipe-size differences. Native treefrogs captured in the pipes were of juvenile and adult age, but all *O. septentrionalis* were adults (Table 3). Neill (1951) indicated that the majority of *H. cinerea* and *H. squirella* found in bromeliads were juveniles. In the same way, variation in the PVC pipe diameter was an important determinant of the sizes or age classes of *H. cinerea* and *H. squirella* that took shelter within it. The average size of treefrogs increased with increasing pipe diameter, and only juveniles and small adults used the 13 mm pipes. Juveniles and adults of most sizes and age classes used the 25 mm diameter pipes. Only adult *H. squirella* and *O.*

Table 2. ANOVA table for repeated measures analyses, comparing number of *Hyla cinerea*, *H. squirella*, and *Osteopilus septentrionalis* captured among different arrays and PVC pipe sizes.

Source	df	*H. cinerea*		*H. squirella*		*O. septentrionalis*	
		F	P	F	P	F	P
Array	2, 94	0.61	0.549	1.11	0.331	4.59	0.012
Pipe Size	2, 94	18.6	< 0.0001	18.4	< 0.0001	8.3	0.0006

septentrionalis used the 38 mm pipes. Likewise, Boughton et al. (2000) discovered that with 38 mm PVC pipes hung vertically in trees, only a small proportion of all *H. cinerea* (1.6–3.2%) and *H. squirella* (0.9–2.4%) captures were juveniles. Thus, the use of pipes < 13 mm or > 25 mm diameter will significantly change the detection probability of different sizes of *H. cinerea* and *H. squirella* under artificial refugia, bias count data, and population estimates.

Several researchers indicated that *H. cinerea, H. squirella* (Boughton et al. 2000; Goin and Goin 1953; Goin 1958; Moulton et al. 1996), and *O. septentrionalis* (Meshaka 2001) might return day after day to the same resting site. Overall, 33%, 37%, and 65% of all *H. cinerea, H. squirella,* and *O. septentrionalis* captures were recaptures. Marked individuals of each species were recaptured over 15–155 days during the study period, which suggest the maintenance of a partially confined activity range. Of all recaptures, 83% were within the same initial size pipe and the remainder moved from 13 or 38 mm to 25 mm diameter pipes. Excluding individuals captured only once, *O. septentrionalis* occupied a pipe for the longest number of consecutive days (60 ± 33, range = 15–155, N = 4) followed by *H. cinerea* (37 ± 7, range = 15–64, N = 7) and *Hyla squirella* (33 ± 4, range = 15–92, N = 22) but differences were not significant ($F_{2,30}$= 1.69, P = 0.210). The failure of individuals to return to the same pipe over longer periods of time indicates that they might have occupied a much larger range and simply chose a different resting place, fell victim to some predator while out foraging, or some negative factor associated with being captured.

TABLE 3. Mean (± SE, range) snout–urostyle length and age classes of *Hyla cinerea*, *H. squirella*, and *Osteopilus septentrionalis* captured among different PVC pipe sizes. ANOVA differences at the P = 0.05 level are indicated by different letters.

Species	Pipe Diameter (mm)		
	13	25	38
H. cinerea	22 ± 0.6a, 19–24	32 ± 1.1b, 29–42	—
Adult	—	2	—
Juvenile	8	17	—
H. squirella	26 ± 0.7a, 22–33	34 ± 0.6b, 24–41	37 ± 1.5b, 30–41
Adult	14	42	11
Juvenile	3	—	—
O. septentrionalis	—	41 ± 1.8a, 37–48	45 ± 1.3a, 41–55
Adult	—	5	12
Juvenile	—	—	—

Groups of treefrogs in PVC pipes are common (Boughton et al. 2000; Moulton et al. 1996), but little is known about how different species and age classes interact. Some of the variation in *H. squirella* captures might be attributed to the significant negative correlation with the coexistence of *O. septentrionalis* (N = 36, r_s = –0.54, P < 10^{-4}). There were no significant correlations between the coexistence of *H. cinerea* and either *H. squirella* (N = 36, r_s = –0.06, P = 0.732) or *O. septentrionalis* (N = 36, r_s = 0.06, P = 0.722). Meshaka (2001) found negative relationships between *H. cinerea, H. squirella*, and *O. septentrionalis* and suggested that predation was responsible for the unstable coexistence of these species across a wide variety of coastal habitats. The degree to which *O. septentrionalis* might reduce populations of native treefrogs is unknown.

Although little is known about use of artificial versus natural refugia, enough information might be gleaned from validation experiments to know that the occurrence of different species and size classes of treefrogs under PVC cover will vary to some degree with pipe diameter and the presence of *O. septentrionalis*. However, by setting out a standardized number of 25 mm pipes, it is possible to inventory and monitor most sizes and ages classes of *H. cinerea, H. squirella*, and *O. septentrionalis* with a consistent sampling technique. The 13 mm and 38 mm pipes can be used to examine more specifically juvenile or adult populations, respectively. PVC pipes placed along transects between breeding and non-breeding habitats cover the greatest area and potentially provide more information on movement, home range size, and habitat requirements than do random sites. Mark-recapture techniques might be used to examine populations of these treefrogs year-round, across different breeding and non-breeding habitats.

Acknowledgments.—Support was provided by Rookery Bay National Estuarine Research Reserve, and collection and handling procedures were conducted under the auspices of permit number WV01455 of the Florida Fish and Wildlife Conservation Commission. Thanks to Jennifer Bartareau, Renee Wilson, and anonymous reviewers for comments on the manuscript.

Auburn, Alabama 36849, USA
e-mail (RDB): birkhrd@auburn.edu

We describe here a device that allows a large number of venomous snakes to be transported and manipulated while minimizing risk to the snakes and investigators. We developed a need for such a device in the course of our investigations of the ecology of the cottonmouth (*Agkistrodon piscivorous*). Our device expands on the use of clear tubes for capture or restraint of venomous snakes (Fowler 1995; Murphy 1971).

Our device, the "cottonmouth condo," consists of 10 lengths of polyethylene tubing (McMaster-Carr part number 2044T49) attached to a pair of central spacers. We use tubes that are 60 cm long and 4.2 cm diam, a size that accommodates all but the largest individuals in our study population. The central spacers can be made of wood or closed cell foam (which allows the unit to float) the edges of which have been notched with semi-circular holes drilled into the margin (Fig. 1). The notches are spaced 5 cm apart on center to provide clearance between tubes. The tubes are glued onto the central spacers and then bound together with duct tape. The tubes are open at both ends allowing snakes to be inserted or removed from either end. The ends of the tubes are capped with replacement end caps designed for fluorescent light bulb safety shields (McMaster-Carr part number 1626K11). These end caps fit tightly and have an oval hole in the center to provide air for the animals inside and to drain water in the event that the unit is briefly submerged. Friction fit of the caps can be increased by wrapping thin strips of duct tape around the end of the tubes. For transport of animals that are small enough to fit through holes in the endcaps, vinyl shipping tube caps (McMaster-Carr part number 2044T69) with a small hole punched in the end are placed over the standard end caps. Alternately, vinyl coated fiberglass window screen can be glued inside the caps. The tubes are numbered to assist in keeping track of captures and the device has a shoulder strap for easy transport in the field.

For use in the field, caps are removed from one end of all tubes. Once a snake is encountered, the condo is laid horizontally on a nearby log, mud flat, or vegetation mat. The snake is then captured with Pilstrom-style tongs and the head maneuvered into an open tube. In general, we have found that snakes readily enter the tube as the jaws of the tongs are slowly relaxed. When more than half of the snake's body is within the tube, the tail can be grasped and examined safely for scale clips or other identifying marks. Once the snake is fully in a tube, an end cap is used to close the tube. Because the transport tubes often are of a larger diameter than the snakes being captured, care must be taken to prevent the snake from doubling back before the end cap is placed or while checking for scale clips.

In the laboratory, snakes can be removed for further examination by removing the end cap nearest the head and inserting a separate polyethylene tube of smaller diameter, usually just slightly larger than the maximum diameter of the snake (see Fowler 1995; Murphy 1971). Snakes that are reluctant to move can be prodded gently from the opposite end of the tube through the oval opening, allowing the end cap to remain in place. Once laboratory procedures are completed, return of the snake to the condo can be accomplished in one of two ways. First, the tail (untubed) end of the snake can be placed in the condo tube and the snake's head can be prodded gently with a soft plunger until the snake crawls backward into the condo tube. When the snake's head is four to five inches from the opening of the transport tube the restraining tube can be removed and an end cap of the condo reattached. Alternately, the head end of the handling tube can be placed into the condo and the snake allowed to crawl forward into the condo tube.

When releasing snakes, the end cap nearest the snake's head is removed and the condo held at the opposite end at a slight downward angle allowing the snake to crawl out. The snake may be gently prodded from the opposite end, through the opening in the end cap, to initiate movement.

Over three years, we have used this system to transport cotton-

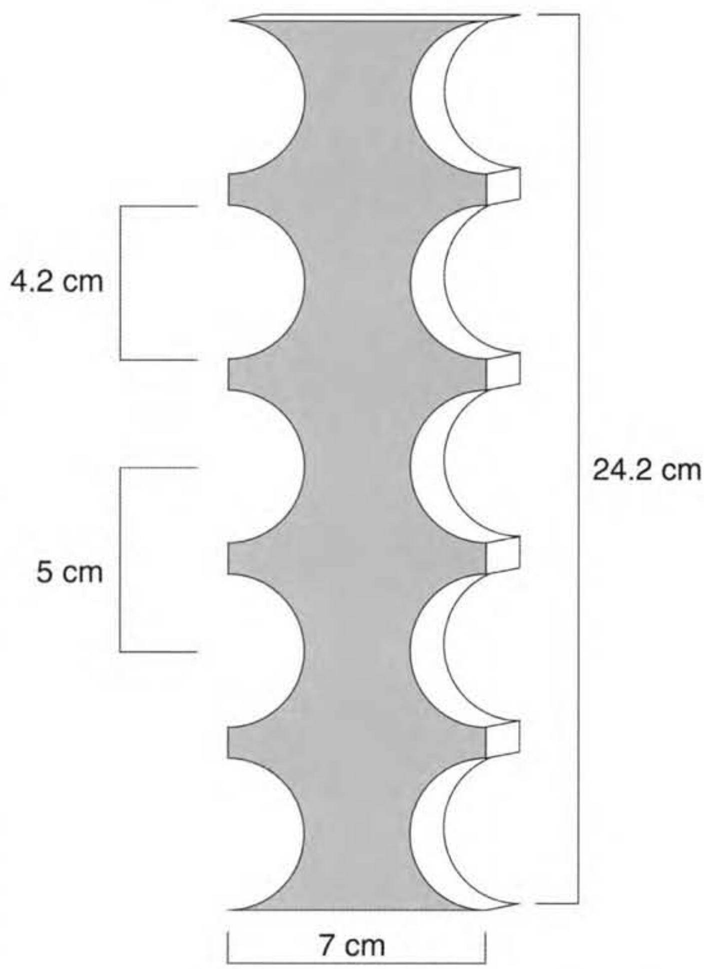

FIG. 1. Template for the construction of the central spacers for the tube unit. Dimensions are indicated with brackets. The wood or foam used should be at least 1.8 cm thick.

mouths on a regular basis (N = 321) without injury to the animals or investigators. Snakes have been safely retained within the tubes for up to 24 h with no obvious ill effects. Snakes handled in this method have been recaptured numerous times over the course of three years (maximum of 12 recaptures for an individual). By using the tube-to-tube transfer method, snakes are only gripped with tongs once throughout their capture, transport, and release.

To limit potential stress from visual stimuli (the researcher or snakes in adjacent tubes) the tubes can be abraded with coarse steel wool or fine sandpaper to make them opaque on the sides and/or ends. However, we point out that the safety of this device is derived from the transparency of the polyethelyne tubes and thus care should be taken not to compromise this feature. As with any closed container, care should be taken to avoid overheating. We also suggest regularly checking tubes and caps for damage. Damaged tubes are easily replaced by removing the duct tape, removing and replacing the tube, and reapplying duct tape. Cleaning and sterilizing can be accomplished by using an appropriate sized bottlebrush taped to a dowel to scrub the insides.

Our device costs ca. US $20.65 to build. A future improvement would be to incorporate screw caps, however we have been unable to locate any readily available source. Many diameters and lengths of tube can be purchased for use with other species or life stages of different lengths and girths. Tubing and caps can be ordered inexpensively from industrial supply houses such as McMaster-Carr Supply Company (http://www.mcmaster.com, 6 January 2003).

Although this technique might not be appropriate for every research situation, we have found the use of this system has improved both the safety and efficiency when working with cottonmouths. Finally, let it be said that no system is foolproof and there is no substitute for common sense.

Acknowledgments.—We thank C. Guyer for his encouragement and reviews, T. E. Haines with the Tuskegee National Forest for permission to conduct research requiring the development of this device (Special Use Permit TUS 700705), and two anonymous reviewers.

Biologists often need simple, reliable, safe, and inexpensive ways to identify individual study animals. For field and laboratory research on snakes, identification techniques include scale clipping, external tags, paint marks, tattoos or brands, and natural markings (e.g., for reviews see Ferner 1979; Lang 1992; Wright and Minott 1999). Recent studies have used passive integrated transponder (PIT) tags and radio transmitters to identify individual snakes in the field. However, these devices require equipment that can be prohibitively expensive for some projects; in such cases, alternative marking techniques are necessary. Permanent natural markings that are clearly visible, such as color patterns, can be valuable for non-invasive field identification of small to moderate samples (e.g., Carlström and Edelstam 1946; Francini et al. 1990; Hardy and Greene 1999).

In laboratory and field studies on Western Diamondback Rattlesnakes (*Crotalus atrox*), we have used sketches, photocopies, and photographs of the black and white banding pattern on the tail to identify individual snakes. The tail banding pattern varies substantially among individuals (Fig. 1). In 240 *Crotalus atrox* studied over several years on the grounds of the Arizona-Sonora Desert Museum, no two snakes had the same tail banding pattern. Each of these snakes was also marked by painting the rattle, clipping the ventral scales, or implanting PIT tags, which aided in verifying the identification based on tail pattern. Furthermore, tail banding patterns did not change with growth in 21 neonate snakes that were raised in the laboratory for one year. Natural markings are also fixed throughout the life of each individual in other species such as *Natrix natrix* (Carlström and Edelstam 1946). Similar tail patterns in different individuals might occasionally lead to false-positive identifications, but the frequency is lower than 0.4% (1 in 261 individuals).

To keep track of large numbers of individuals, photographs or sketches of the tails can be categorized by the banding patterns. For example, we have used a hierarchical system of organizing individual patterns based on (a) the number of solid black bands, (b) the number of offset black bands, (c) the number of broken black bands on the right side, (d) the presence and completeness of a dorsal stripe connecting the black bands, (e) the consistency in width of the black bands along the tail, and (f) the number of spots or blotches in the white bands. Other ordered systems (e.g., Francini et al. 1990) might work equally well if the criteria are clear and systematically applied.

Pronounced black and white tail bands occur in several rattle-

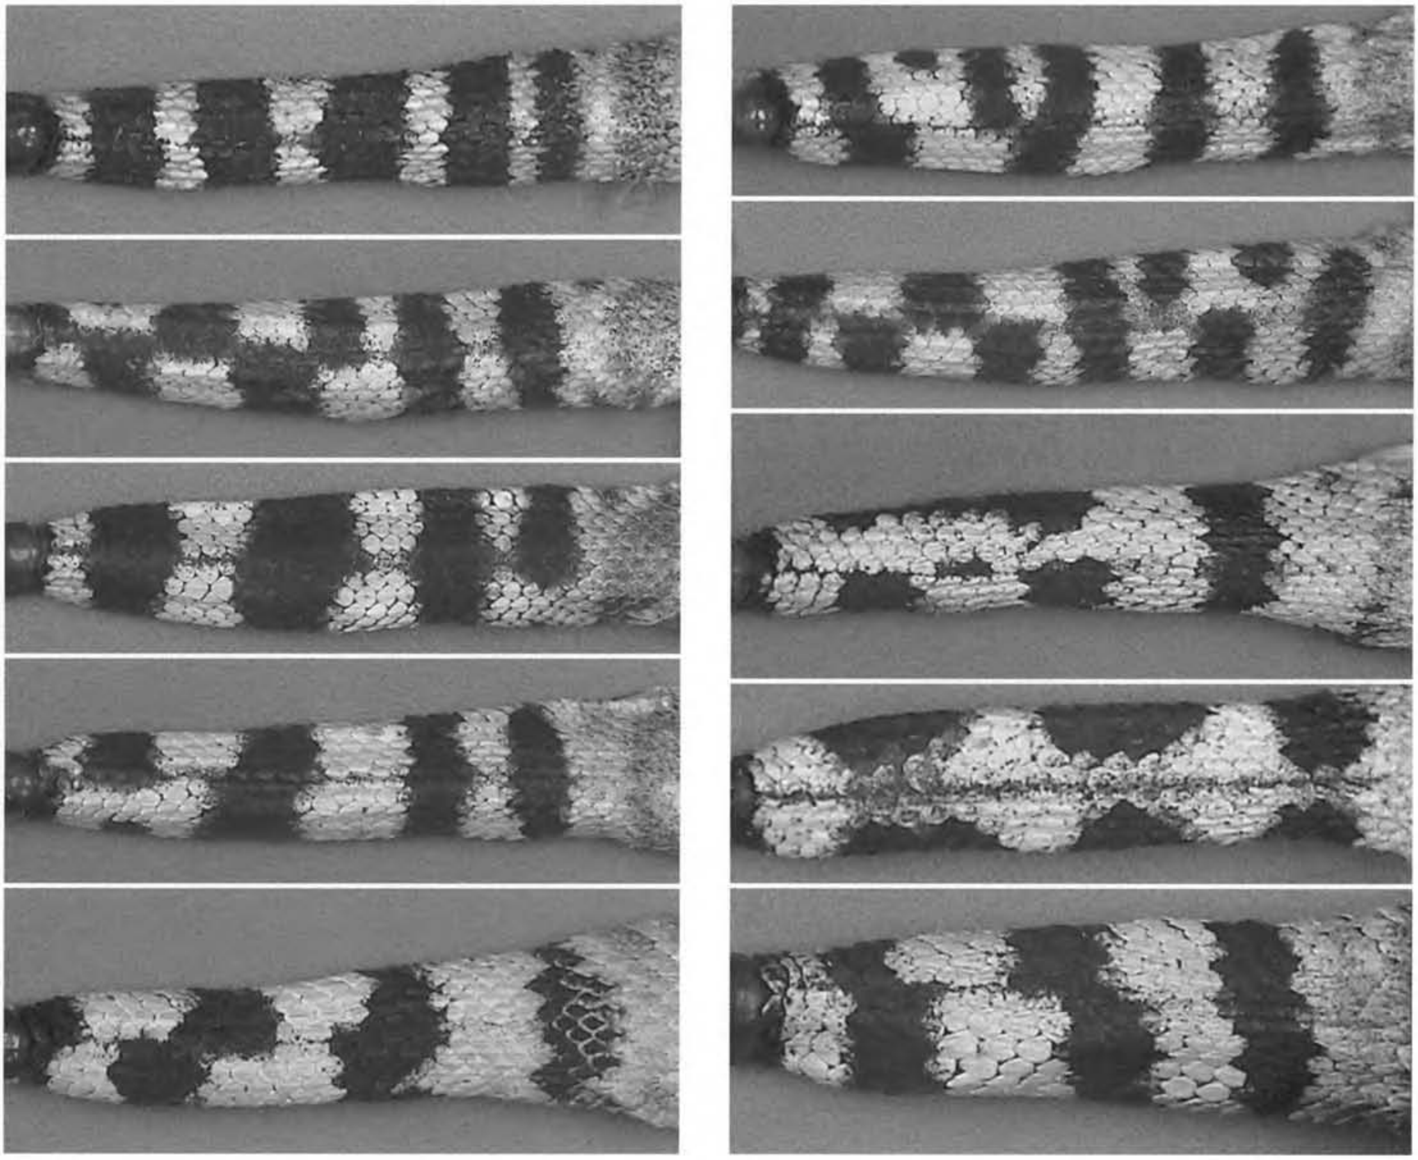

FIG. 1. Photographs of the tails of 10 Western Diamondback Rattlesnakes (*Crotalus atrox*) representing a small sample of the diversity of tail banding patterns. Photographs not to same scale.

snakes, including *Crotalus atrox*, *C. catalinensis*, *C. ruber*, *C. scutulatus*, and *C. tortugensis* (Klauber 1972). Less pronounced banding patterns occur in some populations or individuals of *C. adamanteus*, *C. cerastes*, *C. lepidus*, *C. mitchellii*, and *C. viridis*, among other species (Klauber 1972; Werler and Dixon 2000). These banding patterns might be useful for identifying individual snakes in the field without capturing them, at least whenever the animal's posture keeps the tail visible. Even when the tail is hidden, minimal disturbance might induce the snake to reveal it.

Major advantages of using natural patterns to identify individual snakes are that they are permanent, highly variable and visible, do not require invasive techniques or repeated handling of the animals, and involve little or no special equipment for application and monitoring. Permanent and non-invasive individual markings, such as body or tail color patterns, should prove to be particularly valuable for studying undisturbed snakes in the wild.

Acknowledgments.—Supported by the Arizona-Sonora Desert Museum, the University of Louisiana at Lafayette, NIH 1 F32 AR08590-01 to BRM, and NSF IBN 96-04698 to Kevin Conley. Bradford Hollingsworth, Travis LaDuc, Katherine Wadsworth, and two anonymous reviewers gave helpful comments on the manuscript. Katherine Wadsworth helped photograph the specimens.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 35, Number 1 (March 2004).

CAUDATA

CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS (Eastern Hellbender). **BREEDING SEASON**. The breeding season of eastern populations of *Cryptobranchus a. alleganiensis* has been fairly well documented in the literature. In general, the season lasts from mid-August through mid-September (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press. 587 pp.), although in Alabama it can continue into early October (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agri. Exp. Station. 347 pp.). Herein, we report what we believe to be the first documented records of gravidity and nesting from Georgia, perhaps the southeastern-most state within this salamander's range.

In an effort to collect skin mucous for bacterial analyses, we hand-captured *C. alleganiensis* at Cooper Creek, Union County, Georgia on 5 Sept 2002. Among the hellbenders captured were two gravid females, one of these discharged ca. five eggs when placed in a dilute solution of MS-222 to anesthetize the animal. Additionally, a nest guarded by an adult hellbender was discovered under a large flat rock. We immediately replaced the rock and did not collect either the eggs or the adult. We were not able to confirm the sex of this animal.

A previous collection trip to this same section of creek on 22 July 2002 yielded seven adult male and two adult female *C. alleganiensis*, none in reproductive condition.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@dnr.state.ga.us), **CARLOS D. CAMP, RICHARD M. AUSTIN, JR.,** and **R. ALEX PYRSON**, Department of Biology, Piedmont College, 165 Central Avenue, Demorest, Georgia 30535, USA, **LAINE GIOVANETTO, SEAN GRAHAM**, and **MELANIE MEADOWS**, Department of Biology, Georgia State University, P.O. Box 4010, Atlanta, Georgia 30302-4010, USA, and **DEAN DEMAREST**, United State Fish and Wildlife Service, 1875 Century Boulevard, Suite 240, Atlanta, Georgia 30345, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). **REPRODUCTION**. Detailed life histories are known for only a few populations of the *Plethodon glutinosus* complex and include several reports of egg clutches and very few reports of new hatchlings (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Smithsonian Instit. Press, Washington, D.C. 587 pp.).

On 24 Oct 2002, we discovered a female *P. glutinosus* (72 mm SVL) attending a newly laid clutch of eggs in Pettijohn Cave in Dickson Gulf on the eastern side of Pigeon Mountain, Walker County, Georgia, USA. The clutch was located in a horizontal crevice in the limestone rock of the cave wall ca. 1.3 m above the cave floor. It was suspended by a pedicel from the roof of the crevice and consisted of 17 eggs, each measuring 6.0–6.1 mm in diameter. The clutch was ca. 12 m from the cave opening. The outside air temperature was 16.5°C; the temperature inside the cave was 13.0°C. We monitored the clutch through the winter, revisiting it on 14 Dec 2002, 21 Jan, 9 Feb, and 1 March 2003. On 14 Dec 2002 the pedicel was broken, and the eggs lay in a heap on the floor of the crevice. The loss of suspension did not seem to interfere with development or the female's attendance. The significance of the 12-m distance from cave opening became apparent on cold days during the winter. The clutch was located at a depth closest to the opening where the thermal environment was relatively stable.

On 2 March 2003, one egg had hatched. The hatchling measured 16.4 mm SVL and 19.7 mm total length. Its belly was extended with yolk, it had distinct gills, and skin pigment was poorly developed. Because *Plethodon* hatchlings resorb their gills within a few days of hatching (Highton 1956. Copeia 1956:75–93) and because the other eggs seemed healthy and unhatched, we presumed that the hatchling was < 24 h old. Therefore, the gestation period was 128+ days.

This represents the latest seasonal dates of oviposition and hatching for the complex and >1 month later than those reported from caves in northern Alabama (Highton 1962. Copeia 1962:597–613). These were also the largest eggs and the longest gestation period reported for the *P. glutinosus* complex (Petranka 1998, *op. cit.*).

Submitted by **CARLOS D. CAMP**, Department of Biology, Piedmont College, P.O. Box 10, Demorest, Georgia 30535, USA (e-mail: ccamp@piedmont.edu), and **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@dnr.state.ga.us).

ANURA

BUFO PARIETALIS (Forest Toad)**. PREDATION.** Although the toxic secretions of toads are repellent against many predators, there are numerous reports for predators of toads throughout the world (Haddad and Rogério 1997. Amphibia-Reptilia 18:295–298). The population ecology and the natural predators of amphibians in the forest ecosystems of India are poorly studied. *Bufo parietalis* is a rare and little-known toad, endemic to tropical rainforests of the Western Ghats (Molur and Sally 1998. Zoo's Print 13[12]:29). Since 1999, we have observed the natural history of *B. parietalis* as part of population studies. Herein, we report predation by an invertebrate (mosquito) and a vertebrate (bird) on males engaged in reproductive activity in Karnataka, South India.

Herpetological Review

Volume 35, Number 2 — June 2004

Herpetological Review

The Quarterly News-Journal of the Society for the Study of Amphibians and Reptiles

Society for the Study of Amphibians and Reptiles

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2004 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Peabody Museum of Natural History, P.O. Box 208118, New Haven, Connecticut 06520-8118, USA. Fax: (203) 432-5176; e-mail: theodora.pinou@yale.edu

Future Annual Meetings

2004 — University of Oklahoma, Norman, Oklahoma, 26–31 May (with ASIH, HL)
2005 — University of South Florida, Tampa, Florida, 7–11 July (with ASIH, HL)

About Our Cover: *Saltuarius salebrosus*

With its slender limbs splayed astride the ochre stencil of an adult aboriginal hand, this Australian Leaf-Tailed Gecko (*Saltuarius salebrosus*) shows its true dimensions. At 14 cm SVL it is one of the largest of Australia's 112 described species of geckos.

The 13 named species of leaf-tailed geckos occur along eastern Australia between Sydney and Cape York Peninsula. They are currently placed in three allied genera (Couper et al. 2000. Mem. Queensland Mus. 45[2]:253–265; Hoskin et al. 2003. Austral. J. Zool. 51:153–164). Eight *Phyllurus* have cylindrical to flattened heart-shaped tails and a disruptive pattern of dark flecks; a single *Orraya* has a long neck, dark flecks and a fringe of spines around its flat original tail; and four *Saltuarius* have bold, lichen-like marbling and elaborately flanged tails.

Thirty years ago this complex of spectacular geckos were classified as only two species, both placed in *Phyllurus*. Some were simply assumed to be fragmented populations of one species, but most were overlooked because they occupy isolated rainforest blocks. Several are restricted to single localities. Taxonomic research on these geckos, most of it over the last decade, has helped shed light on the fragmentation of Australia's rainforests, the evolution of species in isolation, and the conservation value of seemingly insignificant stands of forest.

Leaf-tails are sedentary geckos that rely on stealth and concealment rather than speed (Wilson 2000. Austral. Geogr. Mag. 59:72–89). They emerge each evening from narrow rock crevices or cavities within the latticed trunks of rainforest fig trees, and rest head downwards a short distance from their shelter sites. They appear to maintain a strong site-fidelity, seldom venture far, and probably are long-lived. In the forested coastal ranges of mid-eastern Queensland, a cluster of four leaf-tail species in the genus *Phyllurus*, all named since 1993, occur side by side with no overlap in their distributions. The islands of rainforest they inhabit are as effectively isolated by woodland barriers, some less than 20 km apart, as they would be by an ocean.

The presence of these narrowly endemic species in apparently similar abutting forests, separated by seemingly trivial gaps of drier terrain, is an artifact of the expansion and contraction of Australia's rainforests (Couper et al. 1993. Mem. Queensland Mus. 34[1]:95–124). They are derived from a common ancestor but because they are now isolated, they have evolved into different species. It also illustrates the antiquity of their current isolation, the integrity of those small forest pockets, and the need, when planning development, to carefully consider each as a separate community.

Thanks to its association with a broader range of habitats than its relatives, *Saltuarius salebrosus* is the most widespread of the leaf-tails. In addition to rainforests it is also a rock dweller, occupying a band of granite and sandstone escarpments, caves, and overhangs from central to mid-eastern Queensland. The animal pictured, from the Blackdown Tableland, has a regenerated tail. The original tail is equally impressive, having a fringe of spines and a slender tip. Tail-loss in leaf-tails seems too common to attribute solely to predation attempts. With up to half of adults sporting regenerated tails it is likely that many are forfeited in disputes with rivals. Tails, you lose.

Steve Wilson is an Australian herpetologist based in Brisbane, Queensland. He recently co-authored (with Gerry Swan) Australia's first comprehensive reptile handbook, *A Complete Guide to Reptiles of Australia*. His next book, *A Field Guide to the Reptiles of Queensland*, is due for release in January 2005.

The gecko was photographed on Fuji Sensia 100 ASA film using an Olympus OM4Ti camera, a 50mm f3.5 macro lens, and an Olympus T10 ringflash.

SSAR BUSINESS

Dean E. Metter Memorial Award Application Deadline Extended Until 15 July 2004

The Dean E. Metter Memorial Award will be given annually by SSAR to a herpetology student. Its purpose is to encourage students to pursue field research in herpetology and to facilitate field research by providing funds for relevant expenses. Because this award has been so recently established, deadlines will be different for 2003 and 2004 ONLY. This year (2004), membership in SSAR must be paid no later than 1 July 2004 and proposals must be submitted by 15 July 2004. Proposals should be submitted electronically as e-mail attachments or by regular mail. Submit proposals or questions regarding application procedures to the Chair of the Metter Award Committee, Dr. Joseph J. Beatty (beattyj@science.oregonstate.edu). Awards will be announced on or around 15 August 2004.

Check the SSAR Web Site for submission instructions (http://www.ssarherps.org/pages/metter.html), background information, and format for the proposal.

Kennedy Student Award Committee Annual Report, 2004

The Kennedy Award Committee (Robin Andrews, Michael Dorcas, Terry Schwaner, Lynette Sievert, Robert Gatten, Jr., Chair) has completed its work for Volume 37 of the *Journal of Herpetology*. The Committee has selected "Testes size in Leptodactylid frogs and occurrence of multimale spawning in the genus *Leptodactylus* in Brazil" by **Cynthia P. de A. Prado** (student) and C.F.B. Haddad (Vol. 37: 354-362). The Kennedy Award carries with it a cash prize of US$200 or the winner's selection of any SSAR publications valued at twice that amount.

The committee invites all student members of the Society to submit their work to the *Journal*, and encourages regular members who supervise the work of students to draw this award to the attention of those students.

NEWSNOTES

12th Ordinary General Meeting of Societas Europaea Herpetologica

The 12th Ordinary General Meeting of European Herpetological Society (12thOGM SEH) was held in August 2003 in conjunction with the 2nd Ordinary Meeting of the A. M. Nikolsky's Herpetological Society under the Russian Academy of Sciences and North Eurasian Reptile Specialist Group of SSC IUCN. Approximately 360 delegates from 33 counties attended five days of meeting (12–16 August). Because of combined meeting of two societies there were many more participants than for previous SEH

meetings (176 persons in France in 1998, 148 persons in Cretea, Greece in 1999, and 86 persons in Slovenia in 2001). The meeting hall at the Zoological Institute was too small to accommodate this large turnout, and thus the main sites of the 12th OGM were the beautiful historical buildings of the St.Petersburg Branch of the Russian Academy of Sciences, St.Petersburg State University, and the Zoological Institute.

The purpose of this joint meeting was to promote mutual enrichment and further development of cooperation between both societies in the field of fundamental and conservation research. It enabled the research findings of Russian scientists to be presented in full, especially those relating to nature protection, in order that programs among the different countries of CIS and Europe can be articulated, with joint programs drawn up between Europe, the European part of Russia, and the Baltic region.

The meeting opened on the morning of 12 August in historical Big Hall of the St.Petersburg Branch of the Russian Academy of Sciences, made famous by many prominent events. This same venue hosted the Nobel Prize announcements in April 2003. Meeting participants were welcomed by Dr. Oleg Pugachev (vice-director of Zoological Institute), Academican Ilya S. Darevsky (President of A. M. Nikolsky's Herpetological Society under the Russian Academy of Sciences), and Dr. Natalia B. Ananjeva (President of the SEH, head of Department of Herpetology, Zoological Institute).

Plenary lectures followed: Ettore Olmo, Teresa Capriglione, Gaetano Odierna and Larissa Kupriyanova ("The contribution of cytogenetics to the study of reptiles systematics"), and Michael Shishkin ("On the patterns of evolution of the early Triassic herpetofauna in Europe and Southern Gondwana").

Two concurrent sessions of oral presentations began on the afternoon of the 12th, and continued during the balance of the meeting. Special sessions were held as follows: Molecular taxonomy and phylogeny of reptiles; Ecology and distribution of amphibians; Morphology and phylogeny of amphibians and reptiles; Ecology and conservation of amphibians and reptiles; Phylogeny and taxonomy of lacertid lizards; Ecology of arid reptiles; Urbanization effect, conservation and ecology of amphibians and reptiles; Speciation and population genetics of amphibians; Biogeography and ecology of amphibians and reptiles; Phylogeny, taxonomy and behavior of amphibians; Ecology and behavior of amphibians; Faunistics and systematics of reptiles. Four poster sessions were held with about 180 participants. Two workshops focused on the methods of variability evaluation and on the history of herpetology. During the latter workshop, a special poster was presented by Natalia B. Ananjeva and Igor G. Danilov to commemorate significant anniversary dates in Russian herpetology: 2003 was the anniversary year of prominent herpetologists Sergei Chernov, Paul Terentyev (100th Anniversary), and Lev Khozatsky (90th Anniversary).

Many presentations addressed problems of developing species protection strategies and putting these into practice, including problems related to importing and exporting herps. Considerable time was devoted to discussions of modern methods of molecular research and their role in the creation of gene banks.

On 14 August, whole day excursions enabled participants to see St. Petersburg sights during a tour of the city, and later, to visit Petershof parks and palas. A party took place on a boat on the Neva River from where it was possible to view St. Petersburg in the evening light.

Business meetings of SEH and Nikolsky's Society were conducted on 14 and 15 August, respectively.

Some publications in Russian were issued just prior to or in conjunction with the 12th SEH OGM, in addition to the 197-page book of meeting abstracts. The latter, in English, featured 291 abstracts and a database of addresses of all presenters (more than 540 persons), now available on the SEH website <www.gli.cas.cz>. The Russian-language publications are:

Modern Herpetology. Collected papers. Vol. 2. Saratov Univ. Press. N. B. Ananjeva et al. (eds.). 175 pp.

and two books edited by S. L. Kuzmin:

Kubykin, R. A. (compiler). 2003. Fascinating World of Reptiles. Moscow, Nauchnyi mir, 262 pp. + many color plates. The book contains chapters written by leading ex-Soviet herpetologists on reptiles of Middle Asia.

Russian translation (S. M. Lyapkov, translator) of the book**: Measuring and Monitoring Biological Diversity: Standard Methods for Amphibians** (W. R. Heyer et al., editors of the English edition). Moscow, KMK 380 pp.

—Submitted by Natalia B. Ananjeva

A Report on the Symposium on Turtle Origins, Evolution and Systematics Held August 2003 in St. Petersburg, Russia

and

GENNADY O. CHEREPANOV
Department of Vertebrate Zoology, St. Petersburg State University
universitetskaya emb. 7/9, 199034, St. Petersburg, Russia

An International Symposium on Turtle Origins, Evolution and Systematics was held at the Zoological Institute of the Russian Academy of Sciences (St. Petersburg) 18–20 August 2003. This symposium continued a tradition started 20 years ago by the First International Symposium on Fossil Turtles (Paris, 1983). Since then, there have been two sessions within larger meetings: one within the 75th Annual Meeting of the American Society of Ichthyologists and Herpetologists (Edmonton, 1995) and one within the 56th Annual Meeting of the Society of Vertebrate Paleontology (New York, 1996). Unfortunately, for political and later for financial reasons, Soviet and Russian specialists were not able to participate in any of these meetings.

FIG. 1. A group photo of some of the participants of the International Symposium on Turtle Origins, Evolution and Systematics at the Zoological Institute of the Russian Academy of Sciences. 1: S. Krasnova; 2: J. Claude; 3: V. Sukhanov; 4: G. Cherepanov; 5: A. Rezvyi; 6: V. Egorova; 7: D. Brinkman; 8: S. Kuratani; 9: W. Joyce; 10: S. Chapman; 11: V. Gillespie; 12: O. Piskurek; 13: E. Buffetaut; 14: I. Danilov; 15: J. Parham; 16: R. Hirayama; 17: Y. Ohya; 18: H. Tong.

FIG. 2. Walter Joyce gets acquainted with a specimen of *Anatolemys* (foreground) and the holotype of *Lindholmemys* (in box) as Igor Danilov (center) discusses some Russian literature with Ren Hirayama (left) and Don Brinkman (right) at the Chernyshev's Central Museum of Geological Exploration in St. Petersburg. Photo by James Parham.

Russia has a long tradition of turtle studies. L. G. Bojanus (1776–1827) published his famous "Anatome Testudinis Europaea" (1819, 1821), while he was rector of the University in Vilna (now Vilnius, Lithuania), then part of the Russian Empire. This work remains the most detailed description of turtle anatomy and was republished in 20th century twice (1902, 1970). Academician A. A. Strauch (1832–1893), Director of the Zoological Museum in St. Petersburg (now the Zoological Institute), is well known for his papers on chelonology (Strauch 1862, 1890). In fact, the term "chelonology," introduced by Polish turtle expert M. Mlynarski, was based on Strauch's (1862) "Chelonologische Studien" (Borkin, pers. comm.). W. A. Lindholm (? –1935) should also be mentioned among turtle experts of the beginning of the 20th century, although he is better known as a malacologist.

Large collections of fossil turtles from the territory of the Russian Empire, and later Soviet Union, are housed in St. Petersburg (Leningrad) at the Zoological Institute (ZISP) and at the Chernyshev's Central Museum of Geological Exploration (CCMGE). These collections were studied by A. N. Riabinin

(1874–1942), L. I. Khostazky (1913–1992), and L. A. Nessov (1948–1995). In the second half of the 20th century, turtle specialists appeared in other parts of the Soviet Union: Moscow (Russia), Kiev (Ukraine), Tbilisi (Georgia), and Almaty (Kazakhstan). Soviet chelonologists formulated important ideas about turtle phylogeny and systematics. Unfortunately, their ideas were not published in English and so were often ignored by foreign colleagues. Furthermore, the possibility of direct contact between Soviet and foreign scientists, and access to published materials, was limited. The 2003 international symposium on turtles in St. Petersburg aimed not only to solve scientific problems, but to establish close contacts between Russian and foreign turtle specialists (Fig. 1).

The Symposium was organized by an international team (Parham, Hirayama, Cherepanov), led by I. G. Danilov (ZISP). The scope of the symposium was expanded in comparison to previous ones to include problems connected with studying both fossil and recent turtles. The number of registered participants was 19, including scientists from Russia (7), Japan (4), France (3), USA (2), United Kingdom (1), Canada (1) and Georgia (1). This symposium was the largest by number of presentations (21). The age composition of participants was shared equally between young and middle generations. There were only two participants older than 60, V. B. Sukhanov (Moscow, Russia) and V. M. Chkhikvadze (Tbilisi, Georgia). It is worth mentioning that besides registered participants, sessions were attended by up to 50 additional people (colleagues from ZISP, students of the St. Petersburg University, and visitors). The official language of the Symposium was English. The welcoming speech was made by the Head of the Department of Ornithology and Herpetology of ZISP, N. B. Ananjeva. She noted that this Symposium took the baton from the XII Ordinary General Meeting of the Society Europaea Herpetologica, which had been just held in ZISP and SPSU (12–16 August 2003).

Besides the oral and poster presentations, an important part of the program was work with scientific collections of ZISP and CCMGE (Fig. 2). In the ZISP, work was conducted at the Department of Herpetology. Fossil specimens, including holotypes, and publications were made available. During those final days, one could find all the participants of the symposium sitting around a big table examining specimens, engaged in discussions with colleagues. Following the symposium, eight participants traveled to Moscow to visit the rich collections of the Paleontological Instititute (PIN).

The Program and Abstracts book of the symposium was published. The next Symposium on Origins, Evolution and Systematics of Turtles will be held in 2005 in Tokyo (Japan).

The organizers would like to express deep gratitude to Drs. N. B. Ananjeva, E. N. Kurochkin (PIN), V. B. Sukhanov (PIN), as well as administration and staff of the CCMGE for help in organization of the symposium. We thank L. Y. Borkin (ZISP) and Walter Joyce (Yale) for useful comments on this report.

Gopher Tortoise Council Grants

The J. Larry Landers Student Research Award is a Gopher Tortoise Council competitive grant program for undergraduate and graduate college students. Proposals can address research concerning Gopher Tortoise biology or any other relevant aspect of upland habitat conservation and management. The amount of the award is variable, but has averaged US $1,000 over the last few years. The proposal should be limited to four pages in length and should include a description of the project, a concise budget, and a brief resume of the student. Proposals should be submitted by 31 August 2004 to: Bob Herrington, Chair of Research Advisory Committee, Georgia Southwestern State University, Department of Biology, Americus, Georgia 31709, USA; e-mail: bherring@canes.gsw.edu.

Meetings Calendar

15–20 November 2004—VI Symposium of Zoology, Topes de Collantes, Sancti Spiritus, Cuba. Information: www.geocities.com/zoologiacubana/simposio or by e-mail: zoologia.ies@ama.cu.

16–18 January 2005—Biology of the Rattlesnakes conference, Loma Linda, California, USA. Information: www.BiologyoftheRattlesnakes.org.

OBITUARIES

Herpetological Review, 2004, 35(2), 100–101.

Walter John Breckenridge 1903–2003

JOHN MORIARTY
Bell Museum of Natural History, University of Minnesota
Minneapolis, Minnesota 55455, USA
e-mail: frogs@umn.edu

PHOTO BY BARBARA FRANKLIN

Walter John Breckenridge passed on May 23, 2003 at the age of 100. Breck, as he was known to his friends and colleagues, was Minnesota's premier naturalist. He was born on March 22, 1903 in Brooklyn, Iowa. After graduating form The University of Iowa in 1926, he moved to Minneapolis to work for Thomas Roberts at the Bell Museum of Natural History as a preparator/taxidermist. Breck's influence can be found in many of the museum's dioramas. He received his MA in 1937 for doing research on Marsh Hawks and his PhD in 1941. He became a curator in the 1930's and the director in 1946, remaining in that po-

sition for 24 years until his retirement in 1969.

Breck was best known in amphibian and reptile circles for his book, *Reptiles and Amphibians of Minnesota,* which was published in 1944. The book was a popularized edition of his 1941 Ph.D. of the same title. His book was the only reference for Minnesota for 50 years and was in print for 40 years. Breck's first herpetological paper was published in 1937 and over the next 30 years he authored or co-authored 29 more herpetological articles, including in-depth studies on Black-banded (Northern Prairie) Skinks, Canadian Toads, and Spiny Softshells. The Northern Prairie Skink work was the first detailed study on the life history of this lizard.

Professionally, Breck was more closely associated with the ornithological community. He was a life member of the Minnesota Ornithologist's Union. He published numerous papers on Minnesota birds and served as the President of the Wilson Ornithological Society. His ornithological accomplishments were honored by the creation of the Breckenridge Chair in Ornithology at the Bell Museum.

From the beginning of his career Breck established his reputation as an artist and illustrator. He drew all of the line drawings in his books and articles. His paintings were published in many books, including Thomas Robert's *Birds of Minnesota.*

Breck was a pioneer in wildlife photography. He went on to make a number of popular films including *Wood Duck Ways, Spring Comes to the Subarctic*, and *Migration Mysteries*. Breck traveled the country presenting these films as part of the Audubon film series. The Bell Museum has recently restored these classic nature films.

Breck is survived by his wife of almost seventy years, Dorothy, his daughter Barbara Franklin, son Thomas, five grandchildren, and six great grandchildren.

Conant studying a specimen of *Agkistrodon contortrix* in his laboratory at the University of New Mexico (1983).

On December 19, Roger Conant died peacefully in his sleep at the age of 94. He had been a regular contributor to North American herpetology since his first publication in November 1929. His last title, a major monograph on the garter snakes of transvolcanic Mexico, appeared just seven months before he died. In between, Roger produced a steady stream of notes, reviews, and papers punctuated by a dozen major works that mark his long career as one of the most distinguished of any American herpetologist of any generation. His volume in the Peterson Field Guides series, in its several editions, is the most widely-used book ever produced in our discipline. These alone would have assured his place as a major figure in the history of herpetology.

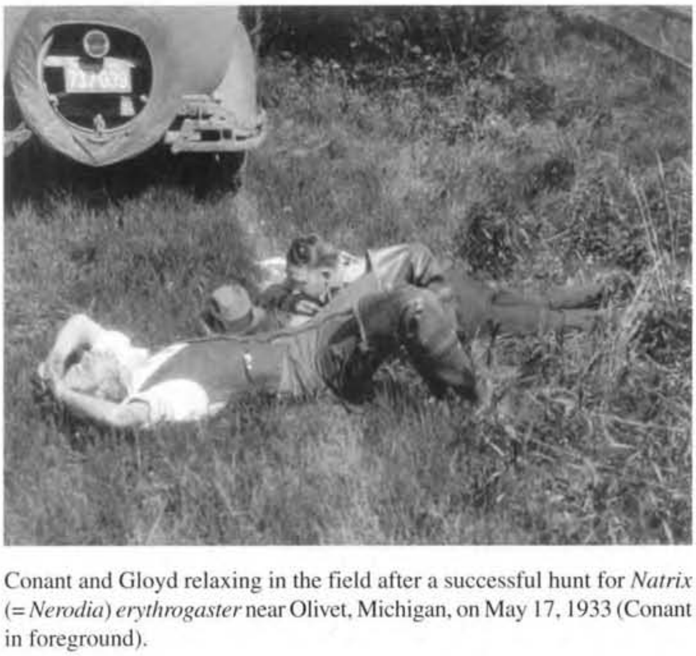
But the impact of Roger Conant was far greater than even these enviable contributions to the literature. He was one of the great zoo men of the 20th century. He impacted the lives of literally tens of thousands of young people through his authorship of the "Reptile Study" merit badge booklets (four editions, from 1944 to 1976) issued by the Boy Scouts of America. He also encouraged the budding careers of a multitude of would-be herpetologists, mostly teenagers and myself among them, by having the patience of Job to systematically answer every single letter sent to him over a period of some 70 years. His pride in this facet of his distinguished career is demonstrated by the fact that all of these letters were proudly displayed, bound in cloth covers, on a very long shelf in his Albuquerque library.

Roger was clearly not an ordinary herpetologist and this obituary, by a dozen of his closest colleagues, attempts to touch on some of the many aspects of his life and career in the hope that the younger herpetologists of today will understand the respect and even reverence that we of the older generation give to Roger Conant. It is my privilege, therefore, to begin this tribute with a brief summary of his remarkable life.

Roger Conant was born in Mamaroneck, New York, on May 6, 1909. His interest in reptiles, especially snakes, began at age 12 when he caught some water snakes at a boy scout camp. He quickly became so knowledgeable about snakes that he was soon giving lectures to scout troops and other groups. He briefly attended the University of Pennsylvania but had to drop out for financial reasons. Soon he had his first big break: to be hired, in 1929, as Curator of Reptiles at the Toledo (Ohio) Zoo. He was only 19. The reptile collection grew rapidly and soon Roger was General Curator (in effect, director) of the zoo. The Toledo period also represented his graduate-level training because Ann Arbor was nearby with its constellation of herpetologists at The University of Michigan—Ruthven, Gaige, and Blanchard and their many students. Roger regularly visited Ann Arbor and, among other beneficial interactions, he befriended a graduate student, Howard K. Gloyd, who became a close friend and lifelong colleague.

A formal portrait, taken in 1930 or 1931 by Howard K. Gloyd, when Conant was Curator of Reptiles at the Toledo Zoological Park.

In the 1930s, zoos generally did not have scientific programs, but Roger had unusually ambitious plans. As an adjunct to his zoo work—which included the design and construction of a new reptile house that is still used to this day—he decided to write a book, "The Reptiles of Ohio." To obtain the necessary specimens, he financed his own expeditions to all parts of Ohio (using an insurance payment for a doctor's bungled handling of a rattlesnake bite that cost him his left thumb). The voucher specimens he collected were kept in a makeshift museum at the zoo. The book, published in 1938 (and republished with revisionary addenda in 1951), was called "a landmark in the development of herpetology in the Eastern United States" by Karl P. Schmidt. Roger was now prominently on the national map. His monograph became the standard for state herpetologies and his basic format is still in use today.



Conant and Gloyd relaxing in the field after a successful hunt for *Natrix* (= *Nerodia*) *erythrogaster* near Olivet, Michigan, on May 17, 1933 (Conant in foreground).

Three years before the book was published, Roger moved to the Philadelphia Zoo as Curator of Reptiles. He later added other titles (Public Relations and Membership Secretary in 1936 and Director in 1967) and retired in 1973. Philadelphia Zoo was the first American zoo to exhibit live reptiles (1874), but Roger inherited an old building originally built for birds. Finally, in 1972, a new reptile house was opened, designed by him. It incorporated many modern features that have been widely imitated. Prior to its design, Roger visited many other facilities to get ideas and learn best practices. During his 38 years at the zoo, Roger pioneered some of the earliest captive breeding programs, developing combinations of diet and environment that also led to numerous longevity records for many species. He edited the zoo's publications for 28 years and wrote and conducted, for 33 years, a weekly radio show for the Philadelphia affiliate of NBC. He made frequent appearances on television to promote the zoo and an understanding of animals. Roger was not shy about his interests in animals and he had a commanding presence as a public speaker.

During Roger's Philadelphia years, his primary research interest was the systematics of water snakes, an interest that eventually led to Mexican expeditions (1949–1967) with his wife, Isabelle Hunt Conant, who was an outstanding wildlife photographer. In 1951, following preliminary correspondence, Roger Tory Peterson visited the zoo to ask Roger to write the volume on amphibians and reptiles in the field guide series that bears his name. Roger was the logical choice because of his prior publications and his prominence as a specialist on reptiles, but surely Isabelle's ability to take the photographs was a huge advantage since the book really required a team effort. They set out to illustrate every species and subspecies found east of the 100th meridian, so at one time or another they temporarily possessed examples of almost every one of them alive. Roger wrote the text and assembled the detailed and up-to-date distribution maps. Isabelle, with Roger's assist, made the photographs in black-and-white and then colored each one by hand with watercolor dyes, using the living specimens as her guide. The result, "A Field Guide to Reptiles and Amphibians of the United States and Canada," was published in 1958 and was an instant success. A second edition was published in 1975 but covered more territory to the west since

The Conants demonstrating their technique for obtaining photographs for use in the "Field Guide" (middle to late 1960s).

The Conants working in the shelter of their camper parked near the source of the Río Nazas in Durango, Mexico (September 1960).

Bob Stebbins's 1966 book on western herps extended only to the eastern borders of the Rockies. The new edition was appropriately retitled "Eastern and Central North America."

The third edition was issued in 1991. Together, these three editions represent the most widely used book in all of herpetology. More than half a million copies have been sold. In 1998, a "third edition, expanded" was issued in which Roger had virtually no part. He issued a public statement commenting upon what he called a "face lifting" perpetrated by his publisher simply to increase sales. He noted that there were color photographs added but no new text. He lamented the fact that pagination had increased from 450 to 616 pages and this, together with the use of coated paper, led to a much thicker and heavier book that was less a field book than the earlier versions. He publicly wondered if Peterson would be horrified. Clearly Roger was.

After retiring from the zoo early because of Isabelle's illness, they moved to Albuquerque where Roger had an adjunct professorship at the University of New Mexico. Here, devoid of his zoo duties, Roger could devote more time to herpetology. After Isabelle's death in 1976, there was a huge void in Roger's life and within weeks of her death he visited his old Ann Arbor colleague, Howard Gloyd, then living in Tucson. In 1932, they had mapped out a plan to monograph the pit viper genus *Agkistrodon*, a group of species found in Asia and in North and Central America, but it had been put aside for some years. Gloyd had sustained the renewed work since 1958 and Conant reentered the project in 1976. But Gloyd was terminally ill by this point and it was Conant, with the help of Gloyd's widow, Kathryn, who became Roger's wife in 1979, who completed this massive volume published by SSAR in 1990. I served as Roger's editor on this project. He would call me precisely at nine every Thursday morning, 7AM his time, over a period of three years, to talk about the manuscript, proofs, illustrations, and with digressions into everybody and everything herpetological. One reviewer, Jonathan Campbell, wrote, "This book is one of the few herpetological works that can truly be considered a 'classic' from the date of its first appearance." Roger thereafter modestly referred to it merely as his "heavy book." As part of his work to complete the book, Roger visited Costa Rica, Japan, China, Taiwan, Thailand, Malaysia, Indonesia, India, and Sri Lanka, in order to learn more about these snakes in their native habitats. It was my good luck to join him for the strenuous field work, in the middle of a typhoon, on Hainan Island off the Vietnamese coast in September 1985. He was 77 at the time.

Besides the various editions of "Reptiles of Ohio" and the "Field Guide" and the *Agkistrodon* volume, Roger published several other major works, including "What Snake Is That? A Field Guide to the Snakes of the United States East of the Rocky Mountains" (1939), "A Review of the Water Snakes of the Genus *Natrix* in Mexico" (1969), and his autobiography, appropriately titled "A Field Guide to the Life and Times of Roger Conant" (1997). The last-named title chronicles his long and exciting life in a series of chapters with headings like "Youthful Trials and Triumphs," "The Miracle at the Toledo Zoo," "Monkeys Invade West Philadelphia," "Acapulco, the Basilisk, and the Fiery Volcano," and "Hoodlums, Vandals, and Other Problems," among dozens of others. There are also vignettes of prominent herpetologists and zoo people who were friends of Roger's. This book is very nearly a history of North American herpetology in the 20th Century. The incredible detail recorded in this volume, even from Roger's teenage years, is testimony to the way in which he meticulously recorded every aspect of his fascinating life. This meticulousness extended to every aspect of his life including, most especially, his scientific contributions.

Besides his research, Roger gave freely of his time to numerous organizations. He edited the zoo section of *Parks and Recreation* magazine for 20 years and served as both secretary and, later, president of the Association of Zoological Parks and Aquariums. He held several prominent positions, including president, in the American Society of Ichthyologists and Herpetologists and chaired the important ASIH committee that began the standardization of English names for the amphibians and reptiles of the United States and Canada. He served on the Board of Directors of SSAR, but it was his book, "Reptiles of Ohio," that influenced the early development of The Ohio Herpetological Society, SSAR's predecessor organization, in the late 1950s. His book was a kind of bible that inspired the early officers of OHS, then mostly high school and college students, to do serious field research and he served as an unofficial adviser during the early years of OHS. Some have even referred to him as the society's godfather and he was invited to

With early officers of The Ohio Herpetological Society (the precursor to the Society for the Study of Amphibians and Reptiles), gathered for the society's 25th annual meeting in Raleigh, North Carolina (August 1982). *From left*: Kraig Adler, Ray E. Ashton, Jr., Paul M. Daniel, Stephen G. Tilley, David M. Dennis, Barry D. Valentine, Roger Conant, Corson J. Hirschfeld, Joseph T. Collins, Ronald A. Brandon, and Henri C. Seibert.

join the present and former officers who gathered in 1982 to celebrate the 25th anniversary of OHS–SSAR.

Among his many honors, surely the most meaningful to Roger was the honorary Doctor of Science degree awarded to him by the University of Colorado in 1971. For someone who was not able to complete his undergraduate degree, this recognition of his professional career by his academic colleagues was very special indeed. In 1989, his zoo colleagues also honored him, with the R. Marlin Perkins Award for professional excellence, for his example of combining serious research with the more usual duties of a zoo curator. This has had a transformative effect on bridging the gap that separated zoo staff from their academic colleagues in universities and museums. He also received the Distinguished Service Award from the National Recreation and Park Association. Among his most recent awards are these: Gold Medal for Natural Resource Conservation (Boy Scouts of America, 1999), Cardinal Award (Ohio Department of Natural Resources, 1999), Herbert Osborn Award (Ohio Biological Survey, 2000), Hall of Fame (Ohio Department of Natural Resources, 2001), and the W. Frank Blair Eminent Naturalist Award (Southwestern Association of Naturalists, 2003).*

Roger Conant's life has been an inspiration to generations of herpetologists in North America and beyond, and it will stand as an example for years to come. Besides his many scientific contributions to herpetological science and to zoo development, perhaps his most important impact was the encouragement of thousands of young people to develop careers in herpetology, biology, conservation, and related fields.

Each career is unique, but Roger's was truly unusual and special. Its impact on our field has been immense and broadly felt. It is hard to imagine that we will ever see another whose influence on our discipline will be so profound as Roger's has been. I now yield to my collaborators to explain the special ways in which Roger influenced them as a colleague or as a mentor. For me, he was both, and also a dear friend, as he was to so many others. He will be very deeply missed by us all and by legions of others he did not personally know.

* These awards are given in some detail since they occurred after the publication of Roger's autobiography. For this information, I am grateful to Raymond Novotny, who organized the documentation leading to the nominations for these awards.

I had extensive correspondence with Roger Conant long before I ever met him. One matter of mutual interest was the taxonomy and distribution of snakes of the genus *Pituophis*. In 1947, I was employed by the U.S. Fish and Wildlife Service. Roger was aware of my herpetological activities in California, and when I moved to Louisiana, he wrote to me with an urgent request that I be alert for Louisiana pine snakes (*Pituophis melanoleucus ruthveni*). I was already aware of this rare snake and keenly interested in finding some. I lived with my family in Leesville, but every day I drove to the national forest, where my studies involved mainly white-tailed deer, but also were concerned with armadillos, bobwhite, mourning doves and other birds, and their effect as seed-eaters on longleaf pine regeneration. The long daily drive on little-used roads improved my chances of finding snakes. I identified and recorded all that I saw.

I found one *ruthveni* on the road before my correspondence with Roger. I preserved it and sent it to Klauber. Subsequently I found two more and sent them alive to Roger. I found the dried carcass of a fourth one but did not preserve it. In 1956, Roger published a paper based on my two *ruthveni* and a few records of *lodingi*, the black pine snake from near Mobile. In this paper, Roger quoted my field notes at length.

The relationships among pine snakes of the eastern states, the bull snake of the Great Plains, and the gopher snakes of western states have been controversial, and their scientific names have been unstable. *Pituophis melanoleucus ruthveni* was named by Stull (a doctoral candidate at the University of Michigan) in 1929 from two specimens from Rapides Parish, Louisiana. In 1935, Burt mentioned a third specimen from Zavalla, Angelina County, Texas. Few were known at the time of my collection. In Roger's 1956 paper, he mentioned three localities from Natchitoches Parish, Louisiana, one locality in Rapides Parish, and four from Vernon Parish, and referenced five localities in Texas.

The Louisiana pine snake, *ruthveni*, was stated by Conant in 1956 not to intergrade either with the *melanoleucus* subspecies nor with *sayi* on the west. But in several editions of the List of Common and Scientific Names, all U.S. *Pituophis* were considered conspecific under the name *melanoleucus*. In 1995 however, Reichling concluded that *ruthveni* is indeed a distinct species, as advocated long ago by Conant. It must be acknowledged that all his writings are exemplary samples of scientific writing, characterized by logic, clarity, and brevity.

—*Henry S. Fitch*

When I was a kid, Ditmars and Conant, at least their writings anyway, were my constant herping companions. And so when I discovered a strange looking salamander in a neighbor's swimming pool, I consulted my dog-eared copy of the Conant *Field Guide*. The lucid, friendly text was easy for me to follow, and I concluded, with growing excitement, that I had found something extraordinary: a Jefferson Salamander. Up in Saint Louis, this would have been unremarkable, but I lived in Memphis, where this species had never been seen.

What to do? Somehow, I knew that Roger Conant was Director of the Philadelphia Zoo, so I summoned my courage and telephoned him. He was not available, but his secretary, no doubt a veteran of such calls, instructed me to send the specimen to the zoo. I packed the little salamander with the utmost care and dropped it into the mail. Several days later the phone rang and a voice at the other end requested that I hold for Dr. Conant.

I held my breath. Time stood still. But soon I found myself talking with a cheerful person who treated me as a colleague. Conant praised my packing job and informed me that the salamander had not only arrived in splendid condition, but was already feeding! More importantly, he confirmed my suspicions by agreeing with my identification! I walked with giants.

Conant told me he was sending the specimen to Tom Uzzell, who at the time was doing biochemical research on salamanders. After the call, I realized I liked Roger Conant. He was friendly, enthusiastic, and obviously very wise. When Uzzell's analysis was final, I received another call from Philadelphia. This time the news was perplexing to both of us. Uzzell had found that it was simply an aberrant Small-mouthed Salamander, a species utterly commonplace in West Tennessee. Oh well.

So began a friendship that ran for decades. It brought me excellent advice on everything from herps to politics. I worked for several years with Roger on his memoirs, and was treated to weekly, marathon phone calls in which he shared anecdotes about many of the great herpetologists he had known. I listened in awe, and encouraged him to include as many as were fit to print in his book. He did, and his autobiography ranks as a history of twentieth century herpetology in America. My time at the Conant house in Albuquerque is one of my fondest memories.

Roger inspired me with his orderly approach to work and life. He never lost sight of his passion: the reptiles and amphibians. That focus kept him modest and accessible while his professional awards multiplied. He was a chivalrous gentleman who hailed from an era that produced real leaders. I am honored to have been associated with Roger Conant as a herpetologist, but I am proudest to have had him as a friend.

And by the way, we agreed to the end that the little salamander was a Jefferson.

—*William W. Lamar*

Roger Conant had a huge impact on me as a budding herpetologist in the early 1960s through his 1958 *Field Guide to Reptiles and Amphibians*. Like many other young people, it served as a cornerstone of my passion and later my career. As a professional, I interacted with Roger through his editing of my papers (including one co-written with him) and discussions over things herpetological. I was always struck by his meticulous editing and writing skills, paying close attention to the smallest of details. He was one of my mentors.

Although I had first met Roger briefly in 1982, I came to know him and his wife Kathryn Gloyd in September 1989 at the First World Congress of Herpetology in Canterbury, England. Along with another 40 or so colleagues and spouses, my wife and I had booked the, as it turned out, infamous one-day bus trip to Paris. All of us were destined to spend a very long day on that bus. It left at about 0600, taking the ferry across the English Channel from Dover to Chalice, France, arriving in Paris after several hours on the road in mostly hard rain. We had three hours more on the bus in Paris seeing the sights, stopping twice briefly, once at the Eiffel Tower and again at the Notre Dame Cathedral. Coming back required another ferry ride, but this time it was in rough seas. All of us well remember the large ferry boat riding the huge waves and the smacking sound that the propellers made when they emerged from the water as they broke free of each crest. Roger had a problem with his balance and I stayed with him on that voyage, helping him move around when he needed to change locations. Many friendships were solidified on that bus trip and Roger and I were fast friends when we finally got back to Canterbury close to midnight.

In 1991, I had the privilege of assembling and binding a set of letters written to Roger by numerous friends, family, colleagues, and students. I presented them to Roger at a reception following a two-day symposium in his honor at the SSAR meeting at Pennsylvania State University. Reading these letters showed me just how much he was appreciated and loved for all the attention and mentoring he provided for just about everyone throughout his life. These included people from the zoo world, herpetologists, and many others. Several of the letters were from people to whom he had given time while a busy zoo curator and director when they were young.

I visited Roger in Albuquerque at the end of 1991 and rode with him in his Volkswagon bus to Tucson during 2–3 January 1992, stopping by my master's thesis field site south of Willcox along the way. He was 82 at the time and insisted on driving the entire way, although we had to make it a two-day trip so he could rest overnight at a hotel near Deming. I had volunteered to help pack up the Howard K. Gloyd personal library then housed at Kathryn Gloyd's condo. Kathryn and Roger had given it to the University of Texas at Arlington (UT-A). They were doting hosts and kept me well fed at local restaurants; they frequently ate out. Much of the time spent with Roger on that trip was devoted to discussions of the history of herpetology and focused particularly on biographical information of people he had known well, such as H. K. Gloyd and E. R. Dunn. After three days of packing books, correspondence, and other materials, I drove the Gloyd library in a U-Haul truck to the Dallas–Fort Worth area 6–7 January. The collection is now at UT-A under the watchful eye of Jonathan Campbell.

Roger was a true friend and colleague, and encouraged me many times to be the best person I could be. I certainly benefited from his field guide when I was young and from his mentoring later in my professional life. My memories of him will be largely of those days late in his life in Albuquerque and Tucson, and on the ride in his VW bus between them, when we talked about herpetology and its history.

—*Joseph C. Mitchell*

A few years after I started my career at the Dallas Zoo in 1966, the American Zoo and Aquarium Association held a regional meeting in the Dallas–Fort Worth area. Since there were large herpetological collections at the two zoos, it seemed logical to invite a number of prominent herpetologists to present papers and interact with the delegates. Included in this stellar group were Roger Conant and Edward H. Taylor from the University of Kansas. I invited both of them to stay at my home.

Each morning as I dragged myself out of bed, the strains of operatic arias emanated from my stereo. Roger and Ed would be sitting in the living room eating graham crackers, drinking coffee, and reminiscing about their careers in herpetology and adventures in the field. Every evening, I invited colleagues and friends to my home and we sat spellbound as these two great herpetologists told us about their herpetological experiences and their favorite places, especially Mexico. It was a remarkable week.

Some years later, we hatched gray-banded kingsnakes and Trans-Pecos ratsnakes at our zoo. Roger was director of the Philadelphia Zoo and I asked him if he would like some of these baby snakes for his zoo collection. He accepted with enthusiasm and we sent these reptiles in cloth bags in a wooden shipping crate. Several weeks later, Roger returned our crate and I was surprised to find the bags laundered, neatly pressed, and folded. I called him to express my amazement at the pristine state of these bags—he said that it was the only way that bags should be returned. It must be said that Roger was the only one to ever return clean bags!

Thirty years after I started in Dallas, I decided to retire and move to Washington, DC. I was apprehensive as horrific stories about lethargy, boredom, and depression after retirement permeated my brain. Clearly, I needed advice and counsel if my retirement was to be pleasant. I asked Roger if he could share his thoughts about successful retirement. His first rule was that one always needed to have a future project in mind. His second was to ensure that the preceding day and the following day are different from the present day. He lived by this philosophy—last year, as proof of his continuing productivity, he sent an inscribed copy of his recently completed monograph on Mexican garter snakes published by the American Museum of Natural History.

It will be unlikely, even amazing, if our profession ever produces another Roger Conant. He was my confidant, mentor, and friend—I will miss him.

— *James B. Murphy*

On my birthday in 1959 I received a copy of Roger Conant's field guide. This magical guide to amphibians and reptiles, full of detailed information and wondrous illustrations by Isabelle Hunt Conant, was to have an immeasurable impact on my youth, just like it did in the lives of so many others.

In 1968, J. R. McCranie and I found an axanthic cornsnake west of Miami. Cornsnakes lacking red pigment were a rarity in those days, and since I was soon traveling to Philadelphia on business I brought the snake along, chancing the opportunity to meet and show it to the Conants—and I did. I met Roger and Isabelle in their historic Penn House office at the Philadelphia Zoo. After a brief introduction, I pulled the snake from a bag and Dr. Conant replied, "That's an unusual Pilot Black Snake you have there," but as I turned the snake over to reveal its checkerboard belly he gasped, "Oh my!" That day Roger Conant took time from his busy schedule to show me around the zoo. This fortuitous rendezvous was the start of a close relationship that was to last for three and a half decades.

In the years that followed I sent the Conants a few introduced reptiles from Florida, for photographs in the second edition of their field guide. After Isabelle and H. K. Gloyd passed away, Roger called to request photographs of various *Agkistrodon* for the upcoming Gloyd and Conant

monograph. Because I am a native Costa Rican, our discussion turned to *A. bilineatus* in the region, which at that time was poorly known. In early 1982, in the company of a mutual friend, G. W. Schuett, Roger and I decided to travel to Costa Rica in search of specimens.

Roger Conant was a great storyteller. During that trip Schuett and I bombarded Roger with questions, asking him what herpetology was like in the "early days," and for insight into the personalities of numerous herpetologists who came before our time. Roger responded by showering us with tidbits of herpetological history, but the real pearls came late at night—just before bedtime. Each night he told us a story, and every morning we awoke to find Roger writing diligently in his notebook. At the time, we didn't know Roger was busy jotting down the story from the night before, and a few months later, much to our surprise, we received a booklet in the mail published by the Toledo Herpetological Society and entitled *Herpetology in Ohio—Fifty Years Ago*. Mine was inscribed with: This "Bedtime Story Book" is inscribed with fond memories of a wonderful two weeks in Costa Rica.

According to Roger, our eagerness to learn about the past was the incentive he needed to begin serious work on his memoirs. His exhaustive autobiography, published by Selva in 1997, leaves us a detailed accounting of his life and accomplishments, but it also contains a treasure-trove of historical information, herpetological and otherwise. Because of my involvement in the publishing business, how fortunate I was to share in Roger's joy when presenting him with the first copy!

As a giant in herpetology, no doubt many will be writing about Roger Conant's amazing organizational skills, attention to detail, literary contributions, lifelong productivity, and so on. From a personal perspective, however, Roger was my friend, mentor, and father figure. He enriched my life in so many ways, and it would warm his heart to know that by simply following his example, he will continue to do so.

—Louis W. Porras

My memories of Roger Conant span over two decades, and it was my good fortune to have known him as a colleague and friend since the beginning of my scientific career. In the late 1970s, as an undergraduate at the University of Toledo, I spent most of my spare time at the Toledo Zoo, and primarily in the Reptile House. At that time Bill Dennler was the newly appointed Curator of Reptiles, and he was most generous in allowing Fred Kraus, Jeff Cook, and me to volunteer our services behind the scenes. Although I knew of Roger Conant by way of the Boy Scouts (Reptile Study Merit Badge) and his field guide, during those volunteer sessions I became more familiar with his research and zoo legacy. In 1929, when Roger was merely 19 years old, he held his first official position in herpetology as Curator of Reptiles at the Toledo Zoo. That important time in his life is chronicled in his memoirs.

Bill regularly encouraged bull sessions in the kitchen of the Reptile House which often entailed discussions of the "early days" at the Toledo Zoo and the challenges Roger Conant faced as a young curator. Because of our keen interest in the local herpetofauna, we discussed Conant's "extra job"— surveying the reptiles of Ohio. This work resulted in Roger's classic, *The Reptiles of Ohio*. Fred Kraus and I were particularly enthusiastic of that publication, since we would soon embark on a survey of the herpetofauna of the coastal zone of western Lake Erie. Conant's work was absolutely essential to us, and we fittingly dedicated our manuscript to him. Those were mighty good days.

During those lively discussions at the zoo, I could have never imagined that a few years later I would be invited to assist Roger in hunting cantils (*Agkistrodon bilineatus*) in northwestern Costa Rica. That unexpected opportunity, arranged by Louis Porras, allowed me to work in the field side-by-side with one of our country's foremost experts in herpetology and world authority on a group of snakes (*Agkistrodon*) for which we shared a passion. Costa Rica was my second foray to Central America, but surprisingly it was Roger's first. He was like a kid in a candy store! Each day as we prepared for the field, his eyes lit up with excitement in anticipation of searching for the elusive "Castellana." Although we were unable to secure live individuals we did not return to the States empty handed. Through the kind gesture of the Instituto Clodomiro Picado, preserved specimens were given to Roger for his use. He was stunned. On our return to our hotel in Liberia, Roger expressed his sheer joy by shouting colorful expletives that I never heard the likes from him again! At that time, I was shocked that someone could become so excited over a few dead snakes. I learned so much from that experience.

Publication of the Gloyd and Conant *Agkistrodon* opus was a great moment in herpetological history, and it was a tremendous honor to assist Roger in various ways. At his insistence, my wife Laura completed over a dozen delineations for the "heavy book" (as Roger called it)—he loved her art.

In reflection, I have no doubt that Roger Conant possessed genius. His was not displayed in eccentric mannerisms and arrogant actions, but in a subtle and quiet ability to collect, organize, and process information for large-scale projects. In his research, each and every detail was painstakingly considered. Roger's vast achievements are even more remarkable knowing that he was largely self-educated. If genius is measured by the degree to which one's ideas and work influence others, Roger stands among the giants of knowledge.

Cheers to you, Roger, to your remarkable and enviable life.

—Gordon W. Schuett

Roger was an adjunct professor at the University of New Mexico when I arrived there in 1974. At that time, he was hard at work on the third edition of his eastern field guide to reptiles and amphibians. When that was finished, he tackled the *Agkistrodon* monograph that he and Howard Gloyd were writing. Howard died when the manuscript was still embryonic and Roger, aided by Howard's widow and his own wife-to-be, Kathryn, saw it through to completion. He had me read the final draft. As in all of Roger's work it was almost impeccable, and I was able to find only one or two minor errors. Next came the monograph on the garter snakes of the lakes of the Mexican plateau, based on collections that he and Isabelle made in the mid 1900s. My wife and I revisited many of these lakes and were able to confirm that the *Thamnophis* were still present in several of them. He finished that work after I left New Mexico in 1993.

Roger and I became good friends during the 18 years I was there. My main impression of Roger is that he was completely goal-oriented. He moved from one large project immediately to the next one. Health problems slowed him down at times, but his results testify to his staying power. He worked in the mornings, and always took a nap in the afternoon. When he came over to the Museum of Southwestern Biology, we would talk of mutual interests, especially in the systematics of snakes and the enduring values of museum collections. Roger never learned modern techniques of systematic analysis, but I am sure that his garter snake monograph, based on classical morphological techniques, will stand the test of time.

—Norman Scott

The long career of Roger Conant overlapped my own almost completely. He was born three years earlier. His first publication came in 1929, mine in 1931. His first new taxon was described in 1934, mine in 1935. Other parallelisms followed. Circumstances dictated, however, that his academic life would be short; he had but two years at the University of Pennsylvania. The beginning and end of his professional life was with zoos, where academic degrees did not limit achievement, at that time. The eminence he achieved during his lifetime might never have been possible within the constraints of academia.

Nevertheless, there are constraints in zoo administration, too, but he rose above them to become far more productive than most academics,

both scientifically and in promotion of familiarity of the general public with especially amphibians and reptiles, but also with a wide variety of other animals.

Thus the circumstances that led to my perennial academic life did not lead to direct contacts with Roger until the early 1940s, when we both had developed a great interest in the herpetology of Mexico. He was then interested in a monograph of it, but in deference to my own efforts he left the field to me. I will always wonder how much better a job he would have done with it, for he has always represented the ultimate in perfectionism.

It was a great occasion when we arranged for Roger to receive academic recognition with a Doctor of Science degree from the University of Colorado in 1971. It was a degree earned many times over for accomplishments in each of the academic areas of performance: research, service, and teaching. Very few other academics match his excellence in all those areas.

—Hobart M. Smith

Despite our lengthy and close association by correspondence, chiefly in relation to our eastern and western field guides, Roger Conant and I met in the flesh only five or six times. This happened at scientific meetings. I'm deeply thankful for these occasions.

My most vivid memory of him occurred at the 52nd annual meeting of the American Society of Ichthyologists and Herpetologists in Boston in 1972. Society members were housed in a tall building. A fire-alarm sounded and people poured out of the building. I soon found many of my friends, but where was Conant? Finally, he appeared bearing an arm-load of his precious maps for the eastern field guide. He brought them to meetings for updating with the help of colleagues. There was no way he would leave them, even at the risk of being cooked!

Roger was a man of great devotion—to his wife, his research, his directorship of the Philadelphia Zoo, and to his friends. He helped me immensely as I began work on my own field guide to the reptiles and amphibians of the West, including allowing me to use his map plates for my guide. In one of his letters to me, he wrote that the best thing he ever did in his life was to marry Isabelle. He always spoke of the great pride he felt in her artistic talents and that he was sorry that her pictures had to be so small because of the many species to be covered by the eastern guide.

I will remember Roger as one of the great men of our time, not only because of his scientific accomplishments, but also for his important contributions to the nature education of the general public.

—Robert C. Stebbins

Shortly after I arrived at the American Museum of Natural History late in June 1954, Chuck Bogert took me to meet Roger and Isabelle at their home in Taunton on the edge of the New Jersey Pine Barrens. This initiated a friendship lasting nearly 50 years. How welcoming they were to a young herpetologist very much out of his element in the East! And how wonderful it was to be introduced by an expert to such a place as the Pine Barrens.

Roger's long relationship with AMNH as a Research Associate in Herpetology assured a continuing professional and personal friendship. Later, with both of us retired and established in the Southwest, we saw one-another in Albuquerque or Tucson scarcely less often than when we both lived in New Jersey. Looking back, I think that what I most admired in Roger was the energy and drive that enabled him to combine a distinguished career as a zoo curator and director with an output of research and popular publications that would be the envy of many colleagues.

—Richard Zweifel

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Origin of Venom in Snakes

The wide distribution of Duvernoy's glands and differentiated maxillary dentitions across colubroid lineages suggests that toxic secretions are a synapomorphy of Colubroidea. The authors isolated and compared a polypeptide toxin from the Duvernoy's secretion of the Asian ratsnake *Coelognathus radiatus* with toxins of other snake taxa. The isolated toxin was named α-colubritoxin, and represents the first colubrid toxin for which the complete amino acid sequence has been obtained. This sequence was aligned with several elapid 3FTX sequences in CLUSTAL-X and phylogenetic analyses using Bayesian inference were performed. The authors found that α-colubritoxin is part of the three-finger toxin (3FTX) family, which was thought to be unique to elapids. Moreover, toxins with similar molecular weights were detected in several other colubrid taxa. These results suggest that this toxin family originated early in the evolutionary history of advanced snakes. In addition, the absence of 3FTXs in viper venoms supports the basal phylogenetic position of vipers among colubroids.

Fry, B. G., N. G. Lumsden, W. Wüster, J. C. Wickramaratna, W. C. Hodgson, and R. M. Kini. 2003. Isolation of a neurotoxin (α-colubritoxin) from a nonvenomous colubrid: evidence for early origin of venom in snakes. Journal of Molecular Evolution 57:446–452.

Mitochondrial Diversity in Malagasy Poison Frogs

With 17 species, Malagasy poison frogs *Mantella* are among the most prominent representatives of the endemic fauna of Madagascar. One of the clades within *Mantella* is the *M. madagascariensis* group, which is characterized by a high diversity in color phenotypes. The authors used 2.8 kbp of three mitochondrial and one nuclear gene of 15 *Mantella* species to study the phylogenetic relationships among the five species included in the *M. madagascariensis* group. Sequences were aligned with CLUSTAL-X and partition homogeneity was tested using the ILD test. Analyses included maximum parsimony, maximum likelihood, Shimodaira-Hasegawa tests, bootstrapping, and Bayesian posterior probabilities. These analyses supported the monophyly of the

M. madagascariensis group. In addition, haplotype variation in the cytochrome *b* gene among and within seven populations of the group also was examined. Haplotype networks were constructed, and analysis of molecular variance was performed to determine hierarchical structuring of genetic variation. The authors found a relatively high haplotype diversity within populations of the *M. madagascariensis* group. Because quaternary records suggest periods of fluctuating climate in parts of Madagascar, the authors hypothesized that Malagasy poison frogs have been repeatedly isolated in small refugia with subsequent range expansion and intensive introgression in contact zones.

VENCES, M., Y. CHIARI, L. RAHARIVOLOLONIAINA, AND A. MEYER. 2004. High mitochondrial diversity within and among populations of Malagasy poison frogs. Molecular Phylogenetics and Evolution 30:295–307.

The Middle Ear of *Rana catesbeiana*

The tympanic cavity mainly conducts middle and high sound frequencies in anurans. The author studied the morphology and functional role of the middle ear in *Rana catesbeiana*. Audiograms were obtained from nine adult frogs by stimulating the intact ear from the outside. Thereafter, middle ear structures were removed and a second round of audiograms was obtained by stimulating the amputated columella. Differences between these audiograms indicated the mechanical role of the structures removed. Werner found that the extracolumella and columella of the American bullfrog are distinct units jointed at an angle with potential motion. Moreover, he noticed that this ossicular chain included a mechanical lever and was able to confirm this lever action with physiological experiments.

WERNER, Y. L. 2003. Mechanical leverage in the middle ear of the American bullfrog, *Rana catesbeiana*. Hearing Research 175:54–65.

Sensory Drive and Dewlap Design in Anoles

Signal diversification might play an important role in promoting species richness of taxa characterized by rapid and intensive speciation. The sensory drive hypothesis has been proposed as a mechanism leading to signal diversity between closely related species. Under this hypothesis, species or populations come to occupy different habitat conditions where selection for effective communication promotes divergence in signal designs. The authors used four allopatric populations of *Anolis cristatellus* from mesic and xeric habitats in Puerto Rico to test whether the process of sensory drive can take place at the population level. They measured total intensity and spectral quality of the light at each location, as well as spectral transmission and reflectance properties of male dewlaps. Leal and Fleishman found that dewlaps from mesic populations reflect more light than dewlaps from xeric populations, and that the relative detection probability of dewlap design was affected by habitat light conditions. These and other results suggest that sensory drive might be an important mechanism in the dynamics of the speciation process in anoles.

Evolutionary Significance of Oral Morphology in Carnivorous Tadpoles

Asian-African tiger frogs (*Hoplobatrachus)* have carnivorous tadpoles with peculiar oral features, such as keratinized spurs on the buccal floor. Based on a molecular phylogeny and detailed morphological descriptions, the authors studied the evolution of larval oral morphology in these frogs. Phylogenetic analyses included 2430 bp of two nuclear and four mitochondrial genes and corroborated monophyly of *Hoplobatrachus*, with *Euphlyctis* as sister taxon. Carnivorous specializations in tadpoles of *Hoplobatrachus* could explain why this taxon has been so successful in adapting to arid environments where ponds are at high risk of desiccation. Grosjean et al. hypothesize that evolution of carnivorous tadpoles was the key innovation that enabled *Hoplobatrachus* to disperse into its present wide distribution area in Asia and Africa.

GROSJEAN, S., M. VENCES, AND A. DUBOIS. 2004. Evolutionary significance of oral morphology in the carnivorous tadpoles of tiger frogs, genus *Hoplobatrachus* (Ranidae). Biological Journal of the Linnean Society 81:171–181.

Female-Biased Dispersal in *Rana catesbeiana*

The mating system of the North American bullfrog is well characterized, yet little is known about its dispersal behavior and patterns of gene flow. Using data from seven polymorphic DNA microsatellite loci, the authors studied sex-biased dispersal patterns in *Rana catesbeiana* based on two predictions. First, philopatry should benefit males by allowing familiarity with local reproductive resources, and second, greater dispersal by females should occur, which reflects the importance of mate choice in inbreeding avoidance and reproductive success. Frogs were sampled from nine locations within the Frontenac Axis region of eastern Ontario, where populations share a common postglacial history. The authors found some evidence for female-biased dispersal in bullfrogs.

AUSTIN, J. D., J. A. DÁVILA, S. C. LOUGHEED, AND P. T. BOAG. 2003. Genetic evidence for female-biased dispersal in the bullfrog, *Rana catesbeiana* (Ranidae). Molecular Ecology 12:3165–3172.

Evolution of Aposematism and Diet Specialization in Dendrobatid Frogs

The Neotropical family Dendrobatidae includes approximately 210 species. Some of these are brightly colored and toxic, whereas others are cryptic and nontoxic. Thus, dendrobatids are ideal organisms to study the association of unprofitability with a warning signal (i.e., aposematism) in an evolutionary context. Based on mtDNA data from a broad taxon sample of cryptic and aposematic species, the authors performed phylogenetic and statistical analyses to study the evolution of aposematism and diet specialization in dendrobatid frogs. Contrary to what had been suggested in previous studies, Santos et al. found that the association of conspicuous bright coloration and toxicity appeared several times. In addition, evidence is presented that diet specialization has occurred more than once, and is associated with the multiple origins of conspicuousness and toxicity. According to the authors, these results suggest parallel and correlated evolutionary trends toward specialization.

Santos, J. C., L. A. Coloma, and D. C. Cannatella. 2003. Multiple, recurring origins of aposematism and diet specialization in poison frogs. Proceedings of the National Academy of Sciences 100:12792–12797.

Xenopus Might Help Understanding Alzheimer's Disease

One of the central features of Alzheimer's disease (AD) in its late stages is the specific loss of neurons that seems to depend on amyloid α-peptide deposition and synaptic dysfunction. Little is known about the functional characteristics of the neurotransmitter receptors of the AD brain, partly because of technical difficulties of the methods employed. Using postmortem brains of humans that suffered AD, the authors were successful in trying an alternative method that has been previously used to study neurotransmitter receptors and ion channels from the human brain in great structural and functional detail. This method involves microtransplantation of cell membranes from the brain to the membrane of *Xenopus* oocytes. The foreign membrane fuses with the oocyte's own plasma membrane, providing an opportunity to study the original receptors and related molecules while they are still embedded in their natural lipid environment.

Miledi, R., Z. Dueñas, A. Martinez-Torres, C. H. Kawas, and F. Eusebi. 2004. Microtransplantation of functional receptors and channels from the Alzheimer's brain to frog oocytes. Proceedings of the National Academy of Sciences 101:1760–1763.

Countergradient Variation in *Rana sylvatica* at Microgeographic Scales

Many studies provide evidence that macrogeographic gradients in temperature associated with latitude and altitude lead to countergradient patterns of variation. A general pattern is that individuals from colder environments grow or develop faster than their conspecifics from warmer environments when placed in a common setting. The author evaluated the importance of countergradient variation in the wood frog *Rana sylvatica* at microgeographic scales. *In situ* observations at the Yale-Myers Forest in northeastern Connecticut revealed that eggs in shaded wetlands developed much slower than eggs in insolated wetlands. Thereafter, Skelly performed a common garden experiment with more than 700 embryos. He found that individuals from the darkest wetlands developed up to 12% faster than those from the lightest wetlands, which indicates that countergradient variation occurs at microgeographic scales in the wood frog.

Skelly, D. K. 2004. Microgeographic countergradient variation in the wood frog, *Rana sylvatica*. Evolution 58:160–165.

Systematics of Pygopodid Lizards and Diversification of Australian Temperate Biotas

The lizard family Pygopodidae has 38 species endemic to Australia and New Guinea. This endemicity and some fossil evidence suggest that pygopodid lizards were present in Australia before the time when Asian taxa invaded Australia. The authors used molecular (2079 bp) and morphological (86 characters) data to study the phylogenetic relationships of 32 species and two subspecific taxa of Pygopodidae. Parsimony, maximum likelihood, and Bayesian analyses were performed, with two species of diplodactyline geckos as outgroups. The molecular clock method and parametric bootstrapping were used to root the trees and test different phylogenetic hypotheses, respectively. *Aprasia*, *Delma*, *Lialis*, *Ophidiocephalus*, *Pletholax*, and *Pygopus* were recovered as well-supported clades with robustly supported relationships among them. After performing biogeographical analyses, the authors found results congruent with the idea that speciation of mesic-adapted biotas in the southeastern and southwestern corners of Australia occurred between 12 and 23 million years ago, as opposed to repeated dispersal between these two regions.

Jennings, W. B., E. R. Pianka, and S. Donnellan. 2003. Systematics of the lizard family Pygopodidae with implications for the diversification of Australian temperate biotas. Systematic Biology 52:757–780.

Norops polylepis Eggs Do Well in Pastures

How human activities affect the distribution and population dynamics of other species is a major question in ecology and conservation biology. Populations might not be self-sustaining in a habitat that is unsuitable to one or more life stages, such as the egg-stage of oviparous reptiles. Predicting that eggs would fare poorly in pastures, the author studied the effects of forest to pasture conversion on the egg stage of the Costa Rican anole *Norops polylepis*. The research was conducted in a 25-ha primary rain forest fragment that has been surrounded by pasture for 30 years. Using eggs from captive females, experiments were performed on six 25-m long transects parallel to the forest-pasture edge. Contrary to his expectation, Schlaepfer found that the eggs underwent normal development in pastures. Moreover, the incubation period was reduced in pastures, and the survival curve was significantly higher for pasture than for forest eggs.

Addendum

In the March 2004 Current Research (p. 6), we summarized a recent paper concerning the effects of UVB on amphibian embryos (Licht 2003. Bioscience 53:551–561). However, readers should also be aware of a published rebuttal to this paper by Andrew R. Blaustein and Lee B. Kats which appeared in the November 2003 (p. 1028) issue of Bioscience.

ZOO VIEW

Gerald Durrell (1925–1995) was the founder of the Jersey Wildlife Preservation Trust, now called Durrell Wildlife Conservation Trust [DWCT]. He started the Trust in 1959 on the Channel Islands off the coast of England to conserve endangered fauna, especially insular taxa. He brokered arrangements with wildlife officials and governmental agencies in those countries where endangered species occurred. His approach included management plans with both *in situ* and *ex situ* components. To accomplish this, he often arranged partnerships with other zoos, building an *in situ* component, and supporting institutions within the country of origin.

As an example of his broad approach, feral mammals and alien vegetation were eliminated before reintroduction of the Round Island boa (*Casarea dussumieri*) was attempted. Durrell was a visionary who created effective conservation enterprises, with time and money. Today, The Durrell Institute of Conservation and Ecology at the University of Kent at Canterbury UK and Durrell Wildlife Conservation Trust promote important conservation initiatives throughout the world.

At Jersey, the Gaherty Reptile Breeding Centre (now re-named the Gaherty Amphibian and Reptile Conservation Centre) is a small facility where the majority of breeding and research on taxa at risk takes place behind the scenes: ploughshare (*Geochelone yniphora*), flat-tailed (*Pyxis planicauda*) and radiated (*G. radiata*) tortoises, Round Island boa (*Casarea dussumieri*), gecko (*Phelsuma guentheri*), and skink (*Leiolopisma telfairii*), Mallorcan midwife toad (*Alytes muletensis*), Montserrat mountain chicken (*Leptodactylus fallax*), Coahuilan box turtle (*Terrapene coahuila*), San Francisco garter snake (*Thamnophis sirtalis tetrataenia*), Antiguan racer (*Alsophis antiguae*), Jamaican and Puerto Rican boas (*Epicrates subflavus, E. inornatus*), St. Lucian whiptail (*Cnemidophorus vanzoi*), spring frog (*Rana dalmatina*), and ground iguanas (*Cyclura collei*).

FIG. 1. Gerald Durrell with female Parson's chameleon. This picture was taken during the same filming trip in 1981 for 'The Ark on the Move,' probably in October, in Berenty, Madagascar. Credit: Durrell Wildlife.

Durrell published 38 books and many other articles dealing with animals (see Botting 1999. Gerald Durrell. The Authorized Biography. Carroll & Graf Publishers, Inc., New York).

Following Durrell's vision, Richard Gibson and Kevin Buley built a multi-faceted program for the flat-tailed tortoise as detailed in the following article. Gibson was Herpetology Department Head at the Trust but has since moved to the London Zoo. Buley was associated with the Department but has relocated to the Chester Zoo.

Dwight Lawson from Zoo Atlanta in Georgia USA has been a major player in the Turtle Survival Alliance (TSA). I asked him to explain the mission of this important organization and his description follows.

After forty-plus years, Peter Brazaitis retired from the Wildlife Conservation Society, headquartered at the Bronx Zoo in New York. For most of that time, Pete and I have known each other and whenever we would get together, he would regale me with humorous anecdotes. Discovering that he had published a book on his experiences at the zoo, mostly in the herpetology section, I was certain it would be an enjoyable read as he is an accomplished raconteur. When his book arrived (Villard Books, New York, 2003: ISBN 1-4000-6012-5), I eagerly picked it up and was not disappointed — how could I be when the title reads *You Belong in a Zoo. Tales from a Lifetime Spent with Cobras, Crocs, and Other Creatures* and the text reveals that his nickname was "The Bald-Headed Snake Keeper in the Bronx."

Brazaitis is one of our most respected zoo herpetologists (see Card and Murphy 2000. Lineages and histories of zoo herpetologists in the United States. Herpetol. Circ. No. 27 for details). He is a committed conservationist and his efforts to protect crocodilians, both *in situ* and *ex situ*, are a remarkable achievement. Even after retirement, Brazaitis remains active in herpetology. His professional legacy, one might ask? Pete will always be saddled with the unenviable reputation that he was the first to sex crocodilians by plunging his index finger into their cloacae, not a pretty sight for the zoo visitor!

— James B. Murphy, Section Editor

Herpetological Review, 2004, 35(2), 111.

Partners in Saving Turtles: The Turtle Survival Alliance

DWIGHT P. LAWSON
Zoo Atlanta, 800 Cherokee Avenue SE, Atlanta, Georgia 30316, USA
e-mail: dlawson@zooatlanta.org

More than 300 million years in the making, the world's turtle and tortoise fauna is now disappearing at an unprecedented rate. In addition to the usual habitat loss and degradation, massive commercialization of wild-caught animals for food and traditional medicine in the previously closed Asian markets is fuelling the removal of vast numbers of turtles and tortoises from fragile habitats in Southeast Asia and as far away as Africa and the US. To combat the accelerating scope and scale of this loss, zoological parks and aquariums, dedicated private specialists, veterinarians, researchers, and other interested individuals and organizations have forged a new and unique partnership to link and synergize their individual and institutional efforts for chelonian conservation. Established in 2001 as the Turtle Survival Alliance (TSA), the group was designated an autonomous Task Force of the IUCN/SSC Tortoise and Freshwater Turtle Specialist Group. The mission of the TSA is to develop and maintain an inclusive, broad-based global network of collections of living tortoises and freshwater turtles with the primary goal of maintaining chelonian species over the long term to provide maximum future options for the recovery of wild populations. By combining the volunteer efforts of its partners with financial support from zoological institutions such as Disney's Animal Kingdom, Cleveland Metroparks, Fort Worth, Columbus, the Wildlife Conservation Society, San Diego, Minnesota, and Atlanta, the TSA has made significant progress during its brief history.

Now more than 200 partners strong, the TSA is implementing an ambitious program of coordinating existing *ex-situ* turtle collections into viable *ex-situ* conservation management programs known as assurance colonies. Building on partnerships with government regulatory authorities in the US and abroad, the TSA has also moved otherwise doomed, illegally traded, and confiscated turtles and tortoises into this assurance colony network. The TSA currently manages more than 4000 animals, and partners have made tremendous strides in captive management and reproduction of a number of rare or enigmatic species such as the Flat-tailed Tortoise (*Pyxis planicauda*), the Sulawesi Forest Turtle (*Leucocephalon yuwonoi*), Forsten's Tortoise (*Indotestudo forsteni*), and the Yellow-headed Box Turtle (*Cuora aurocapitata*), among others.

To tie the *ex-situ* programs to efforts in the field, the TSA is expanding its capacity-building role in range countries and in the US. With financial support from organizations such as the Institute of Museum and Library Services and the American Zoo and Aquarium Association, TSA partner institutions will be conducting training programs on small population management techniques for assurance colony mangers in the US in 2004–2005. Teams of TSA partners will also be conducting regional training programs on assurance colony development and captive management aimed at animal and facilities managers and wildlife officials in Hong Kong, Singapore, and China. These programs will be assisted by a recently hired, full-time coordinator in Asia who will also inventory the resources and needs of current conservation projects and programs in southeast Asia that have potential to contribute to turtle and tortoise protection.

Showcasing the successes of its first two years, the TSA held its first annual conference in Orlando, Florida 17–19 August 2003. The event highlighted that the strength of the TSA lies in the diversity of its partners and supporting organizations. The conference featured more than 40 presentations on topics ranging from natural history observations in the field, captive management and veterinary care, to purely academic research, and was attended by more than 80 participants from 10 countries.

The breadth of TSA programs and projects points to a need for additional academic collaboration and scientific expertise in the organization, and a constant infusion of science in the process of saving turtles. For more information on TSA activities, to find out how to become a partner, or simply to help, contact Dwight Lawson (dlawson@zooatlanta.org) or Rick Hudson (rhudson@fortworthzoo.org), or visit the TSA website at www.turtlesurvival.org.

With the exception of taxonomic debate, anatomy, and Malagasy herpetofaunal reviews (Siebenrock 1903a, 1906; Vaillant and Grandidier 1910; Vuillemin 1972; Obst 1978; Bour 1979, 1981) the Malagasy Flat-tailed Tortoise has received little scientific attention. Only in the past 10–15 years have radiotelemetric and distribution studies revealed anything of the species' life history in the wild. Captive populations held for the last 15 years at Durrell Wildlife Conservation Trust's (DW) headquarters at Jersey Zoo in the Channel Islands, UK, and at its Malagasy Chelonia Field Conservation Station (CFCS) in Ampijoroa, Ankarafantsika National Park, northwestern Madagascar, have also helped to reveal much about behavior and breeding ecology.

Unfortunately, what has been learned regarding its distribution and status in the wild, together with the rapid deterioration of its forest home, gives grave cause for concern. Endemic to the Menabe region on the central western coast of Madagascar, the deciduous forests of the region are coming under increasing pressure from both international developers and logging companies, and from

FIG. 1. Adult female *Pyxis planicauda* at Jersey Zoo.

local subsistence agriculture, charcoal production, hunting, and general disturbance by people and their domestic animals. Recent unsustainable and largely illegal commercial trade in the species for the North American, European, and Far Eastern hobbyist markets has exacerbated the tortoise's precarious position. Furthermore, the sensitivity of this enigmatic tortoise in captivity and the nature of its breeding biology give little hope for large-scale conservation or commercial breeding programs. As a result, the survival of this mysterious and beautiful tortoise is in serious doubt.

Taxonomy.—Debate concerning this species' taxonomic position revolves around its inclusion in the genus *Pyxis* (Bell 1827) or separation to *Acinixys* (Siebenrock 1903b). Obst (1978, 1980) and Bour (1981) embedded *Acinixys* within *Pyxis*, designating it a subgenus. However, the characters used by Obst (1980) and Bour (1981) are juvenile traits common not only to *Acinixys* and *Pyxis*, but also to all other African testudinidids, *Homopus, Psammobates, Chersina, Kinixys,* and even some *Testudo* and *Geochelone* (Ernst and Barbour 1989). Herpetologists are divided in their use of the two genera and further examination is required to clarify the situation.

Description.—Though commonly referred to in the scientific and popular literature (even on IUCN and CITES listings) as the flat-shelled spider tortoise, *P. planicauda* is neither. Its carapace is slightly flattened along the dorsal surface but it would seem logical to refer to this animal in accordance with one of its most striking anatomical features, and its scientific name—the flattened tail. Adult females reach a maximum carapace length of 130–150 mm and weigh up to 670 g (Kuchling and Bloxam 1988; Bloxam and Hayes 1991) (Fig. 1). Males are smaller with carapace lengths rarely exceeding 130 mm, and weights up to 400 g (Bloxam and Hayes 1991). Other than their size difference females tend to be relatively wider, have an entirely flat plastron, and a very short tail. Males in contrast are narrower in shape, have more pronounced flaring of the anterior marginal scutes, a deeply concave plastron, and a long, dorsoventrally flattened tail ending with a large horny scale on the dorsal surface.

Distribution and Habitat.—*P . planicauda* inhabits dry deciduous forest on the semi-arid central western coast of Madagascar. It is restricted to fragments of forest in the Menabe region between the rivers Morondava and Tsiribihina and a small isolated population north of the latter river. The extent of its habitat is very limited and is decreasing steadily.

The substrate in this forest is a very loose, well-drained, sandy soil covered in a deep layer of leaf litter. During the wet season (late November to early April) the trees are in leaf and form a broken canopy. It rains heavily during this season, often daily and sometimes for several hours at a time. Humidity remains fairly high and temperatures can soar to 37°C or more. In the dry season (April to November) standing water is rare, rainfall is extremely unusual, and the trees lose their leaves. Temperatures drop considerably to around 27°C during the day and as low as 12°C at night (Bloxam, pers. comm.).

Behavior.—During the dry season *P. planicauda* enters a state of torpor (aestivation) and remains inactive buried deep beneath leaf litter. The relatively cool temperatures experienced deep beneath the insulating leaves and their moisture trapping properties help to ensure the survival of the tortoises during the waterless months. During rare unseasonable showers tortoises will emerge briefly to drink before returning to their retreats.

When the rains start in late November or December temperatures rise and the tortoises emerge to drink copiously. Tortoises straighten their rear legs, tilting their carapaces forward, so that rain runs down over their heads and pools in the leaves beneath them. On dry days, even during the wet season, tortoises return under the leaves and await further rain.

Tortoises are rarely seen basking in direct sunshine and body temperatures of active tortoises have been measured between 26°C in early morning and 29.5°C in mid afternoon (Kuchling and Bloxam 1988). Bloxam and Hayes (1991) found evidence that smaller, more brightly colored juveniles tended to be found in areas of open canopy and sun-dappled forest floor while darker, more uniformly colored adults were found predominately in areas of shady, closed-canopy forest.

Radio-telemetric data describing activity and movements have been collected over a number of seasons but are not yet published (Behler and Bloxam, in prep.). Even active, radio-tagged tortoises are difficult to locate and approach owing to their cryptic coloration, acute eyesight, and wary nature (Bloxam, pers. com.).

In the only study of *P. planicauda* density tortoises were estimated to occur at between 0.58 and 1.95 tortoise/1000 m^2 (Bloxam et al. 1996). These low densities suggest a largely solitary existence as tortoises would rarely encounter each other. However, this study assumed even distribution across the study area. As the habitat structure and quality is not uniform, at least temporary aggregations seem likely.

Diet.—Little data exist on wild diet. Kuchling and Bloxam (1988) observed tortoises eating the fruit of two trees (*Breonia perrieri* and *Aleanthus greveanus*), as well as leaves and shoots of various bushes. Fungus also appears to be an important part of the diet in the wild (Bloxam, pers. comm.) and would be the first available food item to tortoises emerging with the first rain after the dry season. Over 200 species of trees have been identified from the forests in which these tortoises live (Kuchling and Bloxam 1988) and it seems likely that their wild diet is extremely varied. Like many other testudinids it is likely that they are opportunistic carnivores.

Reproduction.—No data have been collected on the reproduc-

tion of *P. planicauda* in the wild. In ten years of field observations tortoises were only seen interacting on a single occasion—when two males were observed fighting (Bloxam, pers. comm.).

Hatchling tortoises have been found shortly after the start of the rainy season which suggests that eggs may hatch to coincide with the rain and subsequent availability of food. It is estimated that sexual maturity is attained in 8–12 years.

All our information on reproductive biology is derived from captive studies at the DW's Jersey Zoo headquarters and at the CFCS in northwestern Madagascar.

Captive Husbandry

Background.—DW began working with *P. planicauda* in 1988 when five (2.3; M/F) animals were collected from the Kirindy forest in western Madagascar and established at the CFCS. A additional four adults (2.2) were added in 1997 following successful management of the original animals.

Jersey Zoo obtained its first specimens (4.2) in early 1991. Three additional females were added to this group in 1997. All animals were collected from the Kirindy.

Accommodation.—*P. planicauda* at Jersey Zoo are accommodated in a purpose built, dedicated facility housing only this species. Open topped enclosures measuring 50 x 50 cm are used to individually house the males (Fig. 2). A larger 400 x 50 cm open-topped enclosure is used for communally holding the females. The 20 cm high walls of all enclosures are solid and opaque. All enclosures are constructed of fiberglass covered plywood, with sloping floors and drainage holes.

A warm water sprinkler system is used to irrigate enclosures at a height of 20 cm above the substrate. Substrate consists of a 5 cm deep layer of volcanic pebbles (Hydroleca™) covered with capillary matting to facilitate drainage. A 2–3 cm deep layer of sandy soil and deep leaf litter provides a more naturalistic substrate over the capillary matting base. One quarter of the females' enclosure is not connected to the main spray system and has a 10–12 cm deep substrate of slightly dampened sandy soil for nesting.

The enclosures are furnished with small logs under which tortoises can shelter and hardy plants such as *Ficus*, *Sansevera*, *Maranta*, *Syngonium*, and *Yucca*. The plants not only provide a natural vegetative cover but also help to maintain high humidity levels during the rainy season.

At the CFCS in Madagascar tortoises are housed simply in 150 x 250 cm enclosures divided by 22 cm high concrete blocks. Substrate is natural forest soil and leaf litter and the enclosures are shaded by small shrubs, bushes, and large teak trees (Razandrimamilafiniarivo et al. 2000).

Environmental parameters.—Replication of the extreme seasonal climatic variation is essential for the maintenance of this species in captivity. The animals at Jersey Zoo were given a six-month shift in their seasons when they were brought into captivity. The rationale for this was that the hot, wet season would then coincide with the European summer and the cooler, dry season with the winter. Although the animals are maintained in a heated, well-insulated room, obviously it is easier to provide the appropriate seasonal conditions when there is some correspondence to the local climate.

Pyxis planicauda at Jersey Zoo are kept at 27–34°C during the day and 22–26°C at night during the wet season; rainfall is simulated with a warm (20°C) water sprinkler system in operation 0.5–4 h per day. Humidity remains above 70% at all times and approaches 95% during and immediately after showers.

Fig. 2. Individual enclosures for male *Pyxis planicauda* at Jersey Zoo.

To simulate the dry season, 'rainfall' is reduced to zero as the temperatures are gradually lowered to 22–28°C in the daytime. A cooling system ensures that low night time temperatures (14–18°C) are achieved and maintained.

Photoperiod and general room lighting is provided by ZooMed Reptisun 2.0™ and varies from 14:10 h (light:dark) at the peak of the wet season to 11.5:12.5 h in the middle of the dry season. Localized hotspots/basking areas (45–55°C) are provided during the wet season. The large female enclosure is fitted with two 275W Active UVHeat™ spotlights and the male enclosures are each fitted with a 60W incandescent spotlight.

At the CFCS in Madagascar tortoises are exposed to the local seasonal climate in their outdoor enclosures which is very similar to that of their native habitat.

Diet.—At Jersey Zoo, simulated rainfall with the warm water sprinkler system is essential to rouse the animals from their dry season torpor and to ensure that they are fully rehydrated. Although water bowls are provided they have rarely been observed to use them and prefer to drink water as it pours over their head and collects in dry leaves beneath them. Daily 'rainfall' is also required to stimulate the animals to feed.

The key dietary item in the first weeks of the wet season is fungus. Oyster mushrooms are preferred but beef, shitake, and button mushrooms are also readily taken. This early season preference for fungus might reflect their wild diet where this food item would be among the first to emerge with the onset of the rains.

As the wet season progresses they begin to accept a wider variety of food items including soft and finely chopped hard fruits (particularly tomato, pear, and papaya), green vegetation (including dandelion, chicory, and pakchoi), and small quantities of animal protein in the form of a low-fat cat food.

Fruit feedings are always supplemented with Nutrobal™ multivitamin powder. Animals are fed every day during the wet season. They receive green vegetation 3–4 times per week, fruit 3–4 times per week, and animal protein 1–2 times a month. Mushrooms are provided daily for the first two weeks of the wet season and twice per week thereafter. Chopped cuttlefish bone (*Sepia* sp.) is provided *ad libitum* and sweet potato tubers are planted in the substrate, or in pots, to provide growing vegetation on which they can browse. The species is enthusiastically coprophagous which may have important implications for the inoculation of baby tortoises with beneficial gut flora.

P. planicauda at the CFCS are fed four times per week and receive a variety of leaves and fungi from the forest supplemented with *Opuntia*, banana, mango, papaya, and tomato (Razandrimamilafiniarivo et al. 2000).

Medical considerations.—Captive *P. planicauda* are prone to heavy nematode infestations which can be detected in analyzed fecal samples. This has never proven pathogenic with adult tortoises but has been implicated in the death of juveniles at the facility in Madagascar (Razandrimamilafiniarivo et al. 2000). High standards of hygiene are needed to prevent accumulation of parasites within the confines of an enclosure.

Tortoises at Jersey Zoo are occasionally wormed with Fenbendazole (Panacur™)—via stomach tube, or poured over a palatable food item—when particularly high parasites loads are apparent. Routine treatment is avoided because of the disruption to symbiotic gut flora.

Jersey Zoo has recorded one case of egg retention and binding. Oxytocin and calcium therapy was unsuccessful in this case but should normally be expected to work if the condition is diagnosed early.

P. planicauda not provided with adequate water by simulated rainfall are apt to become dehydrated, stop feeding, and lose weight quickly.

Breeding.—Observing the reproductive behavior of this timid tortoise has proven problematic at both captive facilities. At the CFCS in Madagascar a blind was built to enable observers to approach and remain in close proximity undetected. At Jersey Zoo a regular and extended staff presence in the room housing the tortoises has resulted in habituation (after 6-18 months in captivity) and specimens will now feed, drink, fight, and mate in the presence of staff.

At Jersey Zoo animals are introduced for breeding purposes shortly after the start of the wet season. Two males are paired for 15–60 minutes for intra-sexual combat in their smaller enclosures. Vigorous combat ensues involving butting and aggressive biting of fore and hind limbs. Dominant animals will often be observed to mount the other male after a period of aggressive combat.

The paired males are then separated to their individual enclosures and a female introduced. Mounting by the male is usually preceded by bouts of butting and frantic circling of the female. Receptive females remain stationary while mounting and mating occurs. Unreceptive females move continuously around the enclosure making mounting and mating impossible for the male. Confirmation of successful copulation and measurement of its duration is difficult. Once mounted on a female, males typically stretch their head and neck to its full extension and open their mouth widely. During attempted and actual copulation males make quiet, strained 'gasping' noises (the only vocalization recorded for the species). Females are left with a male for variable periods of time during the wet season (2–24 h) before being separated to their own enclosure. Repeated attempts at copulation may occur during this time. Mating is most common in the early hours of the morning but has been observed at all times of the day.

This management regime of male-male combat followed by pairing with females is repeated 3–6 times per week throughout the wet season. Successful mating has been recorded throughout the wet season but is typically more frequent during the first 2–3 months.

Pyxis planicauda at the CFCS are introduced for mating in small groups of one male and two females. This has proven successful at this facility (Razandrimamilafiniarivo et al., 2000), but trials at Jersey Zoo with this group structure resulted in males being distracted while mounted on one female by the presence of a second (pers. obs.). Similarly, a group structure of two males and one female also leads to interruption with the mounted male distracted by the competing male or the competitor dislodging the mounted male from the female (pers. obs.; Razandrimamilafiniarivo et al. 2000).

Egg laying usually begins 30+ days after mating is first observed (Razandrimamilafiniarivo et al. 2000). Females usually begin nesting after sunset and will continue into the early hours of the following morning. The nest is dug in sandy soil (5–6 cm deep) and a single large egg deposited. Females may lay up to three clutches of one egg in a season at intervals of 3–6 weeks. Data for 38 eggs are as follows (mean, range): mass = 19.7 g (15.4–22.2 g); length = 38.0 mm (34.1–41.6 mm); width = 29.7 mm (27.2–31.7 mm).

Eggs are laid in the second half of the wet season but do not hatch until the beginning of the following wet season. There appears, therefore, to be suspended development of eggs (diapause) such that hatchlings emerge when food is abundant rather than in the middle of the dry season. Consequently, incubation periods vary considerably. Eggs laid three months apart in one wet season may hatch within days of one other at the start of the following season.

Razandrimamilafiniarivo et al. (2000) have recorded incubation periods between 257 and 343 days (mean = 291 days, N = 20) under natural incubation conditions. Artificially incubated eggs hatched at Jersey Zoo have incubated for >213 days, 262 days, and 306 days (Table 1). All eggs laid at Jersey Zoo are subjected to the environmental conditions experienced by the adult tortoises, thereby mimicking natural conditions. After nesting, eggs are excavated, weighed, and measured before being half buried in a small bowl of dry vermiculite. This bowl is then placed in a large (200 x 200 x 130 mm) opaque plastic box (with a lid) half-filled with dampened vermiculite (1:1 water:vermiculite, by weight). The box is kept in the *P. planicauda* room where it is subjected to the daily and seasonal temperature fluctuations. The box is opened twice per week to permit air exchange (this also has the gradual effect of allowing the dampened vermiculite to dry, and the humidity in the box to drop). Towards the end of the dry season the boxes are

FIG. 3. *Pyxis planicauda* hatching.

moved to an incubator where they are maintained at 30–31°C. Humidity in the box is gradually increased again by adding water to the vermiculite in the box.

At Jersey Zoo females have been consistent and regular egg layers. On average, 2–3 eggs are laid by each female each season. Despite observations of confirmed copulation prior to egg laying the instances of fertility have been very low. It is hypothesized that this may be due to the artificially imposed shift of seasonal activity by six months in order to correspond with our own European summer and winter seasons. If this is the case we expect the rate of fertility to improve over coming years as their behavioral and physiological cycles become aligned.

Hatchling *P. planicauda* may stay inside the shell for up to one week after pipping (Fig. 3). During this time they are prone to dehydration and are lightly sprayed with warm water. Hatchlings have a plastral fold so severe that it extends into the carapace giving them a crumpled appearance on emergence. Full straightening of the plastron and carapace can take weeks and a small crease is often visible in the centre of each bridge many months after hatching.

Juvenile *P. planicauda* have proven highly sensitive to nematode infestation at the CFCS. Changes in tortoise management including improved hygiene, regular substrate changes, and drug therapy are alleviating this problem (Razandrimamilafiniarivo et al., 2000).

Rearing of juveniles at Jersey Zoo has also proved problematic. The first hatchling died at 18 months of age after more than 6 months of poor appetite and failure to gain weight. It is hypothesized that deviation from the strict seasonal regime was to blame (the wet season was artificially extended to try to encourage feeding and weight gain). Two subsequent hatchlings are now given the same seasonal regime as the adult animals.

Only four *Pyxis planicauda* are reported to have been bred outside Madagascar in zoos. Three of these hatched at Jersey Zoo (Table 1) and one at Knoxville Zoo in the USA in May 2002. These four animals represent the total breeding success with *P. planicauda* at three internationally renowned zoos (including Bronx Zoo) over a collective period of more than 25 years. There are recent reports of successful hatching of eggs from recently imported (gravid) *P. planicauda* in the private sector in the USA and Europe but regular, repeatable reproduction of established long-term captive animals has yet to be achieved.

CONSERVATION

Pyxis planicauda is in real danger of extinction. It is listed by the World Conservation Union as Endangered (IUCN 2000). With its limited distribution and specialized habits it is vulnerable to forest disturbance, degradation, fragmentation, and destruction. All of these are occurring in the Menabe region. Oil prospecting in the early 1990s opened up the forest to local people and their cattle resulting in slash and burn agriculture, burning for cattle pasture, felling of firewood, and the spread of feral pigs which are suspected predators of eggs and young (Bloxam et al. 1993; Bloxam and Hayes 1991). Legal logging continues and there have been proposals for large agricultural developments including sugar cane, and more recently chicken farming and sisal plantations (Kuchling and Bloxam 1988; Bloxam, pers. comm.).

Pyxis planicauda is now listed by CITES (Convention on International Trade in Endangered Species) on Appendix I which prohibits any trade in wild specimens. This listing was made in response to an escalating and apparently unregulated international trade in illegal and legal specimens for the hobbyist trade in Europe, the USA, and the Far East during the late 1990s. Animals arriving in Europe and the USA alone far exceeded export quotas set by CITES and the Malagasy authorities. This poorly controlled and ill-advised trade has placed several thousand of these sensitive and shy tortoises in the hands of not just the experienced, dedicated amateur herpetoculturist, but also the unprepared pet keeper. Many of these tortoises will die prematurely and breeding among those that survive will be exceptional.

There is anecdotal evidence that an isolated population of *P. planicauda* towards the south of its range has been extirpated through trade in the past five years (Durbin and Lewis, pers. comm.).

The low density at which these tortoises appear to occur in the wild and their reproductive biology—with low fecundity and slow maturation—suggest that any level of commercial collection from the wild is likely to be unsustainable. The nature of the species' reproductive biology similarly hinders attempts to establish captive conservation populations and casts serious doubt upon existing and proposed self-sustaining commercial operations to supply the interna-

tional pet trade.

If trends in collection, habitat destruction, forest fragmentation, and human encroachment persist, the long-term future of *P. planicauda* in the wild looks very bleak. The deciduous forests of the Menabe region are of enormous ecological importance and are home to a wide variety of endemic plants and animals and to many internationally threatened species.

It is not only *P. planicauda* whose survival is in question but also that of the Narrow-striped Mongoose (*Mungotictus decemlineata*), the Giant Jumping-Rat (*Hypogeomys antimena*), Berthe's Mouse Lemur (*Microcebus berthae*), a plethora of reptile and amphibian species, and possibly other endemic species not yet described.

International awareness of the plight of *P. planicauda* can provide valuable support for future conservation initiatives in the Menabe region. However, it will require many years of hard work by determined conservationists and herpetologists, the implementation of appropriate legislation, and a lot of luck to ensure that the forests of Menabe remain the home of kapidolo, the 'ghost turtle,' for centuries to come.

Acknowledgments.—Our greatest thanks are due to Quentin Bloxam for sharing with us his many years of field experience with the species. John Behler, Joanna Durbin, Richard Lewis, Olivier Razandrimamilafiniarivo, Don Reid, and Bern Tryon have all provided useful thoughts and insight over the past years and have therefore contributed to the content of this paper. The Durrell Wildlife Conservation Trust supports both the captive breeding programs in Madagascar and Jersey Zoo, and field excursions past and present.

Protecting One's Research Turf: Right of Possession or Self-styled Imperialism?

CARLOS D. CAMP
Department of Biology, Piedmont College
PO Box 10, Demorest, Georgia 30535, USA
e-mail: ccamp@piedmont.edu

I was sitting in my graduate-student cubicle at the Savannah River Ecology Laboratory back in 1981 when my major professor, Whit Gibbons, unexpectedly appeared in the doorway. He was rhythmically slapping one hand into the other, a tell-tale signal that something was up. "It's mighty early in your career to be making enemies," he said. Earlier in the week I had phoned a leading authority, whom I shall refer to as Dr. Thibodeaux, about a research idea that I was pondering as a possible dissertation topic. We had what I thought was a pleasant, helpful conversation, but

Dr. Thibodeaux promptly called Whit and told him to stop me from pursuing the topic. He claimed that this was his idea, and he intended to work on it sometime in the indefinable future. Whit expressed his support for whatever I wanted to do, but I ended up changing dissertation topics. Little did I realize, however, that I would run into the same situation with another respected authority from a different field. Submission of my dissertation work for publication (Camp 1988) prompted a letter from Dr. Erhöhung (again, a pseudonym), who happened to serve as a reviewer for the journal. Dr. Erhöhung essentially told me to cease and desist from all work in this area as it competed with part of a broader study that he was conducting. He noted that he had earlier published a statement of intent concerning his study and, therefore, no one else had any right working on it. More recently, this same researcher has used his influence to get a major, publicly funded museum to deny me access to specimens for the same stated reason. Considering these personal experiences, I have no doubt that similarly minded researchers may use their influence to prevent "threatening" papers from getting published. I would hope, however, that this ploy succeeds only rarely.

I suspect that few researchers actually have the clout to prevent others from working in "their area." More commonly, perceived encroachment simply generates hard feelings, with the unfortunate consequence of preventing meaningful collaboration. On the other side of the same coin, I know researchers who avoid working on certain topics or even reviewing related manuscripts for fear of stepping on someone's toes. I do not know if this mindset of first-come, first-research is unique to herpetology, but other scientific disciplines seem rife with competitive research, as rival labs race for the accolades of scientific discovery.

Although herpetology may seem enviable with its ordered, friendly, even chivalrous approach to doling out research areas, the result is to stymie scientific advancement. Platt (1964) argued that science successfully proceeds by testing competing, alternative hypotheses. The effective stillbirth of such hypotheses through the exclusion of other minds translates into a *status quo* that retreads the same old stale ideas and stifles intellectual headway. I believe that this attitude has, at least in part, contributed to a "lack of novel hypotheses" (Tilley and Bernardo 1993) in certain areas of herpetology. Moreover, the confirmation of conclusions through the replication of results is an important, albeit often overlooked cog in the engine of scientific progress.

It is particularly disheartening when established researchers, whose careers have already been made, expect new, budding scientists (i.e., graduate students) to tug their forelocks in deference and meekly shuffle off to find something else to work on. This sends, if not exactly a stake through the heart of science, certainly a thorn into its flesh. After all, it is not the old dogs that create new, revolutionary ideas, but it is those who are "almost always...either very young or very new to the field....who, being little committed by prior practice to the traditional rules of normal science, are particularly likely to see that those rules no longer define a playable game and to conceive another set that can replace them" (Kuhn 1970).

We are all human, and none of us likes the thought of being scooped. I fully understand the annoyance resulting from a discussion with a young colleague that inadvertently creates a competitor. Even so, competition sharpens us as scientists, and the fear of it does not legitimize claims of ownership. Planting one's flag, so to speak, in certain research topics or taxonomic groups is nothing short of intellectual imperialism. Protecting research turf may contribute to legacy-construction, but science is driven by ideas, not legacies. Science in general, and herpetology in particular, benefits by putting personal claims aside. My advice to those who wish to avoid being scooped is to simply work faster. To those considering research projects in "pre-owned" areas, go ahead. Rather than deferring to the authorities, send them reprints.

Acknowledgments.—Thanks to Ben Cash, Whit Gibbons, John Jensen, and Associate Editor Brian Bowen for their helpful comments.

Dowling et al. (1996) used allozyme data from four protein loci to infer higher level snake phylogeny. Their conclusions were based on a single tree inferred using UPGMA clustering. Buckley et al. (2000) reanalyzed the allozyme data of Dowling et al. (1996), discovering numerous identical distance values between pairs of taxa and therefore the existence of numerous equivalent UPGMA trees. Based on more thorough tree searches using UPGMA clustering, minimum evolution, and parsimony analysis, they concluded that the data in question were highly ambiguous concerning the higher level phylogeny of snakes, and that the high degree of resolution in the tree of Dowling et al. (1996) was an artifact produced by selecting one out of many equivalent trees.

Highton et al. (2002) responded by questioning three of the practices used by Buckley et al. (2000) to reach their (our)

conclusions: 1) our exclusion of OTUs with allelic complements (and therefore genetic distances) identical to those of other OTUs in the distance matrix, 2) our use of a single taxon input order rather than multiple randomized input orders of taxa, and 3) our use of the strict consensus method rather than the majority-rule consensus method. The overall suggestion was that, when these three supposed problems are corrected, the data in question yield a high degree of phylogenetic resolution. That conclusion is unfounded, as we here demonstrate by addressing the three criticisms.

It should be noted that although Highton et al. (2002) stated that their original study was aimed primarily at lower level relationships, Dowling et al. (1996) nevertheless presented a tree that had considerable resolution regarding deep branches and called attention to the existence of 18 major groups and their interrelationships (see their Fig. 6). Furthermore, the somewhat less resolved tree defended by Highton et al. (2002) still exhibits considerable deep resolution. Thus, the issue remains whether the data of Dowling et al. (1996) support the level of resolution in the tree presented by Highton et al. (2002) as opposed to the much lower levels of resolution in the results of Buckley et al. (2000).

1. Exclusion of Identical Taxa

One of the reasons that Highton et al. (2002) obtained greater resolution than we did for the same data was that they retained taxa with identical alleles at all four loci that they surveyed. Buckley et al. (2000) removed identical taxa prior to analysis because such taxa provide no additional information about the structure of the tree (i.e., beyond the fact that they will always cluster with the taxa to which they are identical). According to Highton et al. (2002:720), "Actually, adding or deleting identical taxa may affect tree topology. If identical OTUs are removed from a study, the remaining OTUs may join more basal branches in a different order." Although they are correct in stating that removing identical taxa can affect tree topology, at least for some methods (see below), and although we overlooked the fact that this property holds for UPGMA clustering, we maintain that the sensitivity of that method to the presence or absence of identical taxa is an undesirable property. The resolution resulting from it in the trees of Dowling et al. (1996) and Highton et al. (2002) is therefore unwarranted.

Consider the example of *Amphiesma stolata*, *Clonophis kirtlandi* and various taxa with identical alleles at all four loci, *Sinonatrix annularis*, *Regina rigida*, and *R. septemvittata*. In our UPGMA consensus tree (Buckley et al. 2000:Fig. 1), based on an analysis that excluded the taxa identical to *Clonophis*, each of these taxa forms a separate branch of a large polytomy made up of 73 branches, three nodes above the root of the tree. This situation reflects the fact that several of the species in question exhibit distances of 0.5000 or (in one case) 0.7500 to one another, which are equal to or greater than distances between these species and other species making up other branches of the polytomy, in particular, those making up a group composed of species of *Rhabdophis* and *Xenochrophis*. In contrast, in the majority rule consensus tree of Highton et al. (2002:Fig. 1), the species of *Amphiesma*, *Clonophis* and identical taxa, *Sinonatrix*, and the two species of *Regina* form a resolved group, and moreover, that group is resolved as being most closely related to the group composed of *Rhabdophis* and *Xenochrophis* species.

These discrepancies result from the inclusion versus exclusion of identical taxa in combination with the properties of UPGMA clustering. UPGMA is an average linkage clustering method (Sneath and Sokal 1973). It operates by iteratively forming groups made up of pairs of taxa (OTUs), or of previously formed groups, based on the average distances between their member OTUs. As the name indicates, UPGMA uses an unweighted averaging procedure. This means that when OTUs or groups of OTUs are united to form an initial or larger group, the average distance between this new group and all other OTUs or groups (which is needed to determine which group to unite in the next iteration of the procedure) is calculated by taking the arithmetic mean (average) of all of the relevant pairwise distances between the individual OTUs as present in the original (unclustered) matrix. This "unweighted" averaging procedure has the effect of weighting all comparisons equally and can be contrasted with the weighted averaging procedure used in a related method known as WPGMA. In weighted averaging, the average distance between a group and all other OTUs or groups is calculated by taking the average of the pairwise distances, not between individual OTUs in the original matrix, but between the two groups of OTUs in the matrix used in the previous iteration of the procedure. For example, suppose a previously formed group composed of *Clonophis kirtlandi* and *Sinonatrix annularis* is united to form a larger group with *Regina septemvittata*. With unweighted averaging, the distance from the group composed of these three species to *Regina rigida* will be calculated as the average of the distances between *C. kirtlandi* and *R. rigida*, *S. annularis* and *R. rigida*, and *R. septemvittata* and *R. rigida* = (0.5000 + 0.5000 + 0.2500)/3 = 0.4166. In contrast, with weighted averaging, the distance from the group of three species to *R. rigida* will be calculated as the average of the distance between the group *C. kirtlandi* + *S. annularis* and *R. rigida* (calculated in the previous iteration of the procedure) and that between *R. septemvittata* and *R. rigida* = (0.5000 + 0.2500)/2 = 0.3750.

Because of the properties of unweighted averaging, it should be clear that the inclusion of identical taxa can indeed affect the results of UPGMA clustering (but should not affect those of WPGMA clustering). Thus, using the same example, if taxa with identical alleles to those found in *Clonophis kirtlandi* are included in the analysis, then these taxa will always cluster with *Clonophis* before either they or *Clonophis* clusters with other taxa, and therefore, the distance between any OTU or cluster and one containing *Clonophis* and these identical taxa will be affected by the inclusion (and number) of the identical taxa. Specifically, when taxa identical to *Clonophis* are excluded, *Amphiesma stolata* clusters with *Rhabdophis* and *Xenochrophis* rather than with *Clonophis*, *Sinonatrix* and *Regina* in some of the identical UPGMA trees, reflecting the fact that *A. stolata* exhibits distances to the former taxa (0.5000) that are as small or smaller than those that it exhibits to some of the latter taxa (0.5000–0.7500). However, if even one taxon identical to *Clonophis* is included, then the average distance from *Amphiesma* to any group containing *Clonophis* and identical taxa is decreased, and *Amphiesma* always clusters with one or more of *Clonophis*, *Sinonatrix*, and *Regina* before it clusters with *Rhabdophis* and *Xenochrophis*, despite the fact that some of the distances between *Amphiesma* and the former taxa (0.5000–0.7500) are as large or larger than those that it exhibits to the latter taxa

(0.5000). Such resolution is not warranted by the data, and this situation suggests that either the identical taxa should be excluded or, if they are to be included, that WPGMA rather than UPGMA clustering should be used.

2. Taxon Input Order

Highton et al. (2002) are correct in their assertion that randomization of the input order of taxa can be used to break ties. However, they are incorrect in stating that "Buckley et al. (2000) reached their conclusions [i.e., about lack of resolution] because they used only strict consensus trees and did not randomize the order of their input taxa" (p. 270). In fact, the procedure of randomizing taxon input order is functionally equivalent to the systematic (NTSYS) and random (PAUP) tie-breaking procedures used by Buckley et al. (2000). All of these methods cause the clustering procedure to follow different pathways in the case of tied-values, and consequently, they produce different, but equivalent, trees. The main differences are that all possible pathways are taken in the case of systematic tie-breaking, while (usually) different random pathways are taken in the case of random tie-breaking and randomizing taxon input order. Therefore, the greater resolution in the consensus tree of Highton et al. (2002:Fig. 1) relative to that of Buckley et al. (2000:Fig. 2) results from the difference in consensus methods (see below) and the fact that Highton et al. (2002) examined only 50 of the many equivalent trees, compared to the 9999 (systematic tie-breaking) and 1000 (random tie-breaking) equivalent trees examined by Buckley et al. (2000).

It should be noted that Highton et al.'s discussion of the relationships among *Carphophis*, *Diadophis*, and *Farancia*, which they used to argue that we should have used different random input orders of taxa, is confused. They correctly pointed out that the UPGMA tree of Dowling et al. (1996:Fig. 3) and the strict consensus of the 9999 UPGMA trees of Buckley et al. (2000:Fig. 2) both have the relationships ((*Carphophis*, (*Diadophis*, *Farancia*)), and this is also true for the majority rule consensus of the 50 UPGMA trees of Highton et al. (2002:Fig. 1). However, they incorrectly stated that "In [Buckley et al.'s] Fig. 3, their 9999 trees all had a different topology ((*Carphophis*, *Diadophis*), *Farancia*) indicating the input order had been reversed" (Highton et al. 2002:271). On the contrary, Fig. 3 of Buckley et al. is not the consensus of 9999 UPGMA trees but of six minimum evolution (ME) trees, with branches less than 0.0646 (the smallest observed value) collapsed. For our ME analysis, we used the same input order of taxa as for our UPGMA analyses. Therefore, the difference between our ME consensus tree and the various UPGMA consensus trees presumably results from the different method used for that analysis.

In contrast with UPGMA, the ME method does not assume (approximate) evolutionary rate equality among lineages. This property is important in the case of the three taxa in question, because although *Carphophis* exhibits a greater distance to *Diadophis* (0.3571) and *Farancia* (0.5991) than those taxa do to each other (0.3318), the *Carphophis* and *Diadophis* lineages appear to be evolving rapidly for the set of loci sampled, relative to the *Farancia* lineage. Assuming that these three taxa form a monophyletic group (as suggested by both the UGPMA and ME but not the parsimony analyses of Buckley et al. 2000), relative rate tests using *Calamaria gervasii* and *Rhamphiophis oxyrhynchus* (taxa that share the most alleles with *Carphophis*, *Diadophis*, and *Farancia*) as outgroups, reveals substantially greater distances to *Carphophis* and *Diadophis* (D = 0.8664 – 0.9286) than to *Farancia* (D = 0.5000–0.5991). Consequently, even though *Diadophis* is more similar to *Farancia* than to *Carphophis* (for the loci in question), as indicated by the results of the UPGMA analysis, it may share a more recent common ancestor with *Carphopis* than with *Farancia*, as indicated by the results of the ME analysis.

The pattern of shared alleles supports this interpretation. At the only locus (*Acp*) for which *Diadophis* and *Farancia* share an allele (24) not found in *Carphophis*, the allele in *Carphophis* (31) is unique to that taxon (among all snakes examined) and is therefore potentially autapomorphic. In other words, the allele shared by *Diadophis* and *Farancia* may be ancestral for all three taxa, and consequently, the fact that it is shared by *Diadophis* and *Farancia* does not support a relationship between those taxa to the exclusion of *Carphophis*. In contrast, *Carphophis* and *Diadophis* share an allele (07) at the *Mdh* locus that appears to be derived relative to the allele (06) present in *Farancia* (based on presence of allele 06 in other snake species), suggesting that *Carphophis* and *Diadophis* share a common ancestor not shared by *Farancia*.

Highton et al. (p. 271) reached their erroneous conclusion about taxon input order because they believed that "the *I*-value between the pair *Carphophis* and *Diadophis* is the same as that between *Diadophis* and *Farancia*" and "the tie was no longer present [in the majority rule consensus tree of Highton et al.] because [they] included two species of *Farancia*." On the contrary, the *I* value for the *Carphophis*-*Diadophis* comparison ($I = 0.6429$; D = 0.3571) is not the same as that for the *Diadophis* -*Farancia* comparison ($I = 0.6682$; D = 0.3318), reflecting the fact that the allele shared by *Carphophis* and *Diadophis* at the *Pgm* locus (08) is polymorphic in both taxa, while that shared by *Diadophis* and *Farancia* (also 08) is polymorphic in *Diadophis* but not in *Farancia* (both pairs of taxa share all their alleles at two of the other three loci and none at the third). Thus, the clustering of *Diadophis* with *Farancia* in the various UPGMA analyses has nothing to do with including two species of *Farancia*. Because the distance between those two taxa is smaller (D = 0.3318) than the distance between *Carphophis* and *Diadophis* (D = 0.3571) and that between *Carphophis* and *Farancia* (D = 0.5991), *Diadophis* and *Farancia* cluster together in all the various UPGMA analyses—both those excluding (Buckley et al. 2000:Fig. 2) and those including (Highton et al. 2002:Fig. 1) the second species of *Farancia*. (The same is true for the Cavalli-Sforza and Edwards chord distances used by Highton et al., which are 0.0383, 0.0444, and 0.0679, respectively.)

3. Consensus Methods

The suggestion by Highton et al. (2002) that we overlooked the phylogenetic signal present in the data of Dowling et al. (1996) by using the strict consensus method rather than the majority-rule consensus method highlights the general problem of deciding which groups are to be considered supported by the results of a phylogenetic analysis. Consensus methods, of which several have been proposed (reviewed by Swofford 1991; Nixon and Carpenter 1996), bear on this question in that they are commonly used to assess agreement among the members of a set of equivalent trees. The strict consensus method (Schuh and Polhemus 1981) used by

Buckley et al. (2000) retains only those groups that appear on all trees in the set. In contrast, the majority-rule consensus method (Margush and McMorris 1981) advocated by Highton et al. (2002) retains all groups that are present in some arbitrarily specified proportion of the trees greater than or equal to 50%. Other less-than-strict methods (e.g., reduced consensus, Adams consensus) also seek to retain more resolution, but this increased resolution is accomplished at the expense of ignoring contradictory data (Kearney 2002; Nixon and Carpenter 1996).

Choice of a consensus method reflects the stringency of the standard of group support adopted. Within this framework, various standards of group support form a continuum ranging from least rigorous to most rigorous as follows: any character support at all → present on any of the optimal trees → present on a majority (>50%) of the optimal trees (the criterion adopted by Highton et al. 2002) → present on various fractions of the optimal trees above 50% → present on all (100%) of the optimal trees (the criterion adopted by Buckley et al. 2000) → present on a majority (> 50%) of the optimal trees resulting from bootstrap/jackknife analysis (this criterion will not always be more stringent than the preceding one because it is based on a qualitatively different property) → present on various fractions above 50% of the trees resulting from bootstrap/jackknife analysis (commonly used fractions are 70%, 90%, and 95%).

In this context, Highton et al. (2002) advocated a consensus method (50% majority-rule) that resides near the permissive end of the spectrum, whereas Buckley et al. (2000) used one (strict or 100% majority rule) that corresponds with a more stringent criterion. As a result, Highton et al.'s (2002) consensus tree contains groups that are contradicted by some of their equivalent trees, whereas Buckley et al.'s (2000) consensus tree contains only those groups that are not contradicted by any of their equivalent trees. Although authors are free to adopt as permissive or stringent a criterion as they see fit, the recent trend in phylogenetics has been to use much more stringent criteria than the one adopted by Highton et al. (2002). Thus, the strict consensus method is the most commonly used consensus method for representing agreement among equivalent optimal trees resulting from a single phylogenetic analysis (Nixon and Carpenter 1996; Swofford 1991), and many recent authors demand even more stringent criteria for considering a group to be adequately supported, such as presence in 70% or even 95% of the optimal trees obtained using bootstrap or jackknife resampling methods.

We performed bootstrap analyses, each with 100 replicates, using the phylogenetic software packages PAUP* version 4.0b10 (Swofford 2002), for UPGMA and parsimony analyses, and FastME (Desper and Gascuel 2002), for minimum evolution analyses, to assess levels of support provided by the allozyme data for various groups of taxa. Following the program default, we considered presence of a group in 50% of the bootstrap replicates to be the minimum level of acceptable support (given that a group present in less than 50% of the replicates can be contradicted in more replicates than it is supported). The original published tree of Dowling et al. (1996) has 122 groups (nodes), or 103 excluding those composed of taxa with identical character states; the majority rule consensus tree of Highton et al. (2002) has 105 groups, or 86 excluding those composed of identical taxa. By comparison, bootstrap analysis using UPGMA yielded only 18 and 8 groups (total and excluding those composed entirely of identical taxa) supported in greater than 50% of the replicates; bootstrap analysis using minimum-evolution yielded only 40 and 19 groups; and bootstrap analysis using parsimony analysis yielded 0 groups.

In sum, the majority-rule consensus tree presented by Highton et al. (2002) corresponds with a relatively permissive criterion of support (presence in > 50% of the equivalent trees) in that it retains groups that are contradicted by some of the equivalent trees. Under more stringent criteria that are widely adopted by contemporary workers (presence in all of the optimal trees; presence in greater than 50% of the trees resulting from bootstrap analysis), considerably less resolution is obtained. Moreover, the UPGMA clustering method used by Highton et al. (2002) carries an unrealistic assumption of evolutionary rate constancy among lineages (de Queiroz and Good 1997, and references therein), and at least some alternative methods yield even less resolution and/or contradictory groupings (e.g., the relationships among *Carphophis*, *Diadophis*, and *Farancia*) for the allozyme data in question (Buckley et al. 2000).

Conclusion.—Rather than contradicting the conclusions of Buckley et al. (2000), the results presented by Highton et al. (2002) reinforce those conclusions. Although Highton et al. (2002) are correct in stating that the removal of identical taxa can affect the order of clustering by UPGMA, any increased resolution that results from including identical taxa is not warranted by the data in that it is an artifact of sampling and the averaging method used by UPGMA. Highton et al. (2002) are incorrect in stating that if we were interested in the effects of ties on the topology of UPGMA trees based on the snake allozyme data, we should have randomly reordered the input of taxa. In fact, the tie-breaking procedures that we used are equivalent to varying the input order of taxa, and we performed much more thorough tie-breaking analyses than did Highton et al. (2002) (our analyses effectively used 20 to ~200 times the number of different input orders used by them). Finally, Highton et al. (2002) used a very permissive criterion (majority-rule consensus) for deciding which nodes to consider resolved. A more conservative and widely used criterion (strict consensus) results in far less resolution (particularly when more thorough tie-breaking analyses are performed), and a standard method for assessing nodal support indicates that most of those nodes are very weakly supported.

For these reasons, our conclusions remain unchanged. The snake allozyme data of Dowling et al. (1996) are highly ambiguous concerning the higher level phylogeny of snakes, though they may be informative at lower hierarchical levels. The high degree of resolution in the original tree of Dowling et al. (1996:Figs. 1–6) is an analytical artifact that results from failure to consider alternative trees implied by numerous tied distance values. In addition, the new tree presented by Highton et al. (2002:Fig. 1), though less resolved than the one presented by Dowling et al. (1996), still contains more resolution than is warranted by the data. Many of the groups in that tree result from 1) retaining identical taxa in conjunction with use of a tree reconstruction method (UPGMA) that is sensitive to the numbers of identical taxa sampled, 2) performing a less than thorough tie-breaking analysis, and 3) using a permissive consensus method (majority-rule) that allows contradicted groups to be retained in the summary tree.

Reproductive Arrest in *Sceloporus mucronatus* (Lacertilia:Phrynosomatidae) Correlated with "El Niño Southern Oscillation"

FELIPE RODRÍGUEZ-ROMERO

and

FAUSTO R. MÉNDEZ-DE LA CRUZ

Departamento de Zoología, Instituto de Biología
Universidad Nacional Autónoma de México
Ciudad Universitaria, Circuito exterior A. P. 70-153
C. P. 04510, México, D.F., México
e-mail: feliper@ibiologia.unam.mx

The most common reproductive patterns in *Sceloporus* lizards that inhabit temperate and high mountain zones in central Mexico are viviparity and fall reproduction (Guillette and Méndez de la Cruz 1993; Méndez-de la Cruz et al. 1998). Indeed, all species of the *torquatus* group (*S. jarrovii, S. cyanogenys, S. mucronatus, S. torquatus, S. poinsetti, S. dugesi,* and *S. serrifer*) that have been studied exhibit fall ovulation and spring parturition following 5 to 7 months of gestation (Méndez-de la Cruz et al. 1998). Previous studies of these species have shown that one litter per year is characteristic, but that parturition might be delayed by less than one month (Guillette and Méndez-de la Cruz 1993; Méndez-de la Cruz et al. 1998).

Clutch size is an adaptation to abiotic and biotic environmental factors and is an important reproductive trait of lizards (Fitch 1985). In general, lizards produce at least one clutch per year, but clutch size might vary within a population from year to year (Abell 1999; De Marco 1989). Desert lizards might reduce egg production in response to low precipitation as described for several species of *Uma* (Mayhew 1965; 1966a; 1966b), *Urosaurus ornatus* (Martin 1977), and *Uta stansburiana* (Worthington 1982). Reproduction was totally curtailed in *Cnemidophorus tigris* (Pianka 1970) and *Sauromalus obesus* (Nagy 1973) when extremely dry conditions reduced food resources.

We suggest that the reported reproductive failure in *C. tigris* and *S. obesus* was associated with the climate phenomenon called "El Niño Southern Oscillation" (ENSO). This event is the result of unusual periodically occurring sea surface temperature conditions in the eastern tropical Pacific Ocean that have global climatic effects (Trenberth 1997). During the last 50 years, 12 ENSO events have been recorded; the most severe event in Mexico occurred during 1997–1998 (Magaña and Morales 1999).

Our study of the viviparous lizard *Sceloporus mucronatus*, which inhabits the high altitude zone of central Mexico, was carried out during three consecutive years (1996–1998) in the same outcrop. The study area was located near Zoquiapan, Estado de México (19°20'04"N, 98°42'49"W). Twenty-eight females were randomly collected from crevices in rocks by hand, noose, or by using a wire to force a lizard from its refuge. Lizards were captured in May and June, prior to parturition. Lizards were housed for approximately one month in terraria with food and water *ad libitum* until the beginning of parturition, which is marked by sinuous abdominal contractions as previously described by Cuellar (1984). Data obtained from each female were snout–vent length (SVL to 1 mm) and total body mass (TBM) plus litter weight (to 0.1 g). After parturition, litter size and litter mass per female were determined.

For years with offspring production, we statistically compared litter size (LS), litter mass (LM), individual litter mass (ILM), female SVL, and female mass by year using t-tests. ANCOVA was used to compare female TBM from all three years, using SVL as a covariate, and year as a factor. ANCOVA was also used to compare the litter size of this population with different populations described in a previous study (Méndez-de la Cruz et al. 1993), using SVL as a covariate and study as a factor. Data were analyzed using SYSTAT. A significance criterion of $p \leq 0.05$ was used for all statistical analyses. Means ± 1 SE are reported.

The twelve adult females collected during 1996 and 1997 were all gravid, and the t-test for LS, LM, ILM, and female SVL and TBM showed no significant difference between years ($t_{LT} = 0.93$, $P = 0.19$; $t_{LM} = 0.70$, $P = 0.25$; $t_{ILM} = 0.044$, $P = 0.33$; $t_{SVL} = 1.23$, $P = 0.13$; $t_{TBM} = 1.86$, $P = 0.07$). However, during 1998, none of the sixteen females collected was gravid, and no neonates were seen in the field. Females collected in 1998 were significantly different from the 1996–1997 females. The ANCOVA between body mass and year using SVL as a covariate showed significant differences between 1998 and 1996–1997, but not within 1996–1997 ($F_{1,2} = 19.09$; $P = 0.0001$). SVL and TBM for reproductive fe-

males were 83.66 ± 0.65 mm and 26.48 ± 0.51 g, respectively. The average SVL and TBM for non-reproductive females were 78.56 ± 0.28 mm and 16.5 ± 0.19 g.

From August 1997 to June 1998 the National Center for Environmental Prediction (NCEP) documented the development and persistence of strong warm-episode conditions on the west coast of North America (http://www.ncdc.noaa.gov). In México, the ENSO decreased rainfall from Summer 1997 to Winter 1998 (Magaña and Morales 1999). Additionally, large fires and more dust than usual were evident in the study area, particularly during the first five months of 1998 (pers. obs.). These climate changes affected the structure and dynamics of many ecosystems (Delgadillo-Macias et al. 1999; Holmgren et al. 2001).

Previous studies showed a strong influence of food availability on reproductive traits in different reptiles (Ferguson and Talent 1993; Ford and Seigel 1994; Martin 1973, 1977; Seigel and Ford 2001; Shine and Madsen 1997). However, the only study of the negative impact on food availability during an ENSO was conducted on *Amblyrhynchus cristatus* (Wikelski and Thom 2000). We suggest that reproductive disruptions found in previous studies such as decreased reproductive activity (Abell 1999; De Marco 1989; Martin 1977; Mayhew 1965, 1966a, 1966b; Worthington 1982) or complete reproductive arrest (Nagy 1973; Pianka 1970), can be attributed to ENSO events, as ENSO periods correspond to field work or collecting dates in those studies.

Differences in female SVL and TBM observed during 1998 vs. 1996–1997 in *S. mucronatus* are correlated with the unusually dry environmental conditions brought on by the ENSO event during last five months of 1997, when females became vitellogenic and gravid and during the first five months of 1998 when gestation continues and parturition occurs. We suggest that the ENSO and resulting dry conditions caused the reproductive failure of 1998, possibly by reducing prey availability.

Previous studies on *S. mucronatus* showed that litter size is regulated by follicular atresia after vitellogenesis (Méndez-de la Cruz et al. 1993). A high elevation population from Monte Alegre, Distrito Federal (3200 m elev.), exhibited a 50% reduction in litter size compared to a lowland population from Tecocomulco, Hidalgo (2600 m elev.), even though the two populations did not differ in the initial number of vitellogenic follicles (Méndez-de la Cruz et al. 1993). Considering that each population produces the maximum number of vitellogenic follicles (Méndez-de la Cruz et al. 1993), the lizards in our study apparently had an even greater percentage of follicular atresia, as litter sizes of females collected during 1996–1997 were smaller than those from the Monte Alegre and Tecocomulco populations ($F_{1,3} = 24.07$; $P = 0.0001$). Atresia may have been as high as 100% in females collected during 1998 (Table 1).

Acknowledgments.—We thank Robin Andrews for improving the manuscript, Gustavo Casas-Andreu, two anonymous referees, and especially Barbara A. Savitzky for critically reading the manuscript and providing editorial assistance. We also thank Oswaldo Hernández and Gabriel Barrios for help with fieldwork. The present research was funded by projects CONACYT (400355-5-2155) and DGAPA (IN232398).

The Non-Fish, Vertebrate Diet of Sympatric Populations of the Cottonmouth (*Agkistrodon piscivorus*) and Northern Watersnake (*Nerodia sipedon*)

JOHN G. HIMES*
University of Southern Mississippi, Department of Biological Sciences Box 5018, Hattiesburg, Mississippi 39406-5018, USA

**Present Address: Texas Parks and Wildlife Department Middle Trinity River Ecosystems Project, 16149 North US Highway 287 Tennessee Colony, Texas 75861-3005, USA; e-mail: johnhimes@direcway.com*

The diets of the cottonmouth (*Agkistrodon piscivorus*) and northern watersnake (*Nerodia sipedon*) have been studied in detail (e.g., Kofron 1978; Meyer 1992). However, a comparison of food habits has not been made between these species in areas where they occur in sympatry along the Gulf of Mexico coastal plain, USA. Tributaries of rivers in the Gulf coastal plain often support large, sympatric populations of *A. piscivorus* and *N. sipedon* (pers. obs.). These species generally are non-specialized, opportunistic feeders that exhibit similar daily and seasonal activity patterns (Burkett 1966; Diener 1957). Moreover, where these snakes inhabit the same areas, both species tend to select habitats that contain abundant aquatic vegetation and woody debris such as logjams and half-submerged brushpiles (pers. obs.). Thus, these species appear to exhibit similar life histories and, where they occur in sympatry, may potentially compete for food resources.

Despite the typically euryphagic food habits of *A. piscivorus* and *N. sipedon*, reptiles may exhibit specific food preferences when occurring in sympatry, perhaps to lessen the potential for competition (e.g., Fitch 1982; James 1991; Moll 1990). The food habits of *A. piscivorus* and *Nerodia* spp. also are influenced in part by snake sizes: small (juvenile) and large (adult) snakes differ in foraging behavior (Burkett 1966; Mushinsky et al. 1982; Savitzky 1989) and gape sizes (Forsman 1996; Miller and Mushinsky 1990; Mushinsky et al. 1982), which may result in access to and acquisition of different prey taxa. Ontogenetic shifts in diet may further affect potential competitive relationships among and between *A. piscivorus* and *N. sipedon*. For example, according to optimal foraging theory (Pyke et al. 1977; Schoener 1971), large predator (e.g., snake) individuals are expected to "drop" small prey from their diet, and individuals of the same approximate size are expected to exhibit higher dietary overlap than do individuals of disparate sizes (reviewed by Arnold 1993).

To determine food habits of snakes, I examined preserved museum specimens of *A. piscivorus* and *N. sipedon* collected over a 48-year period (1951–1999) from the Chattahoochee, Choctawhatchee, Yellow, Escambia, Alabama, Tombigbee, Pascagoula, Pearl, and Mississippi river systems of western Georgia, western Florida, Alabama, Mississippi, and southeastern Louisiana. I surveyed all specimen localities at night on foot and for up to five times and only compared food habits between *A. piscivorus* and *N. sipedon* collected from sites where I observed individuals of both species in sympatry ($\leq$ 11.2 m from each other). Snakes were dissected and food items were removed from the esophagus and stomach, identified to the lowest possible taxon, and grouped according to the species and size class of snake (small: < 50 cm snout–vent length [SVL]; large: $\geq$ 50 cm SVL). The accurate calculation of prey sizes and masses was not feasible due to the advanced digestion and the poor preservation states of food items in most snakes.

I dissected a total of 359 *A. piscivorus* and 661 *N. sipedon* collected from sites where the species occur in sympatry (pers. obs.). Of these, 85 specimens of *A. piscivorus* and 23 specimens of *N. sipedon* contained non-fish vertebrate food items. Forty-three and 41 of the 84 specimens of *A. piscivorus* were allocated to the small and large size classes, respectively (small: mean SVL = 31.33 cm ± 2.48 [95% CI], range = 18–49 cm; large: mean SVL = 64.93 cm ± 3.17, range = 50–90 cm). Twelve and 11 of the 23 specimens of *N. sipedon* were allocated to the small and large size classes, respectively (small: mean SVL = 30.75 cm ± 7.53, range = 16–48 cm; large: mean SVL = 73.91 cm ± 13.74, range = 53–116 cm).

A Simpson's diversity index was used to compare diets within each species and size class of snake: $D = 1/SP^2_i$, where P_i is the proportion of prey individuals in species i that contributes to the total sample of prey within that species (Began et al. 1996). A

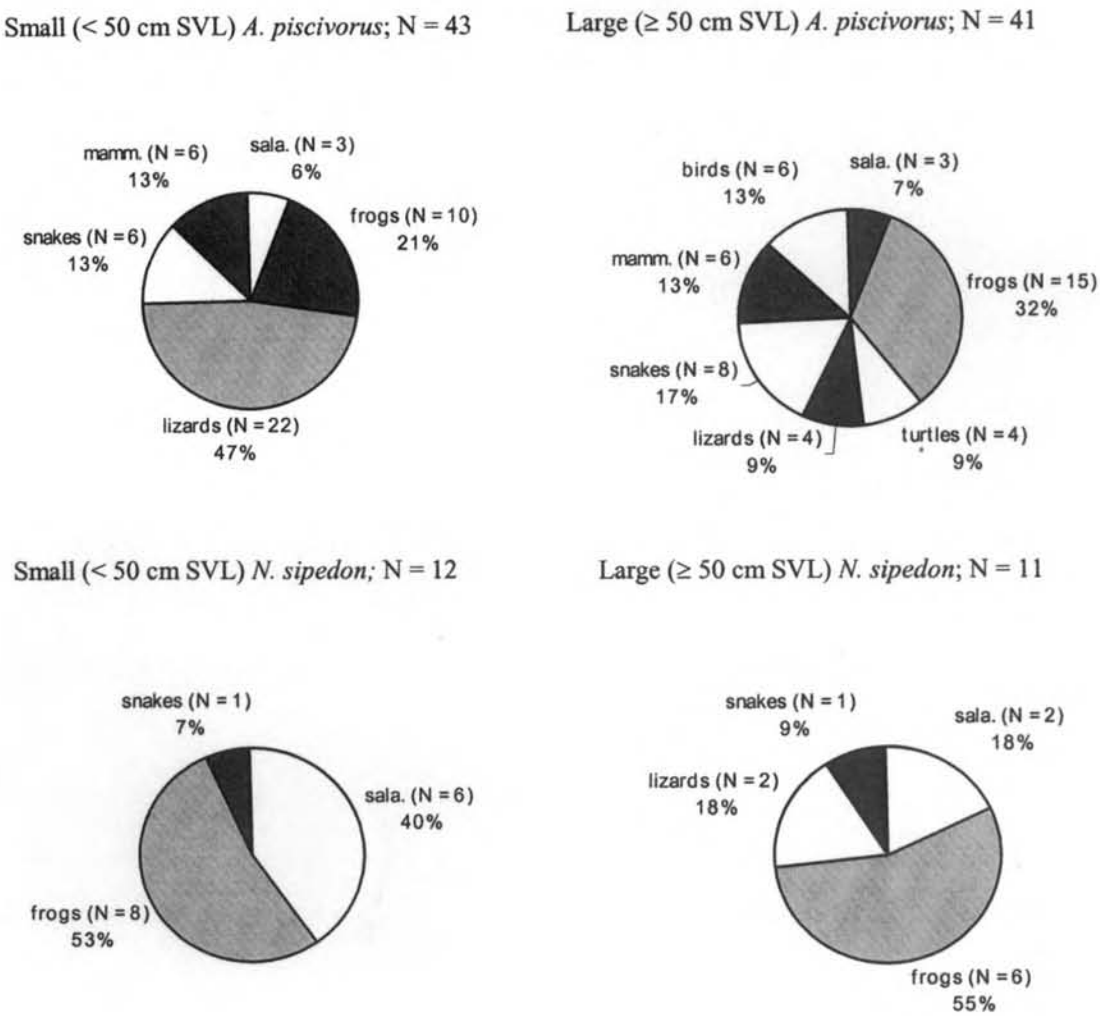

FIG. 1. Non-fish vertebrate food items obtained from *Agkistrodon piscivorus* and *Nerodia sipedon*. Sample sizes refer to the number of snakes containing identifiable food items. sala. = salamanders, mamm. = mammals.

Morisita's index of overlap was used to compare diets between species and size classes of snake: $I_M = 2Sx_iy_i/([l_1 + l_2]N_1N_2)$, where x_i is the total number of prey individuals in species i in community 1, y_i is the total number of prey individuals in species i in community 2, N_1 is the total number of prey individuals in community 1, and N_2 is the total number of prey individuals in community 2 (Brower et al. 1998).

Comparisons of fish and invertebrate components of snake diets indicated that niche breadth was relatively high among small *A. piscivorus*, intermediate among small *N. sipedon*, and relatively low among large *A. piscivorus* and *N. sipedon* (Himes 2002, 2003). Dietary overlap between *A. piscivorus* and *N. sipedon* was very low (regardless of snake size), although overlap between small and large *N sipedon* was very high (Himes 2002, 2003).

Examination of the vertebrate components of snake diets yielded a total of four families, five genera, and four species of caudates, and three families, four genera, and four species of anurans. However, of those amphibians identified to species, only *Rana sphenocephala* was found in both *A. piscivorus* and *N. sipedon*. A total of three families, two genera, and two species of turtles were found in *A. piscivorus*. A total of five families, genera, and species of lizard, and two families, eight genera, and nine species of snakes were identified. All but two individuals each of lizards and snakes were found in *A. piscivorus*, and of those reptiles that were identified to species, none was found in both *A. piscivorus* and *N. sipedon*. One specimen each of *A. piscivorus* and *N. sipedon* contained a conspecific. Two species of passerine birds (each from different families), three species of soricid insectivores, and one species of murid rodent were found in *A. piscivorus*. Of these, five prey species (a lizard, three snakes, and a bird) represented new records for *A. piscivorus* (Table 1).

Simpson's index indicated that dietary diversity was highest in large *A. piscivorus*, intermediate in small *A. piscivorus* and large *N. sipedon*, and lowest in small *N. sipedon* (Table 2). The highest and lowest diversities are respectively attributable in part to only the large *A. piscivorus* containing turtles and birds, and the small *N. sipedon* containing only salamanders and frogs, with the exception of an individual prey snake. Thus, among the small and large *N. sipedon*, only large snakes contained lizards. In turn, only *A. piscivorus* contained mammals, turtles, and birds, although turtles and birds were only found in large snakes. Frogs were most abundant in large *A. piscivorus*, and large and small *N. sipedon*. However, lizards were most abundant in small *A. piscivorus* (Fig. 1).

Morisita's index indicated that dietary overlap was high between large *A. piscivorus* and *N. sipedon*, with both containing salamanders, frogs (the most abundant food item in both species), lizards, and snakes. Overlap was also high between small and large *N. sipedon*, with both size classes containing salamanders, frogs (the most abundant food item in both size classes), and snakes. Overlap was intermediate between small and large *A. piscivorus*, with both size classes containing salamanders, frogs, lizards, snakes, and mammals. However, only large *A. piscivorus* contained birds and turtles, and lizards (rather than frogs) were the most abundant food item in small snakes. Overlap was relatively low between small *N. sipedon* and *A. piscivorus*. Lizards, which were absent in *N. sipedon*, were the most abundant food item in *A. piscivorus*, and only *A. piscivorus* contained mammals (Table 2).

According to these data, *A. piscivorus* consumes a wide diversity of non-fish vertebrates that includes amphibians (particularly frogs in large snakes), reptiles (particularly lizards in small snakes), mammals, and birds, whereas *N. sipedon* consumes primarily amphibians (particularly frogs). Among amphibians, three of four families of caudates (Ambystomatidae, Amphiumidae, Proteidae) were only found in *A. piscivorus*, and only one species of anuran (*Rana sphenocephala*) was found in both species of snake (Table 1). Dietary overlap of non-fish vertebrates was relatively low between small *A. piscivorus* and *N. sipedon*. Although dietary overlap of non-fish vertebrates was high between large snakes, overlap of fishes (by family), which comprised over 50% of all food items identified from large *A. piscivorus* and *N. sipedon*, was very low (Himes 2002, 2003). Thus, *A. piscivorus* and *N. sipedon* appear to exhibit different food habits, which may lessen the potential for interspecific competition (assuming food is limited) and enable large populations of these species to coexist

over a large area of the Gulf coastal plain.

Snakes may undergo ontogenetic shifts in diet for several reasons, which may be either environmentally or genetically induced. More specifically, Mushinsky and Miller (1993) suggested that the high vulnerability of young snakes to predation may be a driving force in snake evolution because 1) "young individuals forage on different prey than [do] larger conspecifics", 2) the "young of species that are uniformly colored as adults often do not resemble their parents" (although this does not apply to *N. sipedon*, which is strongly patterned throughout life), 3) "relative to SVL, head width and length (elements associated with foraging capabilities) are greater in smaller individuals than [in] larger conspecifics", and 4) "relative to SVL, smaller individuals forage on larger prey (by mass) than [do] conspecific adults". Therefore, the food habits of young snakes often differ from those of adult conspecifics due in part to high predation pressure, which probably accounts for some of the dietary differences between small and large *A. piscivorus* (Himes, 2002, 2003).

For example, compared to adults, young *A. piscivorus* spend more time foraging at the land-water interface than do adults (Savitzky 1992), thereby avoiding areas of open water where aquatic predators (including adult conspecifics) are more plentiful and thus predation pressure is higher. This foraging strategy probably accounts for the large lizard component found in the diet of small snakes in this study. In addition, terrestrial foraging by juvenile *A. piscivorus* may serve several other purposes: 1) lessening intraspecific competition for food with other juveniles and adults, 2) lessening interspecific competition for food with juvenile *N. sipedon*, and 3) adding diversity to the diet (Himes 2002). The light-colored tail tip of juvenile *A. piscivorus* and other viperids, which generally darkens in subadults to match the remainder of the body coloration, is twitched to attract small terrestrial prey, particularly lizards (reviewed by Heatwole and Davison 1976). Therefore, it appears that juvenile *A. piscivorus* are morphologically specialized to exploit a food source that is not as frequently utilized by the adults (see also Wharton 1969).

By contrast, as overlap was extremely high between small and large *N. sipedon*, this species does not appear to undergo an ontogenetic shift in diet (Table 2). This relationship is particularly evident when considering fishes as prey, which comprised over 50% of all food items identified from both small and large snakes. Overlap of fishes by family was also very high between small and large snakes (Himes 2002, 2003). Additionally, unlike *A. piscivorus*, *N. sipedon* bears a similar coloration and pattern throughout life. Thus, if external morphology is related to or affects aspects of the life history of snakes such as habitat selection, which in turn may determine the available prey base and foraging opportunities, then snakes that do not undergo ontogenetic shifts in color or pattern (such as *N. sipedon*) may not exhibit a corresponding ontogenetic shift in habitat selection or diet.

The results of this study support the findings of Clark (1949) and Kofron (1978) that *A. piscivorus* has a more diverse diet than do sympatric species of *Nerodia* in the Atchafalaya River Basin of south-central Louisiana (Clark 1949) and the hill parishes of north-central Louisiana (Kofron 1978). They found that *A. piscivorus* consumed fishes, anurans, serpents, and mammals. However, unlike the specimens of *A. piscivorus* examined in my study, lizards were absent from the diets of snakes. Although *N. sipedon* is absent from both areas, several other species of aquatic snakes may be sympatric with *A. piscivorus*: *Nerodia cyclopion*, *Nerodia*

TABLE 2. Simpson's diversity index (*D*) and Morisita's index of overlap (I_M) values for respectively comparing diets within (first column) and between (third column) small (SVL < 50 cm) and large (SVL ≥ 50 cm SVL) specimens of *Agkistrodon piscivorus* and *Nerodia sipedon*.

size class and species	*D*	size class and species	I_M
small *A. piscivorus*	0.71	large *A. piscivorus*	0.67
small *N. sipedon*	0.83	large *N. sipedon*	0.42
small / large *A. piscivorus*	0.59	small *A. piscivorus* / *N. sipedon*	0.92
large *A. piscivorus* / *N. sipedon*	0.69	small / large *N. sipedon*	1.03

fasciata, and *Nerodia rhombifer* consumed only fishes (primarily) and anurans (secondarily), *Nerodia erythrogaster* consumed only anurans, and *Regina grahamii* and *Regina rigida* consumed only crayfishes. These findings, combined with those of numerous other studies (reviewed by Gloyd and Conant 1990; Savitzky 1992) including my own, clearly indicate that the euryphagic feeding habits of *A. piscivorus* are widespread throughout the range of this species. The finding of *Sceloporus undulatus*, *Coluber constrictor*, *Diadophis punctatus*, *Virginia striatula*, and *Baelophus bicolor* adds to the list of food items reported for *A. piscivorus*; this is not surprising given the opportunistic feeding habits of *A. piscivorus* and availability of prey species.

Unlike the specimens of *N. sipedon* examined in my study, snakes examined from northeastern Kansas consumed exclusively frogs (Fitch 1982), snakes from western North Carolina often contained crayfishes, and snakes from southwestern Kansas lacked non-fish vertebrates (Diener 1957). Although *A. piscivorus* is absent from all of these areas, *N. erythrogaster* is sometimes sympatric with *N. sipedon* in Kansas. However, the respective diets of *N. sipedon* and *N. erythrogaster* consist almost exclusively of fishes and anurans (Diener 1957), and thus snakes do not appear to compete for food. Also by contrast to the specimens of *N. sipedon* examined in my study, over 50% of the food volume of snakes from south-central Georgia consisted of salamanders, *Necturus* (Camp et al. 1980). However, similar to the results of my study, frogs and toads were the most abundant non-fish vertebrate food items in the diets of snakes from New York (Brown 1940) and Michigan (Meyer 1992).

The results of experimental chemical tests indicate that *N. sipedon* has as innate preference for the scent of amphibians (and fishes), as exhibited by predatory behavior (Burghardt 1968; Dix 1968), thereby accounting for its narrower prey preferences relative to *A. piscivorus*. Thus, the source of the more specific food habits of *N. sipedon* may be genetic, and not directly related to the presence or absence of *A. piscivorus*, although preferences may be subsequently environmentally modified (e.g., by potential competitive interactions) (Dix 1968).

I dissected snakes that were collected over a 48-year period and from nine different river systems associated with the Gulf of Mexico. The prey base available to snakes is unlikely to be the same between these drainages, especially with regards to potential prey fishes (Mettee et al. 1996; Ross 2002), and the composition of the prey base is subject to temporal changes (both seasonal and yearly) in response to hydrological changes in these river systems. Therefore, caution should be drawn when comparing the results of my study to those of other studies. Nonetheless, because the snakes from my study were collected over a wide area (including all major river systems in the southern extremity of distribution of *N. sipedon*; Tennant and Bartlett 2000) and comprised a large sample, valid generalizations about the food habits of snakes can readily be made on a broader geographic scale, as well as for snakes in areas where *A. piscivorus* and *N. sipedon* occur in sympatry.

Acknowledgments.—I thank D. Beckett, F. Moore, S. Ross, S. Secor, and S. Walls for their input. Permission was granted to conduct dissections by H. Dundee (Tulane University), R. Jones (Mississippi Museum of Natural Science), B. Kuhajda (University of Alabama), J. McGuire (Louisiana State University), and D. Nelson (University of South Alabama). Assistance with dissections and identification of food items was provided by B. Alford, V. Briggs, D. Cimprich, E. Ducote, S. Herger, S. Pierce, P. Schweizer, and A. Trousdale.

Caecilians are tropical, limbless, primarily fossorial amphibians (Duellman and Trueb 1986). Although they may be fairly abundant in certain areas (Péfaur et al. 1987), their subterranean habits make them difficult to find and as a result, life histories are unknown for most of the 167 described species (for examples of studies that have documented caecilian life histories, see Gans 1961; Parker 1936, 1958; Sanderson 1937; Sarasin and Sarasin 1887–90; Taylor 1968; Wake 1980). Information on caecilian life histories is important not only for improving understanding of amphibian life history evolution, but also for developing management strategies for conservation. For example, life history data can be used to conduct ecological sensitivity analyses to infer which human activities are most likely to negatively impact caecilian populations (Biek et al. 2002).

Even such general information as reproductive mode remains unknown for many caecilian species (Wake 1992). Caecilians have a variety of reproductive modes including oviparity with aquatic larvae, oviparity with direct development, and viviparity (Wake 1977, 1992; Wilkinson and Nussbaum 1998). A large percentage of caecilians are viviparous, although the exact percentage of viviparous species remains controversial because of differences in opinion on which criteria are acceptable for inferring reproductive mode (Wake 1977; Wilkinson and Nussbaum 1998).

The family Caeciliidae, the largest family of caecilians, contains both oviparous and viviparous species (Gans 1961; Peters 1874, 1875; Sanderson 1937; Wake 1977, 1992; Wilkinson and Nussbaum 1998). However, reproductive mode has not been reported for any of the 33 described species in the genus *Caecilia*, the most speciose genus in the family Caeciliidae and one of the two largest genera in the entire order (AmphibiaWeb 2003). To date, evidence suggests that *Caecilia* species are oviparous or that some are oviparous and others are viviparous (Taylor 1968; Tschudi 1839; Wake 1977). Wilkinson and Nussbaum (1998) reported observing an unspecified *Caecilia* species lay eggs in captivity. Observations of large ova and larvae with gill slits have also been used to infer that some *Caecilia* species are oviparous (Tschudi 1839; Wake 1977, 1992). The presence of fetal teeth in other *Caecilia* species suggest that these species may be viviparous (Taylor 1968). However, the only conclusive evidence for reproductive mode is documentation of parturition, laid eggs, aquatic larvae, or oviductal fetuses for specific species.

In January 2001, we began an inventory of the amphibians of Yanayacu Biological Station, Ecuador, located at approximately 2100 m on the east side of the Cordillera Oriental of the Andes in Provincia Napo at 00°35'S 77°53'W. Yanayacu is surrounded by cloud forest with a 20–25 m high canopy as well as some pasture. On 16 January 2001, we found a clutch of *Caecilia orientalis* (Taylor 1968) eggs (Fig. 1), an adult female, two adult males, and one

Fig. 1. Clutch of *Caecilia orientalis* eggs found at Yanayacu Biological Station near Cosanga, Provincia Napo, Ecuador (2100 m elev.).

TABLE 1. Body measurements and primary and secondary annular counts of adult *Caecilia orientalis* and number and length of ovarian ova found in dissected females. One female (QCAZ 21417) and the two males (QCAZ 21418–21419) were found with the clutch of eggs reported in this article at Yanayacu Biological Station near Cosanga, Provincia Napo, Ecuador (2100 m). Baeza is also located in Provincia Napo at an elevation of 1990 m.

QCAZ	Sampling location	Month collected	Sex	Body measurements (mm)			Annuli (prim / sec)	Ova	
				Total length	Head length	Width at mid-body		Number	Length (mm)
2311	Baeza	August	F	400	10.7	10.5	116 / 139	120	< 1.5
6987	Cosanga	November	F	363	9.9	9.4	118 / 96	30	1.5–2.5
								110	< 1.5
6988	Cosanga	November	F	310	9.3	8.9	114 / 98	22	1.5–2.5
								115	< 1.5
21417	Yanayacu	January	F	625	13.5	15.2	122 / 208	7	3.5–5.7
								110	< 1.5
21418	Yanayacu	January	M	406	10.0	11.8	114 / 119	NA	NA
21419	Yanayacu	January	M	427	10.0	12.0	112 / 123	NA	NA

other individual that escaped capture underneath a large, highly decomposed log in pasture bordered by secondary cloud forest (Fig. 2). The clutch was almost certainly a *C. orientalis* clutch because no other caecilians have been documented at the site after two years of inventory work. All three captured adults were preserved as vouchers and stored at the Museo de Zoología of the Pontificia Universidad Católica del Ecuador in Quito, Ecuador (QCAZ; Table 1). The female (QCAZ 21417) was much larger than the two males (QCAZ 21418–21419) and the individual that escaped appeared to be a male based on its small size. The nest site was very wet and was several meters from a small 1 m wide creek. The female was found approximately 5 cm from the clutch and one of the males was approximately 5 cm from the female. The second male and the individual that escaped were found approximately 30 cm and 150 cm, respectively, from the other two adults.

The *C. orientalis* clutch had a total of seven eggs (Fig. 1). The eggs were connected to each other by cords attached to both ends of each egg. The eggs were transparent so that embryos could be seen inside. Embryos had distinct dark eyes, feathery external gills, and creamy yellow yolk sacs and moved when the eggs were touched. The lengths and diameters of three of the eggs were measured. The lengths of these eggs were 10.6 mm, 10.3 mm, and 10.2 mm (mean $\pm$ SE = 10.4 $\pm$ 0.1 mm) and the diameters in the same order were 8.8 mm, 8.3 mm, and 8.1 mm (mean $\pm$ SE = 8.4 $\pm$ 0.2 mm). Two of the seven eggs were preserved as vouchers on January 21, 2001 (QCAZ 21420). The remaining five eggs were given to Oscar Pérez and Eugenia M. del Pino in the Departamento de Ciencias Biológicas at the Pontificia Universidad Católica del Ecuador for study of the development of the embryos.

The observation of a clutch of *C. orientalis* eggs clearly demonstrates that this species is oviparous. Wilkinson and Nussbaum (1998) also report egg laying in a *Caecilia* species in captivity, but they do not specify which species was observed. Nonetheless, their observation and ours suggest that oviparity may be the predominant reproductive mode in the genus. Wake (1992) hypothesized that *C. pressula* and *C. subnigricans* are viviparous based on observation of fetal teeth. However, it has been suggested that fetal teeth are not a reliable character for inferring reproductive mode because some *Siphonops* possess what have been called fetal teeth, yet are known to be oviparous (Wilkinson and Nussbaum 1998).

The observation that the clutch was found several meters from a small stream also suggests that *C. orientalis* has direct develop-

FIG. 2. Site where *Caecilia orientalis* clutch, adult female, two adult males, and one other individual were found underneath a large, highly decomposed log at Yanayacu Biological Station.

ment with no aquatic larval stage. If *C. orientalis* had an aquatic larval stage, it seems more likely that the female would have laid the clutch directly adjacent to the stream to provide easy access to the water for recently hatched larvae as is the case in *Ichthyophis glutinosus* (Sarasin and Sarasin 1887–90).

Our observation of a female *C. orientalis* by the clutch suggests that she was attending her eggs as has been documented for other oviparous species of caecilians (Breckenridge and Jayasinghe 1979; Sanderson 1937; Sarasin and Sarasin 1887–90). However, we are unaware of any previous reports of male caecilians at nest sites. One possible explanation for why males were found at the nest site is that they were simply sharing a preferred microhabitat with the female. Another possibility is that the males were attempting to mate with the female. Finally, the male found closest to the female and closest to the eggs may have been the father of the eggs and may have also been attending them. This would be the first known case of biparental care in caecilians.

We also dissected the female *C. orientalis* found with the clutch and three additional females previously collected as vouchers from Provincia Napo, Ecuador, to count and measure ovarian ova (Table 1). All four females had large numbers of ova (mean $\pm$ SE = 129 $\pm$ 6 ova). Most ova were small ($<$ 1.5 mm), although the female found with the clutch (QCAZ 21417) contained seven ova ranging from 3.5–5.7 mm long and two of the other females (QCAZ 6987–6988) had 30 and 22 medium-sized ova, respectively, ranging from 1.5–2.5 mm long. The different sizes of ova likely represent different stages of development as documented in *Gymnopis multiplicata* (Wake 1968) and *Dermophis mexicanus* (Wake 1980).

The temporal sequence of ova maturation in the dissected females suggests that reproduction is seasonal in *C. orientalis* (Table 1). The observation of female QCAZ 21417 with a laid clutch of eggs on January 16 shows that ovulation starts by January, the beginning of the rainy season at Yanayacu Biological Station (Harold Greeney, owner and Station Manager of Yanayacu, pers. comm.). The female found in August had only very small ova, suggesting reproductive quiescence during this dry period of the year. The two females found in November have medium-sized ova indicating that by this point, vitellogenesis is occurring. This seasonal reproductive pattern matches that reported for *Dermophis mexicanus* in which birth occurs at the beginning of the rainy season (Wake 1980).

The observation that female QCAZ 21417 had mature ovarian ova at the same time she was guarding the reported clutch also suggests that *C. orientalis* is able to produce two clutches per rainy season. This conclusion is supported by the observation that *C. orientalis* females found after the rainy season (QCAZ 2311, 6987–6988) do not have mature ova. Thus, female QCAZ 21417 likely would have laid her mature ovarian ova later during the same rainy season in which she was caught. This frequency of parturition is four times greater than that observed in *Dermophis mexicanus* which only gives birth once every other year (Wake 1980). The slower rate of parturition in *D. mexicanus* is likely due to the long gestation period observed in this viviparous species (Wake 1980).

Acknowledgments.—We thank Luis A. Coloma, P. Stephen Corn, Bryce Maxell, Andrew Sheldon, and Marvalee H. Wake for reviewing drafts of this paper. Specimens from sites other than Yanayacu were collected by Giovanni Onore (QCAZ 2311), Felipe Campos, and Marisol Ayala (QCAZ 6987–6988). Funding for this project was provided by a Conservation, Food & Health Foundation grant awarded to the Population Biology Foundation and a National Science Foundation Graduate Research Traineeship awarded to WCF (DGE 9553611). We would also like to thank Harold Greeney for providing accommodations at Yanayacu Biological Station. Research permits for this project were obtained from the Ministerio del Ambiente (number 029-IC-FAU-DFP). This project was approved by the University of Montana Institutional Animal Care and Use Committee (number ACC 034-00). This is publication number 71 of the Yanayacu Natural History Research Group.

Lizards in the genus *Phrynosoma* are, in general, dietary specialists on ants (Pianka and Parker 1975), with the ability to digest and detoxify their ant prey (Schmidt et al. 1989). While most *Phrynosoma* appear to be ant specialists, there may be flexibility and variability both among populations and among species. For example, Suarez et al. (2000) found that *P. coronatum* shift their diet away from ants in areas dominated by the invasive Argentine ant (*Linepithema humile*), which are not eaten and apparently eliminate palatable ant species.

Much of the information on *Phrynosoma* diets comes from populations in the United States (e.g., Bott et al. 2001; Munger 1984a,b; Pianka and Parker 1975; Rissing 1981; Shaffer and Whitford 1981; Suarez et al. 2000; Whitford and Bryant 1979). Less is known about the diets of the Mexican species (e.g., Blackshear and Richerson 1999; Pianka and Parker 1975). We report on the diets of four species of Mexican *Phrynosoma*: *P. asio* and *P. taurus* from Guerrero, and *P. cornutum* and *P. modestum* from Chihuahua.

Phrynosoma asio were collected opportunistically from 1993 to 1998 with nine collected from May to August, and one collected in January from the Cañon del Zopilote (600 m elevation; ca. 17°33'N, 99°30'W), north of Chilpancingo, Guerrero, and 14 km south of Mezcala. *Phrynosoma asio* is abundant on the hills on both sides of Río Zopilote, a tributary of the Río Balsas. Dominant vegetation at Cañon del Zopilote includes a variety of cacti, including *Neobuxbaumia* sp.; several species of *Bursera* and *Acacia*, *Lysiloma tergemina*, *Mimosa benthamia*, *Ficus continifolia*, *F. petiolaris*, and *Pithecellobium dulce*.

Phrynosoma taurus were collected opportunistically between 1996 and 1998 with 11 collected in June and one in August. The study site (1200 m elevation; 17°38'10.9"N, 99°32'42.08"W) was 3.25 km southwest of Zumpango del Río, Guerrero. *Phrynosoma taurus* is rare at this site (pers. obs.), found only on steep hills in the middle of the morning. Dominant vegetation at Zumpango del Río includes *Bursera* spp., *Acacia* spp., *Pithecellobium dulce*, and

Mimosa sp.

Phrynosoma cornutum and *P. modestum* were collected at the Bolson Cabeza de Vaca, the extensive sand dune areas of northern Chihuahua (31°10' – 31°40'N, 106°13' – 107°30'W). Both species were collected opportunistically in 1997 and 1998 in June or July (7 *P. modestum*, 5 *P. cornutum*), and October (5 *P. modestum*, 5 *P. cornutum*). This area is dedicated to livestock grazing and free of agricultural cultivation. *Phrynosoma* are abundant in the sand dunes, and most specimens were opportunistically caught crossing gravel roads in late afternoon.

Lizards were collected by hand, preserved shortly after collection (initially in 10% formalin, and finally in 70% ethanol; specimens deposited in the Laboratorio de Ecología of the Unidad de Biología, Tecnología y Prototipos), measured (snout–vent length [SVL] to the nearest mm), and dissected to examine stomach contents. Diet items were identified to family where possible, and percent of prey volume for each taxa was calculated for each stomach (estimated by volumetric displacement).

Sample sizes were low (10 or 12 stomachs) for all species. In part this was because of the difficulty in collecting lizards, but also effort was made to minimize impacts on these populations. A recent rarefaction analysis suggests that samples of ≥ 10 can exhibit > 90% of a species' prey items (Winemiller et al. 2001).

The diet of *P. asio* (10 stomachs examined; all contained prey) was dominated by ants, in particular *Octostruma* sp., *Camponotus* sp., and *Pagomyrmex* sp., but non-ant insects contributed substantially to the diet (Table 1). Indeed, the most numerically important single prey item was termites because of one individual with 240 termites in its stomach. The Simpson's Diversity Index for the diet of this species was 5.96, mean Simpson's index for individuals was 1.45 ± 0.29 (range = 1–4). The only other previous report on *P. asio* diets found that about 75.3% of the diet numerically and 31.1% of the diet volumetrically were ants (Pianka and Parker 1975), which is consistent with our results.

The diet of *P. cornutum* (10 stomachs examined; all contained prey) was also dominated by ants, in particular *Messor* sp. and *Aphaenogaster* sp. (Table 2). Non-ant insects contributed volumetrically to the diet although they were relatively unimportant numerically. We also found lizard skin in one stomach. The Simpson's Diversity Index for the diet of this species was 4.45, mean Simpson's index for individuals 1.42 ± 0.17 (range = 1–2.7). Several previous studies on *P. cornutum* have demonstrated that the vast majority of their diet is made up of ants and other hymenopterans, such as velvet ants (Mutillidae) (e.g., Barbault and Maury 1981; Blackshear and Richerson 1999; Manley and Sherbrooke 2001; Pianka and Parker 1975; Whitford and Bryant 1979), as well as termites (Bott et al. 2001).

The diet of *P. modestum* (12 stomachs examined; one [8.3%] was empty) consisted almost exclusively of ants, in particular *Camponotus* sp., *Octostruma* sp., and *Messor* sp. (Table 3). Non-ant insects contributed relatively little numerically and volumetrically to the diet. We found lizard skin in one stomach, and nematodes (probably parasites) in another. The Simpson's Diversity Index for the diet of this species was 7.09, mean Simpson's index

for individuals was 1.35 ± 0.13 if only lizards with prey are included (range = 1–2.4), and 1.24 ± 0.16 if all lizards are included. Previous studies on the diets of *P. modestum* also found a diet of ants predominating (e.g., Barbault et al. 1978; Shaffer and Whitford 1981), although this can vary seasonally (Barbault and Maury 1981).

The diet of *P. taurus* (12 stomachs examined; two [16.6%] were empty) consisted primarily of insects (Table 4). On the basis of the number of items consumed, *Oligomyrmex* sp. was the most important; however, this numerical dominance can be attributed to a single individual with 360 *Oligomyrmex* ants in its stomach. Without this one stomach, the most important prey items were a variety of insects, including lepidopteran larvae, calliphorid flies, and scarabid beetles. The Simpson's Diversity Index for the diet of this species was 1.74, mean Simpson's index for individuals was 1.79 ± 0.35 if only lizards with prey are included (range = 1–4.5), and 1.49 ± 0.35 if all lizards are included. Pianka and Parker (1975) reported that, in *P. taurus*, ants made up 47.4% of the diet numerically and 56.5% of the diet volumetrically.

As expected, ants are an important food for all four species of *Phrynosoma* we studied. All species appeared to take other insects opportunistically, and in *P. taurus* other insect groups appeared to be at least as important as ants. Indeed, if one looks at the proportion of prey items that are ants (either numerically or volumetrically) as an index of specialization on ants, *P. taurus* has the least specialized diet, followed closely by *P. asio*. Both *P. cornutum* and *P. modestum* have very specialized diets, with about 95% of all prey items being ants. This relative ranking of ant specialization among these four species is generally consistent with results presented in Pianka and Parker (1975), although the use of ants in the diets are consistently higher in our study.

While at the species level numerous genera of ants were eaten, at the individual lizard level each stomach generally contained a single genus of ant. Such a result would be expected if horned lizards were foraging at ant colony openings or along foraging columns of ants (e.g., Munger 1984a) as opposed to haphazard encounters of single ants (e.g., Whitford and Bryant 1979). It appears that *P. asio* will also forage at the openings of termite mounds, as one individual had 240 termites in its gut. Bott et al. (2001) recently observed *P. cornutum* foraging on termite alates at the opening of a termite mound.

The leaf litter on the floor of tropical forests harbors a diversity of invertebrates and vertebrates, these latter being mainly small reptiles and amphibians (Vitt and Caldwell 1994). In these habitats, the abundance and variety of food resources seem to influence the anuran community, as has been found for litter frogs in Panama and Peru (Toft 1980a,b). Several studies found a relationship between body size and prey size of litter anurans, where the differential use of prey by individual species seemed to correlate with the snout–urostyle length (SUL) of frogs, thus favoring resource partitioning (Caldwell 1996; Lima and Moreira 1993; Toft 1980b, 1981, 1995; Vitt and Caldwell 1994). Anurans do not chew their food and thus they are limited to eating prey that fits in their mouths, and this may cause a shift in prey size simply because the mean sizes of individual arthropod prey differ among orders (Lima and Moreira 1993). Based on her studies, Toft (1980a,b) categorized leaf-litter leptodactylid frog species as "non-ant specialists" because their diets consisted predominantly of soft-bodied, mobile arthropods such as crickets and large spiders.

The anuran genus *Eleutherodactylus*, family Leptodactylidae, is the most speciose (over 500 species) among amphibians (Lynch 1996). These frogs are common inhabitants of the leaf litter floor in tropical forests of Central and South America and the West Indies (Lynch 1996). *Eleutherodactylus* species typically are carnivorous, feeding mainly on arthropods (Duellman 1978; Ovaska1991; Toft 1980a,b).

Eleutherodactylus parvus occurs in forest floor litter communities in the Atlantic Rainforest of the states of Rio de Janeiro and São Paulo in southeastern Brazil (Haddad and Sazima 1992). In the litter anuran community in the Atlantic Rainforest of Ilha Grande, south of Rio de Janeiro State, *E. parvus* is one of the most common species found (Rocha et al. 2001). Despite being a common species, previous research on *E. parvus* has focused on morphology, systematics, or biogeography (Haddad and Sazima 1992; Heyer et al. 1990; Lynch 1976); no information is available on aspects of its ecology. In this study we analyzed the diet of *E. parvus*, specifically addressing the following questions: i) What is the diet composition of this species? ii) To what extent do males and females differ in their diets? and iii) What is the relationship between frog size and prey size?

The study was carried out in a remnant of undisturbed Atlantic Rainforest at Ilha Grande (23°11'S, 44°12'W; 240 m above sea level), Rio de Janeiro State, southeastern Brazil. This is the largest island (19,000 ha) on the Rio de Janeiro coast and is covered by Atlantic Rainforest in different levels of regeneration (Rocha et al. 2000). Annual rainfall in the area is ca. 1700 mm and the mean annual temperature is ca. 23°C (Rocha et al. 2001).

Frogs were collected monthly between August 1996 and October 1997, in 2 x 1 m plots, randomly established on the forest floor. Additional frogs were collected in the same area in 8 x 8 m plots, also randomly established (see Rocha et al. 2001, for a detailed description of sampling methods). We recorded snout–urostyle length (SUL) and jaw width (JW) to the nearest 0.1 mm using a caliper. Difference in SUL between sexes was tested using one-way ANOVA (Zar 1999).

Diet composition and trophic diversity were analyzed in 62 individuals (44 females, 18 males) using a stereomicroscope and based on prey found in the stomachs. The prey items were identified to the taxonomic level of Order or Family (in the case of Formicidae), counted, and measured in three dimensions with a digital caliper (0.1 mm precision) to estimate their volume (Schoener 1967). All insect larvae were grouped as a single prey category. The mean length of the five longest items and the mean

TABLE 1. Frequency (number and % of frogs containing a particular prey type), N (total number and % of each item found in the frog stomachs), and volume of prey types (mm^3 and % of total volume) found in the stomachs of *Eleutherodactylus parvus* (N = 62) in the Atlantic Rainforest area of Ilha Grande, RJ, Brazil.

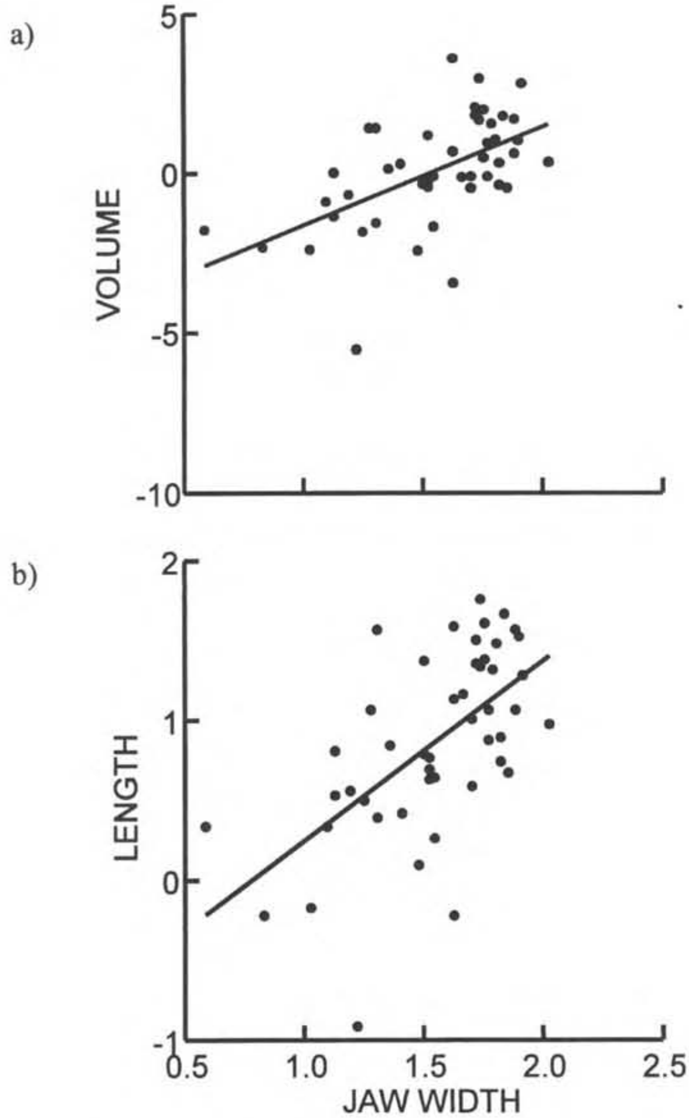

FIG. 1. Relationship between frog jaw width (in Log) and (a) mean volume of the five largest prey items (in Log) and (b) mean length of the five longest prey items ingested by *Eleutherodactylus parvus* (N = 62) at Ilha Grande, RJ, Brazil. ($F_{volume} = 19.44$; $R^2 = 0.30$; $P < 0.001$; $y = 1.10 + 0.69x$) ($F_{length} = 25.14$; $R^2 = 0.36$; $P < 0.001$; $y = 0.36 + 0.22x$).

volume of the five largest items were compared between sexes using the Mann-Whitney U test (Zar 1999). We calculated trophic diversity for adult males and females using Shannon-Wiener (H') index of diversity (Zar 1999) based on numeric percentages of prey types. Sexual differences in diet were compared using the t-test of Hutcheson (Zar 1999). We considered as adult males those frogs larger than 15 mm, the smallest body size of four *E. parvus* found calling at Ilha Grande Rainforest (unpubl. data) and as adult females, those larger than 17 mm, the smallest body size we found for 13 reproductive females (unpubl. data). To evaluate if items consumed by these frogs were size-limited and influenced by sex, we related mean volume of the five largest items and mean length (both log-transformed) of the five largest prey items consumed by each individual to the frog jaw width (log-transformed) using simple linear regression (Zar 1999).

Adults of *E. parvus* are sexually dimorphic in SUL, females (mean = 18.1 ± 0.6 mm, N = 13) being larger than males (mean = 15.4 ± 0.2 mm, N = 6) (t = 15.48; df = 18; $P < 0.001$). We found no significant ($P > 0.05$) difference in the mean length of the five largest items (U = 312.5) and mean volume of the five largest preys (U = 313.0) between males and females. Trophic niche diversity for males (H' = 0.747) and females (H' = 0.775) did not differ statistically (t = 0.317; df = 100; $P > 0.05$). For this reason we analyzed the diet for both sexes together.

Thirteen of the 62 individuals analyzed had empty stomachs. We found 15 prey types in *E. parvus* diet (considering all insect larvae together; Table 1). The most frequent items were Hymenoptera-Formicidae (41.9% of the stomachs analyzed), Acari (21%), Araneae (19.3%), and Isopoda (11.7%). Ants and mites were the most numerous (49.5% and 13.3% of the total items found, respectively) prey types consumed. In terms of volume, the most representative items were Araneae (62.4 mm^3, 16.4%), Isopoda (61.9 mm^3, 16.2%) and Formicidae (45.6 mm^3, 12.0%). Plant remains were found in only four (6.4%) of the frogs analyzed, being usually small fragments of dead leaves probably ingested incidentally during the capture of prey. As a result, we did not include these items in the diet estimation.

The relationship between jaw width and mean volume of the five largest items ($R^2 = 0.30$, $F_{1,45} = 19.44$) and mean length of the five largest prey items ($R^2 = 0.36$, $F_{1,45} = 25.14$) were both statistically significant ($P < 0.001$; Fig. 1).

At Ilha Grande, *E. parvus* fed exclusively on arthropods. Ants were the most frequent and numerous prey item and, together with mites, spiders, and isopods they seem to constitute important prey groups to maintain the *E. parvus* population at the studied area. Ants are common in the leaf litter arthropod community sampled in the same area (M. B. Vecchi, pers. comm.). Ant eating is known for several *Eleutherodactylus* species, in different frequencies (Duellman 1978; Ovaska 1991; Stewart and Woolbright 1996; Toft 1980b; 1981).

Spiders and isopods were the largest items found in the stomachs, and these prey types are relatively non-chitinous in relation to their body size, non-toxic, mobile, and cryptic (Toft 1980b) and, according to the categories created by Toft (1980b), *E. parvus* should be considered a "non-ant specialist" species, because of the ingestion of these prey types in large frequencies. But we have no data on selectivity of prey by *E. parvus*, and because ants were the most frequent item in the diet, we are not able to fit this frog into one of Toft's categories.

Our data show that the SUL of *E. parvus* affects the size of the ingested prey (by prey volume and length). This result is expected for predators which do not chew their prey and are further limited by gape size (Lima and Moreira 1993; Van Sluys et al. 2001). Prey size increases with increasing frog body size, a trend also found for *E. coqui* and other anurans (Woolbright and Stewart 1987 cited in Ovaska 1991).

Considering the broad range of prey types, we conclude that *E. parvus* is a carnivorous predator in the leaf-litter microhabitat, its diet being composed exclusively by arthropods.

Acknowledgments.—This study is a portion of the results of the "Ecology, Conservation and Management of Southeastern Brazilian Ecosystems Program" and of the Southeastern Brazilian Vertebrate Ecology Project (Vertebrate Ecology Laboratory), both of the Depto. de Ecologia, Instituto de Biologia Roberto Alcântara Gomes, Universidade do Estado

do Rio de Janeiro. We thank the Coordination of the CEADS/UERJ and the Direction of Campi Regionais for local support and for making many facilities available. We also thank the Sub-Reitoria de Pós-Graduação e Pesquisa (SR-2/UERJ) and the former Sub-Reitor R. Guimarães for Institutional support and many facilities along the study. We thank H. G. Bergallo, D. Vrcibradic and M. A. S. Alves for their help in collecting frogs. We also thank M. B. Vecchi, L. Boquimpani-Freitas, F. H. Hatano and A. F. N. Freitas for their laboratory assistance. D. Vrcibradic read the original manuscript and offered helpful suggestions. This study was partially supported by grants from FAPERJ (26/172.383/00) CNPq (477 981/03-8). CFDR (Process Nº 307653/03-0) and MVS (Process Nº 302405/02-0) received Research Grants from the Conselho Nacional do Desenvolvimento Científico e Tecnológico (CNPq) and RVM received a graduate grant from Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ). During field work, RVM received undergraduate fellowships from CNPq and UERJ.

Natural History and Reproductive Behavior of *Nyctibatrachus cf. humayuni* (Anura: Ranidae)

KRUSHNAMEGH KUNTE*

Life Research Foundation, 1000/6-C, Pranav
Navi Peth, Pune 411030, India

The genus *Nyctibatrachus* Boulenger 1882 (family Ranidae) is endemic to the Western Ghats mountain chain of southwestern India, and comprises ten described species (Dutta 1997; Krishnamurthi et al. 2001). Species of *Nyctibatrachus* are found mainly in the rocky streams of montane and submontane evergreen and semi-evergreen forests. Apart from taxonomic descriptions and distributional records there is little information on these frogs and the observations reported herein are the first accounts of natural history and reproductive behavior of any *Nyctibatrachus* species.

I observed *Nyctibatrachus cf. humayuni* at various localities (elevational range 75–300 m) in the states of Goa and Karnataka in southern India, but mainly between Castle Rock and Dudhsagar (15.41°N, 74.33°E to 15.35°N, 74.3°E). Annual precipitation here is 3000–5000 mm. The main rainy season, resulting from a southwest monsoon, is from June to September. There are a few showers from a northeast monsoon in November and early December. The forest is semi-evergreen and evergreen, ca. 15–25 m tall, and undergrowth is thick. Numerous small streams cut through these forests, often forming steep rocky watercourses with abundant overhanging vegetation. These streams are the natural habitat of this frog and the overhanging vegetation provides oviposition sites.

My observations span monsoonal seasons over a five-year period (1997–2001). During my study I captured individual frogs on first sighting, recorded snout–vent lengths (SVLs) to the nearest 0.1 mm using a vernier caliper, and noted sex. I marked each individual by fixing a narrow, uniquely colored strip of balloon around the waist and released each frog at point of capture. Marking with balloon strips did not seem to harm the frogs or disrupt their activities. Marked frogs neither abandoned their calling posts nor stopped vocalizing. Moreover, they seemed to attract females and fertilize eggs just as efficiently as they did before marking. I measured mating success of males (Fig. 3) over a period of 8 nights in the years 1998 and 2001 (total 16 nights). I considered only neighboring males to make direct comparisons meaningful, and excluded very old egg-clutches from male territories for this analysis because they could have been fertilized by other males in cases of territory takeovers. During the nights of direct observations I counted new clutches fertilized by territorial males. Therefore,

although my measurements might be slight underestimates, they are corrected for temporal (number of days the males were observed) and spatial (micro-spatial variation in mating success) biases.

I collected all the marked frogs from 1998 and 1999 and preserved them in 10% formaldehyde solution when field observations were terminated. Hemant Ghate in the Department of Zoology, Modern College, Pune, is currently studying the taxonomic status of *N. cf. humayuni*. Morphometric measurements and certain behavioral details pertaining to individual frogs observed in the field are described elsewhere (Kunte 2001).

Sexual dimorphism.—Sexes in *N. cf. humayuni* are subtly dimorphic. SVL of calling adult males was 42.08 ± 3.24 mm (range 32–47 mm; N = 29) and that of adult females, 41.42 ± 2.61 mm (range 37–45.5 mm; N = 15). Males lack the nuptial pads which are present in many male anurans; I attribute their absence to the lack of amplexus. Only adult males had femoral glands colored pale orange to bright orange or pink. Males also had larger toe-discs as compared to females. Toe-discs are known to offer firm hold on smooth substrates, such as leaves. Therefore, larger toe-discs of males probably help them hold onto smooth leaves during the extended vocalization periods.

Vocalization.—Breeding activity commenced by the end of May or early June at the onset of the southwest monsoon and continued until mid-September. Thereafter, occasional rains and the northeast monsoon triggered short spurts of breeding. Males vocalized throughout the breeding season. The vocalizations began at dusk. The call was a soft and melodious, prolonged note—OORRsss—with an occasional faint "OA" preceding the call. Males vocalized with an average frequency of 6 calls/min. They perched at a height of up to 1 m on leaves overhanging flowing water of forest streams. When overhanging vegetation was absent they positioned themselves on slanting moss-free faces of wet rocks flanking the streams.

Vocalization continued until ca. 2130–2200 h. Then some of the males stopped vocalizing while others vocalized less frequently or occasionally. The males foraged afterwards, as evidenced by gut contents of males that had been vocalizing for as long as 8 nights. After foraging, the males took refuge before dawn in crevices or under rocks.

Territoriality.—Males maintained large territories in which oviposition took place. An individual territory consisted of suitable calling posts on over-hanging vegetation or moss-free rock and the underlying portion of the stream. The average inter-male (between calling posts) distance was 7.92 ± 3.28 m (N = 32), with a mode at 5 m (N = 11). A minimum distance of 5 m was always maintained between two calling posts. The calling posts later served as oviposition sites.

Territories were exclusive, in which only one calling male reigned. In two instances new males replaced the territorial males; in both occurrences larger males seemed to have dominated (Kunte 2001). Adult males not engaged in reproductive activities were never seen close to territories of calling males. It is possible that these males have short non-reproductive spells of a few days or weeks during which they forage away from the territorial males, gain weight or mass and later replace territorial males. My search for silent satellite males, which associate themselves with calling territorial male frogs and intercept gravid females (Arak 1988; Bourne 1993; Howard 1978), did not reveal any in *N. cf. humayuni*.

Egg-laying.—I observed seven complete egg-laying sequences. The following was a standard egg-laying process. Males vocalized usually from leaves ca. 10–100 cm above flowing water 2–30 cm deep. Observations on marked females revealed that females foraged in the territories of several males, which probably provided them time and opportunity to rank males and their territories. When a female was ready to lay a clutch of eggs she climbed to the spot from where a chosen male had been vocalizing. The male vocalized with slightly higher frequency of calling when the female approached. The male moved a few centimeters away from its calling post when the female approached but continued vocalizing. The female reached the exact original calling post and deposited eggs. If the female laid part of her clutch in another spot, it was always the second spot to which the calling male had shifted upon the female's arrival. Thus, the male, rather than the female, determined oviposition sites, with the female laying eggs exactly at the spot from where the male had been calling. There was no amplexus or any physical contact between the sexes (however, in another egg-laying sequence I observed 'pseudo-amplexus.' This preceded oviposition by 5 min and therefore did not serve the pur-

FIG. 1. This figure shows oviposition behavior and lack of amplexus in *Nyctibatrachus cf. humayuni*. The female to the right was laying eggs without the male being in amplexus while another gravid female waited beside it (note the bulging abdomen). The male on the lower part of the leaf was waiting for the female to finish oviposition, it fertilized the eggs after the female left. Note the old clutch at an advanced stage of development beside the male. Egg-clutches fertilized by a male are often clumped. Also note much larger toe-discs and thicker digits of male as compared to the females.

pose of fertilization [Kunte 2001]). Vocal communication on the part of the female was not perceptible. After laying its clutch, the female immediately entered the water and moved away. The male then stopped vocalizing and positioned itself over the eggs to enable fertilization. For the same purpose, sometimes the male also moved a little over the clutch, seemingly ensuring that all the eggs received sperm. When it had released semen the male resumed vocalization within a few minutes from a different post only a few centimeters away from the freshly laid eggs, often on the same leaf. On successive nights the male continued vocalizing from the new post until another female visited. Thus, eggs laid by different females but fertilized by the same male tended to be spatially clumped on the same leaf or on neighboring leaves on the same branch (Fig. 1).

Clutch size, fertilization success, hatching success, and multiple clutching.—I observed a total of 1937 eggs comprising 85 clutches. Egg diameter at the time of oviposition was 2.5–3 mm (N = 15, from 3 clutches). Clutch size ranged from 10 to 55 eggs, with a median of 21 and mean of 22.79 ± 8.84 eggs (Fig. 2). Fertilization success in all 85 clutches was 100%. The length of the egg stage in the developmental process was approx. 12–15 days. When tadpoles were ready to hatch they wriggled violently in the egg-jelly, which burst, releasing the tadpoles. The ejected tadpoles fell in the flowing water below where they fed at the bottom close to the banks. I did not observe any pre-hatching mortality; tadpoles from over 700 eggs (ca. 30 observed clutches) ejected out of the jelly capsules successfully.

Six females were dissected for ovarian examination. Females preserved 1–4 days post-oviposition had a new batch of eggs developing in their ovaries; these would have matured in 10–15 days. Females that were caught close to calling males had a batch of eggs ready to be laid and yet another batch developing, which would have been ready after 10–15 days. It is evident, therefore, that females lay a minimum of two clutches. Judging from the prolonged breeding season of this species and assuming that eggs are produced throughout the breeding season, females can potentially produce as many as 6 egg-clutches per breeding season.

Male mating success and sexual dimorphism.—Most of the calling males were successful in obtaining at least one but typically multiple matings (Fig. 3). As a consequence, variance in reproductive success of male *Nyctibatrachus* might not be as high as in those species in which a few males monopolize all matings (Cherry 1993; Table 3.3 in Duellman and Trueb 1986). Also, many individual females possibly laid multiple clutches in a season. Hence, it would be interesting to work out reproductive success of both sexes in this species, which will perhaps be comparable. Thus, low variance in reproductive success of males and comparable fitness of both sexes may be the two reasons why sexes are similar in size, and only subtly dimorphic, in *Nyctibatrachus*.

The reproductive biology of *N. cf. humayuni* has remarkable features. Of particular interest is the lack of amplexus. In anurans amplexus has been considered an adaptive behavior that facilitates juxtaposition of cloacae of male and female during oviposition, which is important for success in external fertilization (Duellman and Trueb 1986). The total lack of amplexus has so far been reported only in Central and South American arrow-poison frogs (family Dendrobatidae) (Crump 1972; Limerick 1980) and Darwin's frog (*Rhinoderma darwinii*) (Busse 1991). These frogs

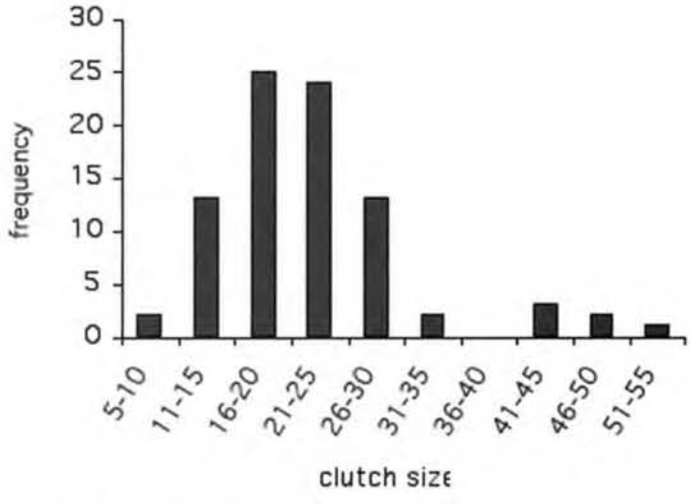

FIG. 2. Clutch size in *Nyctibatrachus cf. humayuni.*

have a different set of reproductive behaviors and life history traits as compared to *N. cf. humayuni.* For example, dendrobatids usually lay less than half a dozen eggs (some species, just one), and exhibit parental care unlike *Nyctibatrachus*. Darwin's frogs also have parental care. Interestingly, despite the evolutionary advantages usually attributed to the presence of amplexus, *Nyctibatrachus* has achieved 100% fertilization success in its total absence. Loose, abbreviated, or otherwise crude forms of amplexus are reported in many anurans, e.g., in *Discoglossus* (Knoepffler 1962) and Madagascan *Mantidactylus* (Blommers-Schlösser 1975) and *Mantella* (Arnoult 1966; Heying 2001). Therefore, *Nyctibatrachus* is only the third anuran group in which amplexus is totally absent and the first record of such a frog from the Old World.

Another notable feature of the breeding biology of this species is the nature of oviposition sites and clutch sizes. *Nyctibatrachus* is among the rare anurans that deposit eggs outside water—on ground or vegetation but not in a foam-nest, and whose larvae drop into water when they hatch (other examples in Duellman and Trueb 1986). Many of these species lay small clutches of large eggs. Central and South American glass frogs (family Centrolenidae) have similar breeding habits to *Nyctibatrachus*,

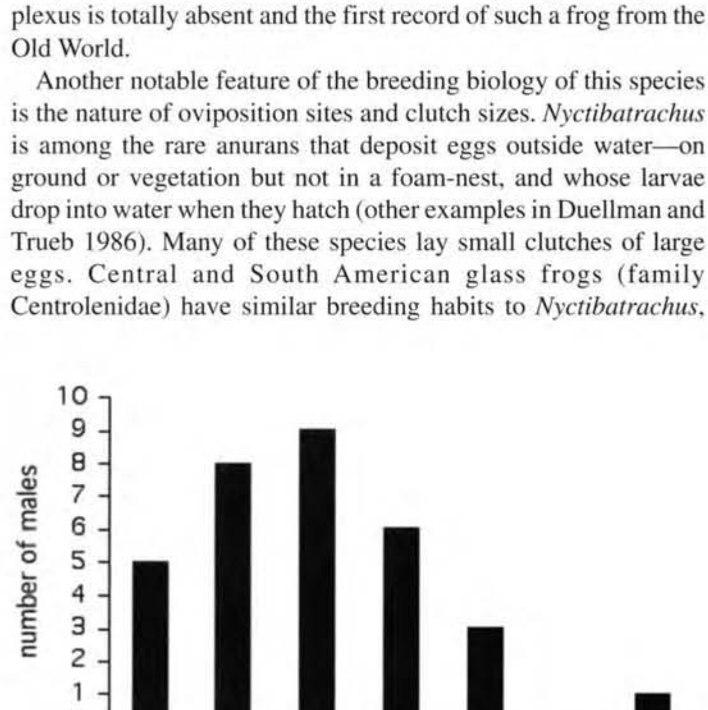

FIG. 3. Mating success of male *Nyctibatrachus*. Most males get at least one, typically multiple, matings.

although they have amplexus and parental care (Mc Diarmid 1978). *Phyllomedusa* and related genera (Kenny 1966; Vaira 2001) also have similar eggs, clutch sizes, and oviposition sites. It would be interesting to compare reproductive behaviors and mating success of these frogs.

Acknowledgements.—I thank the Indian Herpetological Society (Pune), Centre for Ecological Sciences, and Indian Academy of Sciences (Bangalore) for funding field work. Aadish Dani, Shantanu Goel, Ankush Paryekas, and Sanjay Sondhi provided field assistance. Hemant Ghate dissected the frogs and investigated their reproductive status. Sayantan Biswas, Ashok Captain, Indraneil Das, Hemant Ghate, Vivek Gour-Broome, Shomen Mukherjee, Samraat Pawar, Juan Carlos Santos, Anindya Sinha, and Karthik Vasudevan gave useful information and read various drafts of this paper. Finally, Martha Crump provided critical comments as reviewer of the manuscript.

The Origins of the Anuran Interdigital Webbing Formula

ROSS D. MacCULLOCH
Centre for Biodiversity and Conservation Biology, Royal Ontario Museum
100 Queen's Park, Toronto, Ontario M5S 2C6, Canada
e-mail: rossm@rom.on.ca

An established and useful part of anuran descriptions is the webbing formula, which expresses the extent of the webbing between fingers and toes in a standardized manner. This formula enumerates those phalanges which are free of webbing, rather than those which are webbed; this obviates the problem of whether to include metacarpals and metatarsals in the count of "phalanges." The development of the formula for expressing interdigital webbing has an interesting history, and its origin has often gone unacknowledged.

Many early authors used descriptors such as "¼ webbed" or "½ webbed." The major drawback to this system is that it requires a subjective assessment of the extent of the webbing, there being no clear, objective criteria upon which the fractions are based.

Edwards (1974) developed a formula which enumerated the number of phalanges which are covered by webbing. This system was used to describe webbing in *Colostethus* by La Marca (1985, 1997).

Loveridge seems to have been the first to quantify the extent of the webbing by enumerating the phalanges that are free of webbing. Loveridge (1933, p. 90) described the toes of *Glauertia* [*Uperoleia*] *russelli* as: "...strongly webbed, at most a single joint free with the exception of the fourth which has three joints free...." This method was elaborated upon in later work; "...of its toes only the first has a single joint free, the second, third and fifth are webbed to the disks on at least one side, the fourth has one and a half (right) to 2 (left) joints free of web" (Loveridge 1941, p. 129). Loveridge used "joint" as the equivalent of phalanx. Although Loveridge's descriptive method is useful and objectively quantifiable, no notation formula was established.

Rivero also described webbing using the number of free phalanges, but in his method "...the fingers and toes are placed close together and the extension of the webbing is determined by considering the middle, not the margins, of the membrane" (Rivero 1961, p. 15). Although Rivero stated that "Loveridge's system of measuring the amount of webbing by giving the number of free phalanges has been adopted here...." (*ibid*, p. 15), Rivero's system departs from Loveridge's in that Loveridge measured webbing by counting the number of free phalanges ("joints") to the point of contact between web and digit, while Rivero counted free phalanges to a point corresponding to the deepest emargination of the webbing between adpressed digits. An example of Rivero's notation is "...toes taken in order from first to fifth exhibit the following phalanges free of web: 1⅔, 1, 1½, 2½ to 3, 1 to 1¼;..." (*ibid*, p. 106). Although it is not explicitly stated, Rivero seems to offer a range of variation in the extent of the webbing, but makes no distinction between the inner and outer sides of the toes.

Savage and Heyer (1967) established a formula similar to that

which is widely used today. The formula is based on a phalanx numbering system in which "...A notation of 0 indicates that the web reaches the base of the finger or toe disk, 1 indicates that the web reaches the base of the terminal phalanx" (*ibid*, p. 116). Savage and Heyer clearly stated that "The position of the web was determined by the point of union with the digit, excluding narrow fleshy fringes on the digits..." The use of "+" and "–" in superscript position, representing the proximal and distal ends of the subarticular tubercles respectively, was also premiered in this paper. The following was used as an example of the formula (*ibid*, p. 116): "I 2–2,5 II 2^-–3^- III 2^+–2^- IV 3–3^- V." The same technique was used in subsequent papers (e.g., Savage 1968; Savage and Heyer 1969), although fractions rather than decimals were used to indicate the number of free phalanges (i.e., 2½ rather than 2,5).

Myers and Duellman (1982) modified this notation somewhat, by combining Savage and Heyer's "0" and "1" notations into a single "1" representing the terminal phalanx, inclusive of the disc. The "0" was reserved "...for those frogs in which the webbing extends to the very tip of a digit...." (*ibid*, p. 6, footnote). This formula was further refined by Savage and Heyer (1997). Myers and Duellman also modified the Savage and Heyer formula by using boldface for the Roman numerals. Myers and Duellman also pointed out that "....there is an element of subjectivity. Determining degree of webbing sometimes amounts to assigning a point on a smooth curve, as when a deeply emarginate web curves up to join a fringed digit near its tip." (*ibid*, p. 6, footnote). When modern publications credit the technique of webbing notation formula, it is Myers and Duellman (1982) that is typically cited.

However, a method to describe webbing by enumerating the number of phalanges which are free of webbing had been used previously by Guibé and Lamotte (1955a, 1957). In these publications the notation was not written on a single line of text, but as shown below (from Guibé and Lamotte 1957, p. 959):

I	II		III		IV		V
	int.	ext.	int.	ext.	int.	ext.	
2	2½	1	3	1	2	2	1

The notation is accompanied by a drawing of the foot, showing that the system of numbering phalanges is the same as that used by Myers and Duellman (1982). The notation is accompanied by an explanation in the text, e.g.: "The webbing....leaves the following numbers of phalanges free on each toe..." (Guibé and Lamotte 1957, p. 959).

There is no evidence that Guibé and/or Lamotte used the notation before 1955. In earlier papers (e.g., Guibé and Lamotte 1953) webbing was described in the text by listing the numbers of free phalanges on each toe in a fashion similar to that employed by Loveridge (1941).

The webbing notation was used inconsistently in subsequent publications by Guibé and/or Lamotte. For example, Guibé (1960), Guibé and Lamotte (1955b), and Lamotte (1967) used the notation, but Guibé (1973) and Guibé and Lamotte (1958, 1960, 1961) provided only a verbal description of the extent of the webbing, with illustrations. One interesting modification was the adaptation of the notation to compare the webbing of two or more taxa (Guibé and Lamotte 1955b, 1957; Lamotte 1967).

Lescure (1975), in his description of *Colostethus degranvillei*, used a formula based on Guibé and Lamotte (1957). Lescure (1975) refined Guibé and Lamotte's notational system by condensing the information to a single line of text; "....I 1–2 II 1½–3 III 2–4 IV 4–2½ V...." (*ibid*, p. 414). Lescure's use of the formula is very similar to the Myers and Duellman (1982) modification of Savage and Heyer (1967), the only difference being that the Roman numerals are not in boldface. Lescure (1975, p. 414) describes the webbing formula as: "... counting free phalanges, including the disc-bearing [phalanx], on each side of the digits [which are] numbered in Roman numerals...." As well as citing Guibé and Lamotte (1957) as the source of this technique, Lescure also states that the method is "...preferable to that of Rivero (1961) which I have been using previously. Toes [of specimens], which are often adpressed and rigid, prevent the accurate determination of the height of the middle of the webbing membrane." (p. 414, footnote). Lescure also used the same formula in subsequent publications (e.g., Lescure 1981). At no time did Lescure or Guibé and Lamotte use the "+" and "–" modifiers to indicate the point of contact relative to the position of the subarticular tubercles; this usage must be attributed to Savage and Heyer (1967).

Guibé and Lamotte have received little credit for the development of their notational system. This might be because the seminal paper was published in a journal which is not widely available. Furthermore, because even its originators did not utilize it consistently, it is perhaps not surprising that the scheme devised by Guibé and Lamotte was not widely accepted.

The system to describe interdigital webbing was devised as a notation by Guibé and Lamotte (1955a) and as a formula by Savage and Heyer (1967), independently. The former was refined by Lescure (1975), the latter by Myers and Duellman (1982). Whereas the work of Savage and Heyer (1967), as refined by Myers and Duellman (1982) and Savage and Heyer (1997), has been widely used and cited, Guibé and Lamotte's work suffered from inconsistent usage. Nonetheless, since Guibé and Lamotte (1955a) is the earlier date, this publication may be credited as the first use of a notation which enumerates free phalanges on either side of each toe.

Acknowledgments.—T. Frétey kindly provided a copy of Guibé and Lamotte (1957). W. R. Heyer, G. Köhler, and an anonymous reviewer provided comments on an earlier version. This is contribution 268 of the Centre for Biodiversity and Conservation Biology, ROM.

Drift fences used with pitfall and/or funnel traps are a standard field technique used to sample amphibian and reptile communities (Campbell and Christman 1982; Corn 1994). Drift-fence sampling is effective in collecting large numbers of animals in a relatively short period of time (Gibbons and Semlitsch 1981; Rodda et al. 2001).

A variety of materials have been used for drift fences, but aluminum flashing is the best choice for long-term studies because of its durability (Gibbons and Semlitsch 1981). Aluminum flashing is expensive and often is not feasible for short-term inventory studies that do not have a large budget. Polyurethane has been used for drift fences to study amphibian reproductive biology by encircling breeding ponds (Douglas 1979).

Enge (1997) proposed the use of silt fencing as an alternative. Silt fencing is a woven polypropylene material that is about one-third the cost of aluminum flashing and is particularly desirable when sampling hydric environments. Silt fencing can also be used in terrestrial habitats. Zug et al. (2001) report the use of silt fencing for monitoring amphibian and reptile populations at a tropical site in Myanmar and one of us (JHM) has used silt fencing for short-term sampling (2–3 months) of herpetofaunal communities in the Edwards Plateau of Texas.

In the tropics, where "common species are rare and rare species are common" (Forsyth and Miyata 1984), drift-fence sampling might be an effective technique to sample amphibian and reptile species, yet little data are available (but see Brown et al. 1996; Zug et al. 2001). In the United States aluminum flashing and silt fencing are both readily available, but elsewhere, particularly in the tropics, this may not be the case. Furthermore, the cost of importing aluminum flashing or silt fencing via air carrier might be exceedingly high because of the weight of the material. Another problem with drift fencing in wet tropical forest is the high rate of treefalls (Brokaw 1996). Treefalls can destroy aluminum or silt-based drift fencing and require considerable effort to repair (pers. obs.). Therefore, for drift fence sampling to be convenient and feasible in a tropical forest, the material must be available, affordable, and the drift fence should be repairable in a modest amount of time. As an alternative to aluminum flashing and silt fencing, we herein describe the use of polystyrene to construct drift fences

pus novemcinctus) is known to consume *V. stiatula* (Breece and Dusi 1995. *In* Montgomery [ed.], The Evolution and Ecology of Armadillos, Sloths, and Vermilinguas. Smithsonian Inst. Press, Washington. 451 pp.). The only record concerning avian predation on *V. striatula* that I am aware of involves the Eastern Screech Owl (*Otus asio*; Gehlbach and Baldridge 1987. Oecologia 71:560–563).

On 2 December 2002 at 1130 h, air temperature 13°C, I observed a Northern Mockingbird (*Mimus polyglottos*) holding a *V. striatula* in its beak. The event took place in the yard of a rural farmhouse 4.6 km (air) N of Waverly, in Chambers Co., Alabama, USA. The bird was grasping the snake by the tail, immediately posterior to the vent. Upon my approach, the bird flew from the stone terrace where it was perched and sought refuge behind dense shrubbery. When I saw the bird again, it had dropped the snake at its feet and took flight when I came within 4 m of it. At this point I collected the snake, which was entirely limp with the exception of an occasional twitch of its head. The subcaudal portion of the snake was bloody, and there was a single wound at mid-body. These injuries were presumably inflicted by the bird's beak. Additionally, I noted a slight abrasion on the snake's head and assume that the bird had subdued its prey by thrashing it against the stonework.

The snake (AUM 35662) is female, 197 mm SVL, 225 mm TL, and 3.4 g. The Northern Mockingbird is characterized as omnivorous, and is known to take *Anolis* lizards (Derrickson and Breitwisch 1992 *In* Poole et al. [eds.], The Birds of North America, No. 7, Northern Mockingbird (*Mimus polyglottos*), pp. 1–26. American Ornithological Union, Washington, D.C. and the Academy of Natural Sciences, Philadelphia, Pennsylvania). I believe this to be the first record of ophiophagy by *M. polyglottos*.

Thanks to S. M. Boback, and C. Guyer for constructive comments.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother 2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. SSAR Herpetol. Circ. 29:1–82, available online at <http://herplit.com/SSAR/circulars/HC29/Crother.html>; for Mexico as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*. Herpetol. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state or province names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary) to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extensions unless a thorough literature review has been completed.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canadian records only); **Jerry D. Johnson** (Mexico and Central America, including the Caribbean islands); **Hidetoshi Ota** (all Old World records); or **Gustavo J. Scrocchi** (South American records). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Schmitz, A., and T. Ziegler. 2003. Geographic distribution. *Sphenomorphus rufocaudatus*. Herpetol. Rev. 34:385.

CAUDATA

AMBYSTOMA TIGRINUM MELANOSTICTUM (Blotched Tiger Salamander). USA: SOUTH DAKOTA: ROBERTS CO.: wetland adjacent to South Dakota Hwy 25, ca. 1.6 km W Hammer (45°50' 55.6"N; 97°02' 21.3"W). 8 September 2003. Laurs Bryan Williams. Verified by Stanlee Miller. Campbell Museum, Clemson University (CUSC 2167). County record. Previously reported in adjacent Marshall, Day, and Grant counties (Fischer et al. 1999. A Field Guide to South Dakota Amphibians. South Dakota Agric. Exp. Sta. Bull. 733. South Dakota State University, Brookings. 52 pp.).

Submitted by **LAURS BRYAN WILLIAMS** and **STEVEN G. PLATT**, Department of Math and Science, Oglala Lakota College, P.O. Box 490, Kyle, South Dakota, 57752-0490, USA.

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). USA: TENNESSEE: COFFEE CO: seep flowing into Davidson Branch, ca. 1.1 km SW of Ward Chapel, ca. 250 m N of Riley Creek Rd (35°28'02.5"N, 86°11'17.6"W). 19 April 2003. Matthew L. Niemiller. Verified by Addison Wynn. Smithsonian National Museum of Natural History, USNM-FS 186610. Larva found under rock within seep. Tissue sample collected; salamander was photographed and released. First record from Coffee County and southernmost record on the Eastern Highland Rim (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.). Tissue sample collected under authorization of the Tennessee Wildlife Resources Agency (permit no. 1724-03B).

Submitted by **MATTHEW L. NIEMILLER**, Middle Tennessee State University, Murfreesboro, Tennessee, 37130, USA; e-mail: mln2a@mtsu.edu.

ANURA

APARASPHENODON VENEZOLANUS (Venezuela Casque-headed Frog). BRAZIL: AMAZONAS STATE: Campina from Jaú National Park (01°54'45"S 61°35'20"W). 19 March 2000. S. Neckel-Oliveira and M. Gordo. Herpetological collection from Instituto Nacional de Pesquisas da Amazônia, Manaus (INPA - H 10939). Verified by J. Lynch. One male found at 2200 h at edges of ponds in campina habitat—characterized by sandy soil that is seasonally flooded by rainfall. First country record. Species previously known from southwestern Amazonian Venezuela and adjacent Colombia; present record extends known distribution ca. 900 km airline from Guaínia, Colombia (Frost 2003. Amphibian Species of the World. Version 2.21/2003).

Submitted by **SELVINO NECKEL-OLIVEIRA**, Instituto Nacional de Pesquisas da Amazônia, CP 478, 69011-970, Manaus, Am, Brazil (e-mail: neckel@inpa.gov.br), and **MARCELO GORDO**, Universidade Federal do Amazonas, Manaus, Am. Brazil; e-mail: mgordo@ufam.edu.br.

BUFO AMERICANUS (American Toad). USA: GEORGIA: FLOYD CO.: Dozier Creek. 21 July 2003. Bradley L. Johnston. GMNH 49220. Verified by John Jensen. New county record (Williamson and Moulis. 1994. Distribution of Amphibians and Reptiles in Georgia. Savannah Sci. Mus. Spec. Publ. No. 3, 712 pp.).

Submitted by **BRADLEY L. JOHNSTON**, 341 Bells Ferry Road, Rome, Georgia 30161, USA.

BUFO SPECIOSUS (Texas Toad). USA TEXAS: STERLING CO: AOR ca. 10 road km E of Sterling City, Hwy 87. 16 April 2001. James A. Holm and Kathryn E. Perez. Verified by J. Kelly McCoy. Angelo State University Natural History Collection (ASNHC 13581). First county record (Dixon 2000. Amphibians and Reptiles of Texas. Second Ed. Univ. of Texas A&M Press, viii + 421 pp.).

Submitted by **JAMES A. HOLM**, 18719 Woodglen Shadows Drive, Humble, Texas 77346, USA; e-mail: jaz_holm@hotmail.com.

ELEUTHERODACTYLUS BIPORCATUS (Puerto Cabello Robber Frog). VENEZUELA: ESTADO FALCON: Municipio Unión, Estación de Guardaparques, Parque Nacional Cueva Quebrada del Toro. August 2002. R. A. Rivero. Museo de la Estación Biológica de Rancho Grande (EBRG 4826), Ministerio del Ambiente y de los Recursos Naturales, Maracay. Verified by A. Arends. First state record (Mijares-Urrutia and Arends 2000. Smithson. Herpetol. Infor. Serv. 123:1–30). This record represents an extension of ca. 135 km NW from its nearest known locality in Coastal Range, northern Venezuela (Frost, 2002. Amphibian Species of the World [online]. Ver. 2.21. American Museum of Natural History, New York; Manzanilla et al. 1995. Acta Cient. Venez. 46:1–15).

ELEUTHERODACTYLUS DIMIDIATUS (Ranita de Antifaz). CUBA: MATANZAS: CIÉNAGA DE ZAPATA: ca. 5 km from Buenaventura, 100 m NE of the road to Santo Tomás (81°15'57.24"N, 22°19'27.48"W). May 1997. A. Rodríguez. Instituto de Ecología y Sistemática, Colección Zoológica de la Academia de Ciencias de Cuba (CZACC 14 3776). Verified by L. V. Moreno. CUBA: Isla de la Juventud: Los Indios River, ca. 800 m to the NE of the "Los Indios" Ecological Station (82°59'30.48"N, 21°4.68"W). 11 August 1999. A. Rodríguez and R. Alonso. CZACC 145600. Verified by L. V. Moreno. First record of this species from "Llanura de Zapata" and "Isla de la Juventud-Archipiélago de los Canarreos," two biogeographic regions from which it was considered absent (Hedges 1999, *In* Duellman [ed.], Patterns of Distribution of Amphibians, A Global Perspective, pp. 211–254. Johns Hopkins University Press, Baltimore and London).

Submitted by **ARIEL RODRÍGUEZ** and **ROBERTO ALONSO**, Instituto de Ecología y Sistemática, Carr. de Varona, Km 3, Capdevila, Boyeros. AP 8029, CP 10800, Ciudad de la Habana, Cuba; e-mail: zoologia.ies@ama.cu.

ELEUTHERODACTYLUS EILEENAE (Colín). CUBA: MATANZAS: CIÉNAGA DE ZAPATA: ca. 5 km from Buenaventura, 100 m NE from the road to Santo Tomás (81°15'57.24"N, 22°19'27.48"W). May 1997. A. Rodríguez. Instituto de Ecología y Sistemática, Colección Zoológica de la Academia de Ciencias de Cuba (CZACC 14 3415). Verified by L. V. Moreno. First record of this species in the "Llanura de Zapata," a biogeographic region where it was previously considered absent (Hedges 1999, *In* Duellman [ed.], Patterns of Distribution of Amphibians, A Global Perspective, pp. 211–254. Johns Hopkins University Press, Baltimore and London).

Submitted by **ARIEL RODRÍGUEZ** and **ROBERTO ALONSO**, Instituto de Ecología y Sistemática, Carr. de Varona, Km 3, Capdevila, Boyeros. AP 8029, CP 10800, Ciudad de la Habana, Cuba; e-mail: zoologia.ies@ama.cu.

ELEUTHERODACTYLUS LIBRARIUS (NCN). ECUADOR: PROVINCIA NAPO: CANTÓN TENA: Serena village, S side upper Napo River (01°05'43"S, 77°55'28"W), 560 m elev., 1 May 2003. K. R. Elmer and T. Sugahara. Museo de Zoología de la Pontificia Universidad Católica del Ecuador, Quito (QCAZ 25851: adult female, SVL 24.1 mm; QCAZ 25852: adult female, SVL 23.8 mm; SVL 22.9 mm; in an agricultural area surrounded by secondary forest, perched on vegetation < 1 m above ground). PROVINCIA ORELLANA: Yasuní River, south side, ca. 220 m elev., November 1993. F. Campos. (QCAZ 7356: juvenile, SVL 14.7 mm; QCAZ 7357: juvenile female, SVL 19.9 mm). CANTÓN COCA: ca. 5 km S of Dayuma village (00°41'44"S, 76°43'50"W), 267 m elev., 19 March 2003. K. R. Elmer, S. Padilla, and P. Menéndez-Guerrero. (QCAZ 25589: adult female, SVL 24.6 mm; in a coffee plantation with primary forest behind and a road on one side, perched on vegetation < 1 m above ground). PROVINCIA MORONA SANTIAGO: 600–1200 m elev., September 1997. J. Izquierdo. (QCAZ 12209: adult male, SVL 19.2 mm; QCAZ 12210: SVL 22.2 mm). All verified by Luis A. Coloma and Gregory O. Vigle. This species was previously known only from its type locality, the Jatun Sacha Biological Reserve, Napo, Ecuador (01°04'S, 77°36'W) (Flores and Vigle 1994. J. Herpetol. 28:416–424). These

new records represent a substantial range extension for the species: Serena is 34 km W, Dayuma is 107 km ENE, Morona Santiago is a minimum of 90 km, maximum of ca. 210 km S, and Yasuní River is 120–150 km E (all kms are straight-line) from the Jatun Sacha Reserve.

Submitted by **KATHRYN R. ELMER**, Department of Biology, Queen's University, Kingston, Ontario, K7L 3N6, Canada; e-mail: ElmerK@biology.queensu.ca.

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: FLORIDA: LEVY CO: Seahorse Key, upland hammock and beaches. 2 June 2001. Harvey B. Lillywhite and Coleman M. Sheehy III. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida, Gainesville (UF 123955). This is a new record for Seahorse Key as well as the adjacent collective islands of the Cedar Keys. Several specimens were found active in leaf litter and in pitfall traps. Moreover, these frogs have been observed or heard calling on at least six occasions since the original discovery, all in connection with recent rainfall. Seahorse Key has no permanent source of fresh water, so this record affirms the success of this species in colonizing offshore islands that might be hostile environments for other amphibians. The presence of *E. planirostris* is possible because of its terrestrial mode of direct reproduction. It appears the frogs are quite common in leaf litter within the insular hammock and probably occur on other islands within the Cedar Keys as well. Elsewhere, in the Florida Keys and Caribbean, this species has been reported beneath stones and other objects on beaches at the very edge of the sea (Neill 1958. Bull. Mar. Sci. Gulf Caribbean 8[1]:1–97). *Eleutherodactylus planirostris* was not known from Seahorse Key or adjacent islands during the studies of Charles Wharton (1958. The Ecology of the Cottonmouths *Agkistrodon piscivorus piscivorus* Lacepede of Sea Horse Key, Florida. PhD dissertation, University of Florida, Gainesville). As at other sites (Johnson et al. 2003. Herpetol. Rev. 34:161–162), this species appears to have colonized parts of north Florida during the relatively recent past.

Submitted by **HARVEY B. LILLYWHITE** and **COLEMAN M. SHEEHY III**, Department of Zoology and Seahorse Key Marine Laboratory, University of Florida, Gainesville, Florida 32611-8525, USA; e-mail: hbl@zoo.ufl.edu.

ELEUTHERODACTYLUS RONALDI (NCN). CUBA: HOLGUÍN: FRANK PAÍS: Baconal, Sierra de Cristal (75°25'25.32"N, 20°34'35.04"W), ca. 600 m elev. 24 December 2000. A. Rodríguez and R. Alonso. Instituto de Ecología y Sistemática, Colección Zoológica de la Academia de Ciencias de Cuba (CZACC 1411402). Verified by L. V. Moreno. First record of the species in Sierra de Cristal and a range extension of ca. 45 km from the closest previous record in Cupeyal del Norte, Cuchillas del Toa (Garrido and Jaume 1984. Doñana, Acta Vertebrata 11:5–128).

Submitted by **ARIEL RODRÍGUEZ** and **ROBERTO ALONSO**, Instituto de Ecología y Sistemática Carr. de Varona, Km 3, Capdevila, Boyeros, AP 8029, CP 10800, Ciudad de la Habana, Cuba; e-mail: zoologia.ies@ama.cu.

ELEUTHERODACTYLUS TETAJULIA (NCN). CUBA: HOLGUÍN: FRANK PAÍS: El Desayuno, Sierra de Cristal (75°26'12.84"N, 20°31'54.48"W), ca. 700 m elev. 15–19 December 2000. A. Rodríguez and R. Alonso. Instituto de Ecología y Sistemática, Colección Zoológica de la Academia de Ciencias de Cuba (CZACC 1411403–4,1411407–11). Verified by L. V. Moreno. This record is a range extension of ca. 76 km W of the only previously known record at the type locality (Estrada and Hedges 1996. Herpetologica 52:435–439).

Submitted by **ARIEL RODRÍGUEZ** and **ROBERTO ALONSO**, Instituto de Ecología y Sistemática Carr. de Varona, Km 3, Capdevila, Boyeros, AP 8029, CP 10800, Ciudad de la Habana, Cuba; e-mail: zoologia.ies@ama.cu.

HYLA ALBOMARGINATA (White-edged Treefrog). BRAZIL: SANTA CATARINA: Municipality of Florianópolis: Ilha de Santa Catarina, Praia dos Naufragados (27°49'S, 48°34'W). 19 October 2002. A. Kwet and T. Miranda. Museu de Ciências e Tecnologia da PUCRS (MCP 6380–81), Porto Alegre, Brazil. Verified by M. Di-Bernardo. This first record for the island of Santa Catarina represents the southernmost locality for this species, which is widely distributed in the lower Amazon Basin and the Atlantic forests of eastern Brazil from Pernambuco to Santa Catarina (Frost 2002. Amphibian Species of the World: an online reference. V2.21 [15 July 2002] http://research.amnh.org/herpetology/amphibia/index.html). The new record extends the distribution ca. 150 km S from the previously cited southernmost locality near Guaramirim, northern Santa Catarina (http://www.ra-bugio.org.br/index.html). Four males were observed calling in a forest swamp with shallow water, ca. 300 m from the beach and perched on shrubs at heights of 1–2 m. One male took refuge in a large bromeliad (*Vriesea* sp.).

Submitted by **AXEL KWET**, Zoologie, Staatliches Museum für Naturkunde Stuttgart, Rosenstein 1, D-70191 Stuttgart, Germany (e-mail: axel.kwet@uni-tuebingen.de), **TATIANA MIRANDA**, Laboratório de Pesquisas Biológicas, PUCRS, Av. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA; e-mail: hsmith@colorado.edu.

RANA AURORA (Red-legged Frog). USA: ALASKA: Chichagof Island: SE of Hoonah: muskeg ponds with silty, organic bottoms surrounded by grasses and sedges. NMFS, Auke Bay Laboratory, Juneau, Alaska AB 02-21, 57°50'90.0"N, 135°03'8.3"W, 13 July 2002, Schroder, 2 subadults. Additional specimens include AB 02-82–87. Verified by Kelly McAllister and Bruce L. Wing.

This is the fist recorded *Rana aurora* from Alaska (Hodge 1976. Amphibians and Reptiles in Alaska, the Yukon and Northwest Territories, Alaska Northwest Publ. Co., Anchorage). Rumors among former Hoonah school students regarding the origin of the frogs surfaced. A former Hoonah school teacher allegedly released frogs, purchased form a biological supply company, into a pond near Hoonah. I located the former teacher in another city and the teacher confirmed he purchased one or two egg masses of *R. aurora* from Powell Laboratories (Carolina Biological Supply), Gladstone, Oregon , ca. 1982 and released a couple dozen froglets in a pond SE of Hoonah ca. 1982. Carolina Biological Supply staff confirmed that egg masses of *R. aurora* were collected in the Columbia River Gorge, Oregon and shipped from Powell Laboratories in Oregon to schools throughout the west during this time period.

The introduced *Rana aurora* are successfully reproducing and dispersing into adjacent wetlands. The effect this exotic introduction will have on native amphibians and other aquatic life remains to be determined. The genetic relationships of the Chichagof Island populations with Oregon populations merits investigation.

Ovaska et al. (2002. Herpetol. Rev. 33:318) recently documented *Rana aurora* from Graham Island in the Queen Charlotte Islands, British Columbia, Canada, speculating that these frogs might be introduced (although no record of such an event exists).

Rana aurora is the second exotic amphibian species introduced/ established in Alaska. *Pseudacris (= Hyla) regilla* (Pacific Treefrog) was human introduced on Revillagigedo Island in 1960 and is reproducing but apparently not dispersing into nearby wetlands (Norman and Hassler 1995. Unpubl. report, National Biological Service, Humbolt State University, Arcata, California). *Pseudacris regilla* also exists in the Queen Charlotte Islands as the result of human introduction.

Special thanks to Chuck Parsley, John Sargent, and staff of Hoonah USFS.

STEFANIA SCALAE (Rana de la Escalera). VENEZUELA: BOLÍVAR: Wareipita River, tributary of the Cucurital River, Canaima National Park (06°00'31"N, 62°47'01"W), 370 m elev. 25–28 September 2000. R. Rivero, E. La Marca, C. Molina, D. Lew, and H. Rojas. Museo de Historia Natural La Salle, Caracas, (MHNLS 14995,15001, 15022, 15041–42). Verified by J. Ayarzagüena. Until now, this species has been considered endemic to the La Escalera region in Venezuela between 860 and 1360 m elev. (Señaris et al. 1996. Publ. Asoc. Amigos Doñana 7:1–57; Gorzula and Señaris 1999. Scientia Guaianae No. 8, xviii + 268 pp., 32 pls.), although Barrio (1998. Act. Biol. Venez. 18[2]:1–93) tentatively assigned an unvouchered specimen from Cerro Santa Rosa, South Serranía del Supamo, Bolívar State to this taxon. These specimens were collected at night, above and under rocks or in the marginal vegetation, along a small rocky tributary of the Cucurital River. These new specimens are the first documented records outside the type locality and are from the lowest elevation recorded for this species. They extend the range at least 140 km to the east of the previously known locality.

KINOSTERNON BAURII (Striped Mud Turtle). USA: FLORIDA: FRANKLIN CO: On land near East River, a distributary of the Apalachicola River (29.8632°N 85.0223°W). 16 August 1991. M. A. Ewert. Florida Museum of Natural History (UF 139566) adult female. FRANKLIN CO: On land on Forbes Island across the Apalachicola River from Fort Gadsden Historical Site (29.9401°N 85.0158°W). 17 May 1993. M. A. Ewert. UF 139567, adult female, on its nest. GULF CO: On land ca. 300 m N of Forbes Island and Brickyard Cutoff of the Apalachicola River (29.9528°N 85.0223°W), 18 August 1991. M. A. Ewert. UF 139568, adult female, nesting. LIBERTY CO: On land next to stream 4.8 km N of S.R. 20, Bristol (30.5016°N 84.9869°W), 5 June 1999. D.R. Jackson. UF 139569, adult female. JACKSON CO: In Spring Creek, 2 km SE Marianna (30.7501°N 85.1983°W), 12 June 2002. G. Guyot. UF 139570, photographic voucher of adult female and UF 139571 preserved hatchling from an egg from this female. Data that support our identifications include 1) "plastral formula" scores that favor *K. baurii* or *K. subrubrum hippocrepis* rather than *K. s. subrubrum* (Lamb and Lovich 1990. Copeia 1990:613–618; Lovich and Lamb 1995. J. Herpetol. 29:621–624), 2) at least a partial mid-dorsal stripe on the carapace of two of the six specimens, 3) production of eggs and nesting during late summer and fall (no evidence of this for *K. s. hippocrepis* (e.g., Dundee and Rossman 1989. The Amphibians and Reptiles of Lousiana. Louisiana State University Press, Baton Rouge. 300 pp.), and 4) eggs with embryonic diapause (Ewert and Wilson 1996. Chelon. Conserv. Biol. 2:43–54), not present in *K. s. hippocrepis* (Ewert, pers. obs.). All five records extend the range of *K. baurii* westward in Florida from the St. Marks River drainage (Wakulla Co., Etchberger and Iverson 1989. Florida Sci. 52:119–144) into the Apalachicola River drainage, including the Chipola River. *Kinosternon baurii* is recorded for the Apalachicola (Flint River) drainage of Georgia (Jensen and Moulis 1999. Herpetol. Rev. 40:240–247). Our new records extend the total known range further west by 19' to 32' of longitude (from Calhoun Co., Georgia; Williamson and Moulis 1994. Savannah Sci. Mus. Spec. Publ. 3:1–712). All specimens were verified by M. J. Aresco.

LACERTILIA

COLEONYX VARIEGATUS (Western Banded Gecko). USA: ARIZONA: COCONINO CO: Wupatki National Monument: Deadman Wash, UTM (NAD27) 12S, 468940 E, 3932197 N, ca. 1390 m elev. 23 April 2002. Trevor B. Persons. Flagstaff Area National Monuments Vertebrate Collection, WUPA 24715. Kana-a Wash, ca. 0.25 mile E of Wukoki Ruin, UTM (NAD27) 12S, 470658 E, 3931404 N, ca. 1402 m. elev. 10 September 2002. Trevor B. Persons. WUPA 24722. Both verified by Charles A. Drost. Both specimens found under flat sandstone rocks in Great Basin Desertscrub habitat of Wupatki Basin. First records for the Little Colorado River basin, and first records from the Colorado Plateau away from the Colorado River (Dixon 1970. Cat. Am. Amph. Rept. 96.1–96.4; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, Third Edition. Houghton Mifflin Co., Boston, Massachusetts, 533 pp.). Brennan et al. (2002. Herpetol. Rev. 33:320) reported a specimen from Glen Canyon National Recreation Area NE of Page, Coconino Co., suggesting the species occurs throughout the Colorado River corridor in Arizona. These Wupatki specimens extend the range ca. 75 air km SE of the next furthest downstream Colorado River corridor record, Tanner Trail in Grand Canyon National Park (Miller et al. 1982. Amphibians and Reptiles of the Grand Canyon. Grand Canyon Nat. Hist. Assoc., Grand Canyon, Arizona). These records suggest the species occurs throughout the Little Colorado River valley between Grand Canyon and Wupatki, and may occur more widely in similar lower elevation habitats on the northern portion of the Navajo Indian Reservation. Because of the barrier imposed by the Mogollon Rim and Coconino Plateau to the south and west, respectively, the Little Colorado River valley probably represents the historical dispersal route from Grand Canyon of this and other desert species that reach their local terminus in the Wupatki area (e.g., *Sceloporus magister*, *Cnemidophorus tigris*, *Salvadora hexalepis*).

DAREVSKIA VALENTINI (Caucasian Rock Lizard, introduced species). USA: OHIO: VAN WERT CO: west Delphos at Killbros Equipment Company on Ohio Rt. 697, collected Aug. 1986, specimen KU 206727 (Natural History Museum and Biodiversity Research Center, University of Kansas). Specimen had been misidentified as *Podarcis muralis* (Common Wall Lizard) and mapped by Conant and Collins (1998. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Company, Boston, Massachusetts, 616 pp., and in the precursor edition of 1991) as originating from a population in NW Ohio. I visited the site of collection on 21–22 May 2002 and found no lizards there. Both a local naturalist, George Bilbrey, and a regional herpetologist, Eric Juterbock, confirmed that *Eumeces fasciatus* is the only lizard species recorded from Delphos. Killbros Equipment Company staff kindly identified the person who collected the specimen as James Brokamp, a former employee. In an interview he stated that in 1986 he was in charge of unwrapping arriving agricultural machines shipped to Kilbros. When he slit open the tight fitting plastic wrap covering a machine he found the lizard "between the wheels," seized it and kept it for a week. He then forwarded it to his sister-in-law in Lima, Ohio who was working for the Ohio State Park System, and she sent it to Cincinnati, from where it was further sent to Lawrence, Kansas. Brokamp stated there was a newspaper article in the Delphos Herald about him and his lizard which he unfortunately discarded two years ago. Despite kind help from the *Delphos Herald* editor, Susan Gerker, I was unable to retrieve the article from the newspaper archive. The Kilbros staff helped me track down the machine's itinerary starting from an Italian agricultural machine manufacturer (Bondioli & Pavesi S.p.A, Via 23 Aprile, 35, Suzzara, Mantova) via Virginia (Bondioli & Pavesi Inc., 104 Sycamore Drive, Ashland, Virginia) to Delphos. A reasonable explanation is that someone put the lizard in the wrapping of the machine on purpose, perhaps as a joke. An internet search revealed that there is a long history of commercial traffic of agricultural machines to Italy from the former Soviet Union, one of the home countries of *Darevskia*. However I was unable to track down the itinerary of the machine beyond Italy. I conclude that the *Darevskia* record in Ohio is based on a single specimen only and that no population ever was established there. For specimen descriptions see Deichsel and Bischoff (2002. Herpetol. Rev. 33:65) and Bischoff and Deichsel (2002. Salamandra 38[2]:113–117).

LEIOCEPHALUS CARINATUS ARMOURI (Little Bahama Curly-tailed Lizard). USA: FLORIDA: ST. LUCIE CO., NW side of intersection of U.S. Hwy 1 and Prima Vista Boulevard in the "St. Lucie Shopping Center" parking lot (27°19.601'N, 80°19.369'W), between the "Mobil" gas station and the "Prima Vista Professional Building." 4 October 2003. One individual (7.5 cm SVL male) observed 1456 h and collected 1507 h. C. L. Dean. Verified by Walter E. Meshaka, Jr. State Museum of Pennsylvania, Harrisburg (SMP-H2130). First record of this exotic species for St. Lucie County. Extends the range 23 km N of an allopatric population in Port Salerno, Martin County, discovered 31 August (SMP-H2108) (Dean et al. unpubl. rept.). Both of these sites are N of the previously known range that extends ca. 90 km along the Atlantic coastline extending from northern Broward County through Palm Beach County into southern Martin County (Smith et al. *In press*. Int. Biodet. Biodegrad.; Smith and Engeman, unpubl.). The U.S. Hwy 1 and Prima Vista Boulevard site likewise is ca. 113 km S of the most northern east coast of Florida population located in Cocoa Beach (Krysko and King 2002. Herpetol. Rev. 33:148); with no allopatric populations yet reported between these two locations.

Submitted by **CHRISTOPHER L. DEAN** and **HENRY T. SMITH**, Florida Department of Environmental Protection, Florida Park Service, 13798 S.E. Federal Highway, Hobe Sound, Florida 33455, USA, and **RICHARD M. ENGEMAN**, National Wildlife Research Center, 4101 LaPorte Ave., Fort Collins, Colorado 80521-2154, USA; e- mail: Richard.M.Engeman@aphis.usda.gov.

PANASPIS (LACERTASPIS) CHRISWILDI (Chris-Wild's Snake-eyed Skink). CAMEROON: TCHABAL MBABO-MASSIF: Summit. January 2000. Andreas Schmitz and Hans-Werner Herrmann. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 75735). Verified by Wolfgang Böhme. *Panaspis (Lacertaspis) chriswildi* was previously only known from its type locality, Mt. Kupe, South Cameroon (Böhme and Schmitz 1996. Rev. Suisse Zool. 103:767–774) and from the Takamanda Forest in southwestern Cameroon (ZFMK 68892). The new finding from the Tchabal Mbabo-massif in northern Cameroon represents the third known specimen of the species from this country, and the northernmost record of the species (it extends the known distribution ca. 350 km airline distance to the north). It was caught in gallery forest at 2000 m elev. Besides coloration and pattern, its 26 scales around the midbody, two pairs of nuchal scales, and 18–19 lamellae under the fourth toe are characteristic of *Panaspis (Lacertaspis) chriswildi*. The specimen is a male and has the largest snout–vent length (59.5 mm) so far recorded in this species. The specimen had fallen from a high branch (ca. 15 m above the ground) of a tree, situated at the edge of a small gallery forest.

Submitted by **ANDREAS SCHMITZ,** Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenaueralle 160, D-53113 Bonn, Germany (e-mail: A.Schmitz.ZFMK@uni-bonn.de).

SCELOPORUS UNDULATUS CONSOBRINUS (Southern Fence Lizard). MEXICO: CHIHUAHUA: Rancho Bros. Brown (= Rancho Los Nogales), Sierra de En Medio (31°10'32.6"N, 108°35'9.7"W), 1461 m elev. 19 September 2002. Julio A. Lemos-Espinal. Herpetological Collection of Unidad de Biología, Tecnología y Prototipos (UBIPRO) 10427–29. Verified by Richard L. Holland. First record for Chihuahua, extending its known range ca. 20 km S from its closest known locality in southwestern New Mexico (Lemos-Espinal et al. 2000. Bull. Maryland Herpetol. Soc. 36:133–138; Lemos-Espinal et al. 2001. Bull. Chicago Herpetol. Soc. 37:29-31). At this time, we do not follow Leaché and Reeder's (2002. Syst. Biol. 51:44–68) assessment that the name of this taxon should be *S. cowlesi*.

Submitted by **JULIO A. LEMOS-ESPINAL** (under CONABIO projects U003, X004, AE003), Laboratorio de Ecología, UBIPRO, Facultad de Estudios Superiores Iztacala, UNAM, Apdo. Herpetofauna of Isla de La Plata, Ecuador

OMAR TORRES-CARVAJAL
Natural History Museum & Biodiversity Research Center and Department of Ecology and Evolutionary Biology The University of Kansas, Lawrence, Kansas 66045-7561, USA
e-mail: otorres@ku.edu

La Plata is a 14.2-km^2 island situated 27 km from the Ecuadorian coast (01°16'S, 81°06'W). This small island is part of Machalilla National Park, located in Provincia Manabí, and is formed by a volcanic rock base similar to basalt (Tickell 1990). The highest point on the island is 167 m. From December to May, La Plata is characterized by high temperatures and heavy rains, whereas the rest of the year it is dry and cooler. The island vegetation is composed of species typical of Tropical Desertic Thicket (Cuéllar 1991), such as *Cordia lutea*, *Lantana peduncularis*, *Bursera graveolens*, *Capparis flexuosa*, and *Prosopis juliflora*.

The terrestrial herpetofauna of Isla de La Plata comprises three species of lizards and two species of snakes including a new record for Ecuador. These species have been reported for the Ecuadorian western lowlands except for the new snake record (Coloma et al. 2000; Pérez-Santos and Moreno 1990; Torres-Carvajal 2001). Although several species of birds and plants of Isla de La Plata also occur in the Galápagos Islands (Ortiz-Crespo and Agnew 1992; Tickell 1990), none of the species mentioned herein is present in the Galápagos. Fieldwork at Isla de La Plata was conducted in March 1995. In addition, I examined specimens deposited in the Museo de Zoología, Pontificia Universidad Católica del Ecuador, Quito (QCAZ). Luis A. Coloma and Chris Sheil verified the identification of specimens.

Ameiva edracantha. August 1990. A. Carrera, A. Lansdale, and G. Romero. QCAZ 941, 1157; March 1995. M. C. Terán and O. Torres-Carvajal. QCAZ 2847–48; May 1998. X. Cisneros and O. Bastidas. QCAZ 3967. Erroneously reported as *Amevia* sp. by Tickell (1990).

Microlophus occipitalis. August 1990. J. Ashworth. QCAZ 943, 944; August 1990. A. Carrera, A. Lansdale, and G. Romero. QCAZ 1158–60; March 1995. M. C. Terán and O. Torres-Carvajal. QCAZ 2875–77.

Phyllodactylus reissii. August 1990. A. Carrera, A. Lansdale, and G. Romero. QCAZ 942; March 1995. M. C. Terán and O. Torres-Carvajal. QCAZ 2849–51, 2874. Reported as *Phyllodactylus* sp. by Tickell (1990).

Mastigodryas melanolomus. August 1990. A. Carrera, A. Lansdale, and G. Romero. QCAZ 945–46. Erroneously reported as *Liophis albicara* by Tickell (1990) and Núñez et al. (1994). First record for Ecuador; extends range ca. 970 km SW of nearest recorded locality, Ibagué, Departamento Colima, Colombia (Pérez-Santos and Moreno 1988). This new record increases the number of Ecuadorian colubrid snakes to 159 and the number of species of Ecuadorian snakes to 224 (Coloma et al. 2000).

Oxybelis aeneus. August 1990. A. Carrera, A. Lansdale, and G. Romero. QCAZ 947. Reported as *Oxybelis* (*brevirostris* or *seneus* [lapsus for *aeneus*]) by Tickell (1990).

Acknowledgments.—I thank INEFAN for permission to collect in Machalilla National Park in 1995. Fieldwork was partially funded by Fundación Natura, Asociación de Escuela de Ciencias Biológicas (PUCE), Asociación de Escuela de Ciencias Exactas y Naturales (PUCE), and INEFAN. I am grateful to Laura Arcos, Luis Coloma, Gerardo Corrales, María Cecilia Terán, Jean-Marc Touzet, Linda Trueb, Carlos Zambrano, and Machalilla National Park personnel and fishermen for their comments and help.

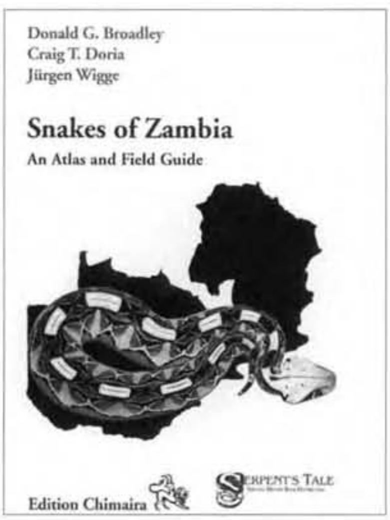
STEPHEN SPAWLS
44 Templemere
Norwich NR 3 4 EF, England
e-mail: stevespawls@hotmail.com



Zambia was once described to me by a cynical traveller as "a thousand miles of featureless bush, sandwiched between two waterfalls," although those falls are Africa's most spectacular, Victoria Falls, on the Zambian/Zimbabwe border, and Africa's highest, Kalambo Falls, on the Zambian-Tanzanian border. Certainly Zambia is a fairly flat country; most of it lies between 1000 and 1600 m elevation on the south central African plateau, although there is a small area of land over 2000 m in the northeast, in the western foothills of Malawi's Nyika Plateau. Much of the country is covered by woodland, dominated by *Brachystegia* trees (Miombo woodland) and Mopane (*Colophospermum mopane*), and rainfall is more or less uniform (800–1600 mm annually) throughout the country. However, the country contains some notable conservation areas and important wetlands. Zambia (formerly Northern Rhodesia) is the bridge between the east African and southern African herpetofauna, and an element of the central African forest fauna also occurs there, extending southwards out of the forest into the thick woodland on the Copperbelt and westwards from there along the border with the Democratic Republic of the Congo. The Zambian snake fauna seems somewhat impoverished—89 species or 0.118 species per 1000 km^2. In comparison, snake species densities for other African countries for which snake faunas are well known include: Uganda (0.402 species/1000 km^2), Kenya (0.206 species/1000 km^2), Zimbabwe (0.202 species/1000 km^2), Tanzania (0.154 species/1000 km^2), and Ethiopia (0.083 species/1000 km^2).

This handsome book fills an important niche in the documentation of the African herpetofauna; a task that is only just getting underway. Previously, little was available dealing directly with Zambian reptiles, save Pitman's speculative checklist (1934), Desmond Vesey-Fitzgerald's enjoyable anecdotal paper on his experiences while based at Abercorn, now Mbala, in northern Zambia (1958), and Wilson's 1965 paper on a big snake collection from eastern Zambia. In 1971 Don Broadley authored what remains the only comprehensive checklist of the reptiles and amphibians of Zambia (Broadley 1971), listing 74 species of snake, and in 1990 Don made a definitive collecting trip to the Mwinilunga area, a small projection extending up into the southern Democratic Republic of the Congo (Broadley 1991), this trip added several new species to the Zambian total. The relevant literature is rounded out by two small locally produced books, one dealing chiefly with common fishes, amphibians, and reptiles (Simbotwe and Mubamba 1993), and another on the snakes of Luangwa Valley (Doria and Nyirenda 1995). Doria, a game ranger in the Luangwa Valley Reserve in Zambia and Wigge, a medical doctor working in Zambia at the time, had the original idea for the volume under review here. They recruited Don Broadley for his systematic expertise and the book is largely the result of his efforts and is stamped with his customary thoroughness and scholarly professionalism.

The book opens with a table of contents (listing all species), a preface, and six pages on "The Zambian Environment," four pages of which are occupied by eight half-page color plates showing Zambian habitats. The text of this last section includes some brief zoogeographical data, mentioning the central African influence and the montane species found on the Nyika Plateau. Interestingly, none of the habitat plates shows a single hill, indicating the flatness of the Zambian landscape. There follows a map of Zambia showing provinces and important localities, ten pages of snake biology, a systematic list (which more or less duplicates the table of contents) and ten pages of keys. The description of the 89 known Zambian snake species occupies the bulk of the book (195 pages). This section includes 162 pictures, all half-page and nearly all color, illustrating 77 species. Each species description opens with a short summary paragraph followed by information presented under the headings: Description, Size, Colour, Distribution and Preferred Habitat, Field Notes, and Comments. For a number of species, especially the dangerous ones, this final section contains some remarkable and enjoyable anecdotes about the snakes, many contributed by Craig Doria, who as a wildlife professional in the Luangwa (one of Africa's most spectacular national parks), had regular close encounters with snakes. I particularly enjoyed the story on page 123 of how a Zambian game scout spat back at a Mozambique spitting cobra and was delighted to find out that the supposed "call" of the black mamba is actually that of the Pigmy Rail. There are some elegant turns of phrase, for example "The large elapids are the kings of African snakes, and … have an intelligent presence when encountered…" (p. 98). Accompanying most of the descriptions (53 of 89) is a set of three line drawings showing the head scales of the species from above, below, and in profile, in the style popularized by V.F.M. FitzSimons.

The book concludes with a 21-page section on snakebite (venoms, antivenoms, notes on individual venomous Zambian snakes and case history details, avoiding snakebite, first aid, medical treatment and use of antivenom), a seven-page bibliography, a two-page glossary, and two somewhat repetitive indices, one of scientific and vernacular names in that order and the other in the reverse order. The back cover is graced by photographs of the three authors. I was greatly pleased to see the one of Don Broadley, one of Africa's most prolific herpetologists but also one its most mod-

est; a published photograph of him is as rare as some of the snakes described in this book.

The book itself is well-written and very nicely produced. It is strongly bound, with good firm covers, and printed on glossy paper. As is usual with Chimaira publications, the photographic coverage is generous, with over 170 half-page color plates. Taken by a variety of photographers, the plates are astonishing. There are snakes here never before illustrated in color, or indeed in any form—animals like *Prosymna angolensis*, *Duberria shirana*, *Grayia ornata*, and *Natriciteres bipostocularis*. There are also color phases that I have never seen before, such as a vivid rufous *Dasypeltis scabra*, a green *Thrasops jacksoni*, a blue-and-orange barred *Philothamnus semivariegatus*, a startling color phase of *Boulengerina annulata* from Stanley Pool, and a curiously dark *Rhamphiophis rostratus*. The last of these is a species I have collected at opposite ends of its range, in Kenya and Botswana, and neither looked anything like the specimen shown here.

The book has a few shortcomings. I am a great believer in the adage "Something is better than nothing," and would rather see a poor picture of a previously unknown animal than nothing at all. In general, too, the quality of illustrations in this book is high, but there are a number which are rather poor. This is acceptable where there is no alternative, but, for example, in the illustration of the *Amblyodipsas ventrimaculatus* (p. 85), the head is out of focus and Don himself has a better picture in his "Snakes of Zimbabwe" (Broadley and Cock 1982). There are also better pictures available of the Bark Snake, *Hemirhagerrhis nototaenia*, than the soft-focus one on page 153. Many of the snakes illustrated are obviously dead, particularly those photographed by Woody Cotterill. These photos were taken on Broadley's expedition to Mwinilunga and the explanation behind them is a story typical of Africa. Don and Woody were crossing the Zambezi Valley and most of these snakes were alive when their Landrover broke down. The snakes died in the intense heat forcing Woody to hurriedly photograph them before Don preserved them by the side of the road.

The picture choice seems overindulgent in places, there are four pictures of *Bitis nasicornis*, a snake of doubtful occurrence in Zambia, and four Puff Adder pictures, none of which were taken in Zambia; a photograph of a Zambian specimen of this common species should have been available. In fact, of the 162 snake pictures, only 61 were actually taken in Zambia, with many of the rest from surrounding countries. The color in some of the pictures is startlingly different to the color of the same pictures as used in "Snakes of Zimbabwe." For example, the Snouted Night Adder (p. 64) is lying on a piece of blue cloth; in the same photograph in the Zimbabwe book the cloth is gray!

There are a few typos and minor errors in the text and some room for additional information. The descriptions of all the species run on without any generic introductions. I felt that a few of the pictures could have been dropped in favor of such accounts, which could give an overview of the genus. A gazetteer would also have been useful to find important localities like Mpulungu, Isombu Stream, and Isoka. Figure 56 is a *Dasypeltis scabra*, not a *Thelotornis*, and I laughed to find *Hemirhagerrhis* (admittedly a difficult name) spelled three different ways on pages 152 and 153, as Don Broadley and Barry Hughes have chided me in print for misspelling this same name (Broadley and Hughes 2000)! There are some odd common names in this book. For example, the authors call *Rhamnophis aethiopissa* the "Splendid Dagger-tooth Tree Snake," a magnificent name but myself and colleagues (Spawls et al. 2001) and Pitman (1974) have called it Large-eyed Green Tree-snake, I don't see any benefit in changing it; the epithet "Splendid" doesn't convey anything specific and a lay observer doesn't see the dagger-like teeth. I like common names, they make the subjects accessible to the layperson. I have coined a few myself, but I feel that they should convey something about the animal, and if a well-used common name exists, it is worth sticking to it (Spawls et al. 2002:27). The pictures in this book (which is what a layperson looks at first) are labelled with scientific names only, making cross referencing with the relevant text more difficult for non-specialists than it need be.

But these are minor criticisms and do not detract from the importance of this sound and professional work. This is a book that all Zambian naturalists will want, as well as all herpetologists interested in Africa. It will raise the profile of the Zambian herpetofauna and, as I never tire of saying, if anything will help save and protect Africa's wonderful and yet severely threatened flora, fauna, and wild places, it is the emergence of enthusiastic local naturalists who feel that the preservation of such things is worthwhile; books like this will help nurture their enthusiasm. The authors and the publisher deserve credit for making this information available in a popular form. I only hope the book will be available in Zambia.

Erratum

The captions accompanying photolithographs of *Corallus caninus* by Will Brown in the last issue of HR (34:331) were reversed. Thus, the uppermost figure depicts an Amazonian Basin snake, while the lower figure is that of a snake from Guyana.
